PINEAPPLE, the esculent fruit of the *ananassa sativa* (Lindley) from tropical America, and belonging to the natural order *bromeliaceæ*, which is composed of endogens with 6-leaved flowers having imbricated divisions and mealy albumen. The habits of the several species in this order are peculiar; they are hard dry-leaved plants, often with a scurfy surface, and capable of enduring great heat and continued dryness, yet producing blossoms distinguished for beauty and fragrance. The characters of the order are: calyx 3-parted, sometimes colored; petals 3, colored, withering or deciduous; stamens 6, inserted in the tube of the corolla and calyx; ovary 3-celled, many-seeded; seeds always numerous, with a leathery skin or tapering into a slender thread. The pineapple may be considered the most remarkable of all the species. It is an indigenous plant in the woods of South America, and from thence has been carried to Africa and to the East Indies, where it now forms a part of the naturalized flora. The pineapple fruit, structurally regarded, is no more than a cluster of flowers arranged upon an elongated axis of inflorescence, and terminating in a tuft of green leaves; each flower and its accompanying bract become thickened and fleshy, and as there are many on the spike, this increase causes a crowding together and swelling out of the whole until a massive head of individual flowers changed into a sort of berries is the result; the withered tips of the petals remain and give to the rhomboidal-shaped divisions of the fruit the appearance of an eye, technically called by gardeners the pip. In the wild condition each of these contains seeds; but long cultivation and stimulating soils have obliterated the disposition to bear seeds, a condition to which other vegetables or fruits are frequently reduced, as in the seedless varieties of the grape, orange, &c. By these means the crown of leaves and the suckers at the base of the fruit are required to propagate new plants, and new varieties must be expected from plants growing wild or in such a condition as to allow the perfection of the ovules instead of the carpel-like and pulpy envelopes. The pineapple has been extensively the subject of the gardener's care, especially in Great Britain, and many contrivances have been invented to raise it in perfection. The chief considerations seem to be a good, rich, loamy soil, warmth applied to the roots, abundance of water and moisture in a high temperature, supply of liquid stimulants when in a growing state, and less water and more air when the fruit is ripening. It is said that fruits thus raised in glass structures called pineries are far superior in point of flavor to any which grow in the open air, although the wild sorts found in parts of the East Indies are highly praised. In the Azores, the pineapple is raised in pots, which are set in the open air in summer, and protected in winter from the cold by merely a structure with a glazed roof known to gardeners as a lean-to. The varieties in the London horticultural society's catalogue are more than 50 in number, but those particularly recommended are the queen, Antigua, queen, black Jamaica, and Moscow; and the largest fruited are the Enville and Trinidad.—The juice of the unripe fruit of the pineapple is excessively acid and excoriating to the mouth. It is sometimes employed along with allied species, the *bromelia pinguin*, and others, to destroy intestinal worms and to promote the secretion of urine; and from the fibres of the leaves of the *ananassa* very fine cloth is manufactured.—The representative of the *bromeliaceæ* in the United States is the Spanish moss (*Tillandsia usneoides*, Linn.) of the south, and several other species known as air plants occurring in southern Florida.

PINEL, Philippe, a French physician, born at St. Paul, near Lavaur, department of Tarn April 20, 1745, died in Paris, Oct. 25, 1826. He was the son of a physician, and studied in several colleges, supporting himself meanwhile by private teaching. In 1778 he removed to Paris, where he gave lessons in mathematics, devoted every leisure moment to medical investigation, and wrote for the medical and the philosophical journals. His proposal for a new classification of animals, based on the formation of the jaw bone, gave him so much reputation as to make him a competitor with Cuvier for a professorship at the *jardin des plantes*. In 1785 he was led to turn his attention to insanity, and, taking charge of a private asylum for the insane, he tried with success, for 6 years, the substitution of gentle measures for the harshness then almost universally practised. In 1791 he obtained a prize from the society of medicine for the best essay on the treatment of insanity, and soon afterward was appointed physician of the Bicêtre. This immense establishment was a prison, almshouse, hospital, lunatic asylum, and nursery, all in one; and the different classes of inmates were suffered to mingle with one another. It was crowded almost beyond endurance, while many of the buildings were utterly unfit to be inhabited. The insane were chained in dark, damp, and filthy cells, and their keepers were malefactors condemned to this duty as a punishment for their crimes. It was very rare that a lunatic recovered. Under Pinel's administration each class was confined to its own quarters, the worst portions of the buildings were torn down, and the remainder thoroughly repaired and cleansed. The improvement in the condition of the insane was, however, the object at which he especially aimed; and this he was compelled to attempt in person, for cruelty had rendered the unhappy creatures so ferocious that no one durst set them at liberty. The number of cures he accomplished, even among these chronic cases, astonished the profession; and the method of treatment he introduced has been adopted in all civilized countries. After two years he was transferred to the Salpêtrière, a similar institution for females. His works on diseases of the mind gave the first decided impulse to that investigation of insanity which has conferred so much honor upon the medical science of the present day. At the death of Cuvier he succeeded him as a member of the academy of sciences. He was the author of 24 medical treatises, 6 of which were on insanity and cognate topics, and 13 or 14 on the mechanism of the joints, and other subjects connected with animal mechanics.

PINEROLO, or Pignerol, a city of Italy, in the province of Turin, on the Clusone, 20 m. S. by W. from Turin; pop. in 1860, 15,494. It has 6 churches, 9 convents, and manufactories of silk, wool, cotton, &c. It came into the possession of the house of Savoy in 1042, but was several times conquered by the French, who held it from 1536 to 1574, from 1632 to 1696, and from 1801 to 1814. The conquerors during the 17th century considerably strengthened its fortifications, but dismantled them on being obliged to give it up.

PINES, Isle of. I. (Sp. *Isla de Pinos.*) An island near the S. W. extremity of Cuba, 65 m. in extreme length, and 45 m. in breadth; area, 1,200 sq. m.; pop. in 1864, 1,400. Nueva Gerona, the capital, is situated on the N. side, and the other places of most importance are Santa Fé and Jorobado. It is separated from Cuba by a channel about 35 m. wide, and the coasts are indented by numerous bays, many of which afford good anchorage. There are several mountains, the most remarkable of which are the Sierra de la Cañada, the Daguilla, and the Sierra de los Caballos, respectively 1,600, 1,500, and 1,074 feet above the sea. Extensive tracts of marsh extend across the centre of the island in an E. and W. direction; the soil in other places is exceedingly fertile. It is well watered, and some of the rivers are navigable for vessels drawing 10 feet 4 or 5 m. from the sea. The climate is mild and healthy. There are mines of iron, silver, and quicksilver, and sulphur, rock crystals, and marble are found, the last of many colors and excellent quality. Tobacco and different kinds of fruit are grown, and timber is abundant, the most valuable descriptions being pine, mahogany, and cedar. The island is a dependency of Cuba. Columbus discovered it in 1494; and it was afterward much frequented by pirates. II. An island of the Pacific ocean, about 42 m. in circumference, situated near the S. E. extremity of New Caledonia; lat. of the peak on the S. E. part 22° 38' S., long. 167° 25' E.; pop. estimated at 2,500. Many kinds of fine timber grow on the island, among others a pine similar to that of Norfolk island, and sandal wood. The natives are middle-sized, of a dark color, and of the Papuan race, like the Feejee islanders, whom they much resemble. The males are circumcised, and both sexes go nearly naked. They are cannibals, and are exceedingly cruel and ferocious.

PINGRÉ, Alexandre Gui, a French astronomer, born in Paris, Sept. 4, 1711, died in 1796. He received his education at a convent school in Senlis, and early became a teacher of theology; but having embraced Jansenistic opinions, he was compelled to abandon this career, and devoted himself to astronomy. He published, from 1754 to 1757, under the name of *État du ciel,* a valuable nautical calendar; and after verifying La Caille's table of modern eclipses in the *Art de vérifier les dates,* he computed the similar phenomena that had occurred in the 10 centuries preceding our era. From 1760 to 1776 he made scientific voyages to observe transits of stars, and to ascertain the value of Berthoud and Leroy's timepieces. In 1783 he published his *Cométographie, ou traité historique des comètes* (2 vols. 4to.), upon which he had been engaged for several years. He calculated the orbits of 24 comets. In 1786 appeared his translation of Manilius's *Astronomica.*

PINK, the common name of varieties of the *dianthus caryophyllus* (Linn.), which in its natural condition grows wild in the south of France and in England, where it is met with on old ruinous walls. The pink is of the natural order of *caryophyllaceæ,* which are herbaceous plants with swollen articulate stems; opposite, entire leaves; regular flowers; sepals 4 or 5, and petals the same; stamens 5 or twice as many; styles 2 to 5; fruit a capsule; seeds curved, with a mealy albumen. They are natives chiefly of the frigid and temperate parts of the world. The 4 principal varieties of the pink are the double-flowered, called the carnation; the fruticose or tree carnation; the imbricated or clove, of a dark sanguineous color, with the stigmas protruding beyond the petals, and of delicious fragrance; and the thistle-like (*carduinus,* Don), with leaves, calyx, and petals beset with fistulous spines. The carnations are themselves divided into 3 classes, viz.: flakes, in which there should be 2 colors, the stripes of the blossoms going quite through the petals; bizarres, the flowers variegated in irregular stripes and spots, and having 3 distinct colors; and picotees, the flowers having a white ground spotted with scarlet, red, purple, or other colors; the last named are hardier than the others, with smaller blossoms and their margins serrated. The original type of the common garden pink is the *dianthus plumarius* (Linn.), with a stem bearing 2 or 3 flowers, the teeth of the calyx obtuse, calycine scales somewhat ovate, very short, mucronulate, close pressed; petals jagged, multifid, bearded; leaves linear with scabrous margins. It is supposed to be a European plant, but from what country is uncertain. Its flowers are more or less fringed, sweet-scented, double, single, white, purple, spotted, and variegated. Two principal varieties are known, viz.: *hortensis* (De C.) with petals bearded in the throat; and *pratensis* (De C.), with smaller leaves and petals scarcely fringed. The garden pink has been greatly improved by the florists within a century past, having been before treated as a border plant. Some beautiful sub-varieties known as Paisley pinks are hybrids originating in that part of Scotland among the weavers and artisans; and the sorts most esteemed by them are what are called pheasant eyes, from a dark spot in the centre of the blossom, and the nearer this approaches to black the more it is valued. Between 200 and 300 sorts are enumerated. An intermediate form between pinks and picotee carnations is called the cob pink, which is of large size and much prized. The carnation and pink delight in a rich loamy soil inclining to sandy, and require but little protection, wintering well in cold frames. They are propagated by cuttings, layers, and seed. The superb pink (*D. superbus,* Linn.) has green, smooth, linear-lanceolate leaves, sweet-scented flowers borne on branching stems in twos or threes, the petals rose purple or lilac; it grows spontaneously on heaths and borders of forests in mountainous countries of Europe. A variety with purple flowers is known. Several others of the dianthus tribe are called pinks, but their scentless flowers and rather different mode of inflorescence cause them to be treated with less consideration. Some new and very curious varieties of the *dianthus Chinensis* have lately come into notice, known as Japan pinks, of which *D. Hedwigii*, *laciniosus*, and *monstrosus* are examples; the style of the plants, their glaucous foliage, and stiff, upright, patulous blossoms, do not recommend them.

PINKERTON, John, a Scottish author, born in Edinburgh, Feb. 17, 1758, died in Paris, March 10, 1825. He was intended for the legal profession, but having established himself in London in 1780, he entered upon a literary career of singular activity. After publishing some trifles in verse under the title of "Rimes" (8vo., 1781), he edited "Select Scottish Ballads," many of the pieces in which he subsequently confessed were his own composition, succeeded by more volumes of verse, an "Essay on Medals" (2 vols. 8vo., 1784), once a useful manual for numismatists, and "Letters on Literature, by Robert Heron" (8vo., 1785). The last named work, exemplifying a new system of English orthography, procured him the acquaintance of Horace Walpole and Gibbon. He next edited "Ancient Scottish Poems" (2 vols. 8vo., 1786), published from the MS. collections of Sir Richard Maitland, and long supposed to be forgeries, although their genuineness is now authenticated. In 1787 appeared his "Dissertation on the Origin and Progress of the Scythians or Goths," which, with the "Inquiry into the History of Scotland preceding the Reign of Malcolm III." (2 vols. 8vo., 1789), is chiefly remarkable for the strong anti-Celtic feeling of the author, who undertakes to prove that the Celts were an inferior race to the Goths, "being mere savages, but one degree above brutes." His "History of Scotland from the Accession of the House of Stuart to that of Mary" (2 vols. 4to., 1797) is less colored by prejudice, and is still considered the most accurate history of the period. After the death of Walpole he collected and published notes of the conversation of his patron, with a memoir, in 2 vols. 12mo., under the title of "Walpoliana." Among his remaining works were the "Medallic History of England to the Revolution" (4to., 1790); "Iconographia Scotica" (2 vols. 8vo., 1799); "Modern Geography digested on a New Plan" (2 vols. 4to., 1802); "General Collection of Voyages and Travels" (17 vols. 4to., 1808–'13), accompanied by a "New Modern Atlas," published in parts (1809–'15); and "Petralogy, or a Treatise on Rocks" (2 vols. 8vo., 1811). In addition to these he edited 3 volumes of scarce Scottish poems, Barbour's "Bruce," "Lives of Scottish Saints," &c. The last 22 years of his life were passed in Paris, where, notwithstanding his ceaseless industry, he died in indigent circumstances. He was a man of vigorous intellect and very considerable historical and antiquarian learning, but full of prejudices. He is described as "a very little and very thin old man, with a very small, sharp, yellow face, thickly pitted by the small pox, and decked with a pair of green spectacles." His literary correspondence was edited by Dawson Turner (London, 18[illegible]).

PINKNEY, William, an American lawyer, born in Annapolis, Md., March 12, 1764, died Feb. 22, 1822. His family was a branch of the South Carolina Pinckneys, and early settled at Annapolis. He studied medicine in Baltimore, but in 1783 resolved to devote himself to law, and was called to the bar in 1786. His very first efforts gave him a marked position. In 1788 he was elected a delegate to the convention which ratified the constitution of the United States, and subsequently held various state offices in the house of delegates, senate, and council. In 1796 he was sent to London by President Washington as commissioner under the Jay treaty, remaining abroad until 1804, when he became attorney-general for the state of Maryland. He was sent minister to England in 1806, and held that office till 1811, when he was appointed attorney-general of the United States by Mr. Madison. He held this office over two years, and resigned it in consequence of an act of congress requiring the attorney-general to reside at Washington. He commanded a volunteer corps in the war of 1812, and was severely wounded at the battle of Bladensburg. In 1815 he was a member of congress, and in 1816 was appointed minister to Russia and special minister to Naples, returning home in 1818. The following year he was elected a member of the U. S. senate, where he made two elaborate speeches on the Missouri question, and was a member of the committee of conference that reported the Missouri compromise, which he strongly advocated. At the time of his death Mr. Pinkney was by general acknowledgment at the head of the American bar, occupying very nearly the same position that was held by Daniel Webster some years later. His "Life" was written by Henry Wheaton (New York, 1826).—**Edward Coate**, son of the preceding, an American poet, born in London, during the temporary residence there of his father as American commissioner, in Oct. 1802, died in Baltimore, April 11, 1828. He was educated at St. Mary's college, Baltimore, and at the age of 14 entered the navy as a midshipman. In 1824 he resigned his commission, was married, and commenced the practice of the law. Failing in this, he attempted unsuccessfully to procure a commission in the naval service of Mexico; and in 1827 he assumed the control of a political journal called "The Marylander," which from ill health he was soon obliged to relinquish. His poetical reputation rests on a volume entitled "Rodolph and other Poems," published anonymously in 1825. Some of the songs in this, including the "Health" and the "Picture Song," still have great popularity.

PINT, a measure of capacity, being the 8th part of a gallon. (See Gallon.)

PINTADO. See Guinea Fowl.

PINTELLI, Baccio, an Italian architect, born probably in Florence about the middle of the 15th century, died probably in Urbino about the commencement of the 16th century. He was the principal architect of Pope Sixtus IV., for whom he erected about 1473–'5 the Sistine chapel. He also designed the church and convent of Santa Maria del Popolo, the old library of the Vatican, the churches of San Pietro in Vincoli, Santa Maria della Pace, and Sant' Agostino, the Ponte Sisto over the Tiber, &c. After the death of Sixtus he went to Urbino, and was engaged upon the ducal palace of that city.

PINTO, Mendes. See Mendez-Pinto.

PINTO DE FONSECA. See Chaves, Marquis of.

PINTURICCHIO, Bernardino, an Italian painter, born in Perugia in 1454, died in 1513. He was a pupil of Perugino, and one of the best painters of the Roman or Umbrian school previous to the time of Raphael, excelling in portraits, history, and architectural accessories. He executed portraits of Popes Pius II. and Innocent VIII., Isabella the Catholic, and other eminent personages, but is chiefly distinguished by his history of Pius II., painted in 10 compartments of the Duomo of Sienna, and in which he was assisted by Raphael.

PINY WOODS, a term applied to several very different regions of country in the southern states of North America, but more particularly to that broad belt of territory extending from 60 to 100 m. inland from the N. shore of the gulf of Mexico, and including nearly the whole of West Florida, with the southern parts of Alabama and Mississippi, and the S. E. corner of Louisiana. Portions of East Florida, Georgia, and the Carolinas partake, in a greater or less degree, of the same general features. This region is but little cleared and cultivated. Its characteristics are entirely different from those of the adjacent cotton districts. The soil is sandy and barren, and the predominant and to a great extent almost unvaried growth is pine, both in the hill and level portions, for there is a great diversity of surface. The absence of undergrowth allows the eye a wide range of vision, and gives to these forests a singularly stately appearance. The borders of the streams and swamps are fringed with a thick growth of magnolia, bay, laurel, and other evergreens. "Bay-gall" is the provincial term commonly applied to the smaller of these swamps or thickets—often the source of streams—which constitute a familiar feature of the country. It is here that the deer and other game, which are rare in the open woods, find a refuge. Open glades, or savannas, of greater or less extent, are frequently met with. A curious phenomenon occasionally occurring in these woods consists of a circle of trees, of an acre or less in extent, entirely dead, without any apparent cause. This is variously attributed to the effects of lightning or the ravages of insects. The brooks and rivulets of the piny woods consist of the purest and most limpid water. The atmosphere is singularly healthful and exhilarating, and the exhalations from the pine are believed to possess properties positively curative of incipient pulmonary disease. The population is small and scattered, on account of the unproductiveness of the soil. Of late years, however, there have been large accessions to the amount of labor and capital employed in obtaining timber and turpentine, as well as, to a limited extent, in the cultivation of the land.

PINZON, the name of a family of wealthy and daring navigators in the port of Palos de Moguer in Andalusia, 3 members of which were intimately associated with Columbus in his discovery of America. I. Martin Alonso, the head of the family at that time, was so convinced of the feasibility of the project, that he offered to afford the means for Columbus to renew his application to the court. When the latter had obtained the royal order to fit out 3 vessels for the voyage, it was principally through the influence of the Pinzons that crews could be collected for them. Martin Alonso commanded the Pinta on this voyage. In the subsequent cruising in search of the imaginary island of Babeque, he deserted Columbus in the latter part of Nov. 1492, and went in search of it himself. He stopped at a river in Hispaniola, now called Porto Caballo, but which for a long time was designated as the river of Martin Alonso. From here he carried off 4 men and 2 girls with the intention of selling them in Spain as slaves, but was afterward forced to give them up by Columbus, with whom he fell in during the following January, attributing his parting company with the admiral to stress of weather. On the return voyage they were again separated by a storm, and Pinzon was driven into the port of Bayonne. Not doubting that Columbus had perished in the tempest, he wrote to the sovereigns, giving information of the discovery, and asking permission to come to court and deliver his account in person. He arrived in Palos the evening of the same day with the admiral, and found that the latter had had a triumphant reception. He landed in private, and, broken in health and spirits, received not long after a letter from his sovereign forbidding him to appear at court. This added to his dejection, and soon after he died. II. Vicente Yañez, who had commanded the Niña in the first expedition of Columbus, in consequence of the general license given by the Spanish sovereigns to make voyages of discovery, fitted out an armament of 4 caravels, manned principally by his friends and relations, and in Dec. 1499 sailed from Palos in a S. W. direction. After having gone about 700 leagues, he crossed the equinoctial line and lost sight of the north star. On Jan. 26, 1500, land was descried; it was Cape St. Augustine. Pinzon was thus the first European to cross the equator in the western ocean, and the first discoverer of Brazil. Landing, he took formal possession of the country for the Castilian crown; but being resolutely met by warlike natives, he sailed to the N. W., and after various adventures reached the mouth of the Amazon. Pursuing his course, he passed the mouth of the Orinoco, and in the latter part of June reached Hispaniola. In the following month two of the caravels were sunk with their crews in a terrific hurricane. Pinzon arrived in Palos about the end of September, after a disastrous voyage, which had swallowed up all his fortune. On Sept. 5, 1501, royal permission was given him to colonize and govern all the country he had discovered from Cape St. Augustine to a little north of the Amazon, but he never made a second expedition into those parts. In 1506 and again in 1508 he was concerned in voyages to discover the passage which Columbus supposed to lead from the Atlantic to a southern ocean. III. **Francisco Martin**, the third brother, accompanied the first expedition of Columbus, as pilot of Martin Alonso's vessel, the Pinta.—By the emperor Charles V. the Pinzon family were raised to the rank of hidalgos, in reward for the services in discovery its members had rendered. It still exists in Moguer near Palos.

PIOMBO, Fra Sebastiano del, an Italian painter, whose family name was Luciano, born in Venice in 1485, died in Rome in 1547. He studied under Giovanni Bellini and Giorgione, and by his works attracted the attention of Agostino Chigi, a merchant of Sienna, who persuaded him to visit Rome. Here Michel Angelo gave him valuable advice, and it is even reported by Vasari that he aided him in the composition of some of his most celebrated works, and set him up as a competitor to Raphael. Sebastiano's "Raising of Lazarus," which is said to include several groups and figures invented, if not designed, by the great Florentine, was at all events intended to rival the "Transfiguration" of Raphael. He excelled most however in portraiture. Clement VII. appointed him keeper of the papal seals, from which circumstance he derived his surname of Piombo (lead), the substance used in sealing bulls. His office obliged him to assume the monk's habit, whence he was styled Frate or Fra.

PIOZZI, Hester Lynch, an English authoress, born in Bodvel, Caernarvonshire, in 1739, died in Clifton, near Bristol, May 2, 1821. She was the daughter of John Salusbury, esq., and in 1764 married a wealthy brewer named Thrale. Shortly afterward she formed an acquaintance with Dr. Johnson, to which fact she owes all the celebrity she has in literature. With him she preserved a close intimacy until, much against his wishes, she married in 1784, after the death of Thrale, an Italian music master named Gabriel Piozzi. After Johnson's death she published a volume entitled "Anecdotes of Dr. Samuel Johnson during the last Twenty Years of his Life" (8vo., 1786). This publication produced a feud between her and Boswell and the other friends of Johnson, which gave rise to Dr. Wolcott's poem of "Bozzy and Piozzi." While living in Florence in 1786, she printed with Merry, Greathead, and Parsons, the founders of the Della Crusca school of poetry, a collection in prose and verse called "The Florentine Miscellany," which however was not published. Her other works are: "Letters to and from Dr. Samuel Johnson" (2 vols. 8vo., 1788); "Observations and Reflections made in the course of a Journey through France, Italy, and Germany" (2 vols. 8vo., 1789); "British Synonymy, or an Attempt at regulating the Choice of Words in Familiar Conversation" (2 vols. 8vo., 1794); and "Retrospection, or a Review of the most striking and important Events, Characters, Situations, and their Consequences, which the last Eighteen Hundred Years have presented to the view of Mankind" (2 vols. 4to., 1801). She is also said to have written much both in prose and verse for various publications; but the poems contributed in 1765 to the "Miscellanies" published by Anna Maria Williams, especially one entitled "The Three Warnings," are considered her best productions.—See "Autobiography, Letters, and Literary Remains of Mrs. Piozzi," edited, with notes and an introductory account of her life and writings, by A. Hayward (London and Boston, 1861).

PIPE, a wine measure of rather indefinite capacity. In England it is rated at 126 wine gallons, or nearly 105 imperial gallons. A pipe of Cognac brandy is about 152¼ gallons; of Montpellier, 164⅞ gallons; of Bordeaux, 99¼ gallons; of port wine, 138 gallons; of sherry, 130; of madeira, 110, &c.

PIPE, a musical wind instrument, of which there have been many varieties. It is distinguished from the flute by being blown through one end instead of the side. The ancient Egyptians possessed both the flute and the pipe, as appears from the numerous drawings representing musical performances preserved in their tombs. The pipes were made of reeds, and some of them preserved in the British museum and in the collection at Leyden are merely plain tubes, from 7 to 15 inches in length, furnished with either 3 or 4 holes, and sometimes with a small mouthpiece of reed or thick straw, compressed at the end so as to leave a very narrow aperture. Some of the pipes consist of two tubes, to be held one in each hand, one giving a deep base sound, and the other a sharp tone for the tenor. The modern Egyptians use a rude imitation of it called the double *zummara*. Wilkinson remarks: "The double like the single pipe was at first of reed, and afterward of wood and other materials; and it was introduced both on solemn and festive occasions among the Egyptians, as among the Greeks. Men, but more frequently women, performed upon it, occasionally dancing as they played; and from its repeated occurrence in the sculptures of Thebes, it was evidently preferred to the single pipe." The Romans made use of a similar instrument called the *tibia*, and a person playing the double pipe was said *canere* or *cantare tibiis*, the two tubes evidently being distinct, and not connected by one mouthpiece. The *tibia dextra*, held in the right hand, was used to lead or commence a piece of music, and was hence called *incentiva*; while the *tibia sinistra*, held in the left hand, and following the former as an accompaniment, was called *succentiva*. The former is supposed to have been the base, and the latter the tenor or treble. The Phrygian pipes, giving a grave and solemn sound, were used at funerals. Others regulated the dance, and the stroke of the oars in rowing. In the Greek mythology the pipe was the favorite instrument of Pan, to whom its invention is ascribed, and of other rural deities. The pastoral character thus early associated with it has continued to the present day, and it is now found only in remote corners of Europe, among simple and primitive people. Throughout France, England, and other European countries, it was always played in conjunction with the tabor, a small drum.

PIPE, a tube for the conveyance of water, steam, gas, heated air, or other fluid, used for a great variety of purposes in the arts and in domestic economy. The materials of which pipes are constructed are also very various. Logs of wood have been extensively used for water pipes, the sticks being bored through the centre by long augers, and fitted together by means of the conical termination at one end entering the corresponding enlarged cavity of the next length. The pipes by which London was supplied with water were not many years since thus constructed of elm wood; and similar pipes of pine are still in common use in many places in the United States. They are defective from the decay they experience when buried in the ground, which soon destroys their usefulness, and also contaminates the water that passes through them. Cast iron pipes prove a valuable substitute for wooden pipes. They can be made of any size and to bear any desired amount of pressure. They are jointed together either by projecting flanges around each end, through which screw bolts are passed, a flat ring washer of some material appropriate to the use to which the pipes are to be put being laid between the two flanges; or one of the ends of each pipe is cast with a socket large enough to admit the end of the next pipe for a short distance. The joint is then made tight by packing in hemp, and following this with melted lead, or, if it is to be exposed to heat, by sal ammoniac and iron turnings. This mixture being dampened, a rapid oxidation of the iron turnings takes place, by which they increase in bulk and become tightly set in the joint, completely filling it up. For the water works of Glasgow and Dundee the cast iron pipes have been made of late with the socket or faucet end bored out to a true taper and accurately fitted to the corresponding smaller or spigot end, which is turned in a lathe. By coating the spigot end with hydraulic cement of the consistency of paint, laid on with a brush, a tight joint is secured without the necessity of any packing; but to make this still more sure, the precaution has been adopted by Mr. James Leslie of boring out a groove around the inside of the mouth of the faucet, into which melted lead may be poured to form a ring. Both the water and new gas pipes of Dundee are bored and turned, and the process has proved perfectly satisfactory and economical. The risk to which water pipes are subject is breakage at the joints from their being undermined by excavations for sewers or other purposes. Great damage has thus been done to the water pipes at Edinburgh, which are mostly of socket joints secured with lead and yarn. In Montreal and Hamilton, Canada West, turned and bored pipes procured from Scotland have been laid for the water works, the largest size of the pipes being 18 inches diameter. Another kind of joint is formed by bringing together two ends of pipes, cast of the same diameter throughout, and shrinking upon these a collar of wrought iron. Such joinings, adding little to the diameter, are convenient for long pieces of pipe, which are to be driven down into the ground, as those used at the natural oil wells in Pennsylvania. (See PETROLEUM.) Water pipes have also been successfully made of hydraulic cement encased in thin sheet iron. (See AQUEDUCT, to which also reference may be made for an account of the different sizes of water pipes in use in the United States.) The small water pipes called service pipes are chiefly of lead, notwithstanding the serious objection of their imparting poisonous properties to the water. (See LEAD.) Various expedients have been devised for protecting the inner surface of the pipes, as by a lining of tin, of gutta percha, and of pitch, and pipes of block tin and of gutta percha have been manufactured to take their place altogether. The former, however, have proved too expensive for general use, and those of gutta percha, at least of the ordinary qualities of that article, are liable to decay.—Wrought iron pipes, such as are now used in immense quantities for steam and gas purposes, are of recent invention. In the early part of the present century, when gas was first applied to illumination, old musket barrels were sought for and fitted to screw together to serve for conveying the gas; and it was not until 1824 that processes of making wrought iron tubes were invented and patented in England. Various modes of constructing these pipes have since been introduced, differing from each other chiefly in the manner of welding together the edges of the long strip of iron, as this is turned up into the circular form. By some manufacturers a mandril was employed, upon which the edges of the pipe when lapped were beaten together; and by others the mandril was dispensed with, the scrip or "skelp" of iron being taken from the furnace almost at the point of fusion, and by the chain of a draw bench dragged through a pair of tongs with two bell-mouthed jaws, in which the edges are strongly compressed together and welded.—Copper pipes are extensively employed in distilleries of different kinds and other chemical operations, and to protect them from corrosion they are often tinned within. Brass pipes are used in situations exposed to great heat, as about steam boilers, and especially for the tubes of tubular boilers. Pipes have been made of zinc as a proposed substitute for lead, and also of an alloy of zinc and lead. Pipes for conveying gas have recently been made in France and England of bituminized paper. M. Jaloureau, a contractor for paving Paris and other towns in France with bituminous concrete, noticing the stiffness and solidity of a roll of paper that had been left some time coated with bitumen, was led to prepare some pipes in this manner, which proved so strong and impervious, that experiments were made with them by direction of the municipal authorities of Paris to test their durability as gas pipes buried in the earth; and at the end of 12 months, on being taken from the ground, it is said they appeared like new pipes. A piece of the pipe, of 2 inches diameter of bore and ½ inch thickness of material, supported upon bearings 3 feet apart, was broken only by a weight of 428 lbs.; and specimens of only ¼ inch thickness were found capable of resisting a pressure of 250 lbs. to the square inch. Pipes cut out of solid blocks of stone were in use to some extent in London in the early part of the present century, and several ingenious modes of preparing them were contrived. By one method circular cutters were made, the first one to remove a central core from the block, and larger ones followed, each removing a hollow cylinder of its own diameter. The pipes, though good in other respects, were costly and liable to be broken in the joints by the jarring occasioned by carriages passing over them. Baked earthenware pipes are now prepared for the conveyance of water, and especially for drains. (See DRAINAGE.)

PIPE, TOBACCO, a bowl and connecting tube made of baked clay, stone, or other material, and used in smoking tobacco. Clay pipes, with slender stems of 6 inches to a foot or more in length, have been largely supplied to commerce from potteries devoted to this manufacture in London and other places in England, the clay, which is a peculiarly white and adhesive variety, being obtained from Purbeck in Dorsetshire. The brittle character of the pipes is in part compensated for by their cheapness; and though they are now giving place to more durable kinds made of other clays, of porcelain, and even of wood, the consumption of the old-fashioned clay pipes is still large among the laboring classes in all parts of the United States, as well as in other countries. But many earthenware pipe bowls are now made without the stem, some of plain form, and some with grotesque heads and figures of a great variety of shapes. These are used with a stem of cane or other wood, which any one can fit to them. Upon the American continent pipes have been in use from very remote periods. They are found in the ancient mounds of the West together with other relics of an unknown race, elaborately carved in stone into fanciful shapes, often resembling various animals of the country. In northern New York and in Cayuga co. they are frequently discovered in ploughing the land. Some are of soapstone and others of baked clay. In the account of the discovery of the Hudson river by Robert Juet, mention is made of "red copper tobacco pipes and other things of copper, which the savages did wear about their necks." In the N. W. territory, upon the summit of the dividing ridge between the St. Peter's and the Missouri rivers, called the Coteau des Prairies, and in the latitude of St. Anthony's falls, the Indians have long procured a peculiar variety of red steatite or soapstone, of which all the red stone pipes of that region are made. The locality is held in great reverence by the Indians, and they have strongly opposed any attempts of the whites to visit it. Catlin, however, succeeded in overcoming their scruples, and was shown the spot at the base of a long vertical wall of quartz, which lay in horizontal strata, the pipestone layers spreading under the adjoining prairie land of the ridge, whence it was obtained by digging a few feet in depth. He judged from the great extent of the excavations, and from the graves and ancient fortifications, that the place must have been frequented by different tribes of Indians for many centuries. ("American Journal of Science," vol. xxxviii., 1840.) The pipes made of this stone are heavy, and usually of rather plain form, decorated by bands and ornaments of lead, which appear to have been run into depressions made to receive it and then smoothed down. The stems are long and curiously carved sticks of hard wood, sometimes flat, frequently ornamented with gaily colored feathers of birds and horse hair dyed of scarlet hue. The most elaborate pipes are those of the Asiatics, especially the Persians and Turks. (See MEERSCHAUM.) The bowls are large and heavy, not intended to be held in the hand or carried about, and the stems are several feet long, sometimes made in part of spiral wire covered with a thin impervious coating of leather or other substance, so that this portion of them is very flexible. The mouthpiece is of ivory, silver, or amber, the last being preferred and much the most expensive. The principal portion of the amber product of Prussia is applied to this use, and some of the mouthpieces command very large prices. In the Turkish department of the great exhibition of 1851 there were 4 amber mouthpieces valued together at £1,000. The eastern *hookah* or *houkar* is a pipe of extraordinary size, and an instrument of such importance in the courts of the princes that an officer called the *houkar bourdar* is specially appointed to take care of it, and present the mouthpiece to his master for smoking. The large bowl of this pipe is set upon an air-tight vessel containing water, and a small tube from the pipe passes down into the water. The smoking tube is inserted into the side of this vessel, and communicates through a long flexible tube with the mouthpiece. By exhausting the air through this the smoke is forced down under the water, and entering the space above it passes into the stem freed by its contact with the water from some of the most acrid properties of the tobacco. The German pipes are of great variety, as well of material as of form. Those of porcelain are sometimes beautifully painted in the style of fine chinaware painting. Other pipes are of wood and of meerschaum, with long and with short stems.

PIPE CLAY. See CLAY, vol. v. p. 205.

PIPE FISH, the popular name of the subfamily *syngnathinæ* of the lophobranchiate order of marine acanthopterygious fishes, and particularly of the genus *syngnathus* (Linn.). The characters of the order have been given in the article LOPHOBRANCHS. In the subfamily the form is much elongated, and covered with a series of imbricated plates, and the gills are arranged in tufts instead of plates. The genus has a 7-sided body, the snout straight and cylindrical, and without spines; a single dorsal on the middle of the back, not on an elevated plane, the upper border of the back never in the same line with that of the tail; the upper border of the latter either continuous with the lateral line or interrupted where that ends; dorsal surface flat or slightly concave, and the rings of the body 24 to 27; the gill opening is circular and high up, and the ventrals are wanting; the jaws tubular, the mouth at the end; in some species the pectorals, anal, and caudal are wanting; the tail is not prehensile; the head in the same line with the body; the males have a caudal egg pouch under the tail, open in its whole extent. About 20 species are described, of which in Europe the best known is the great pipe fish (*S. acus*, Linn.), sometimes called needle fish; this has all the fins except the ventrals; it is found at low or high water, swimming slowly among sea weeds, feeding on small crustaceans and mollusks, marine worms, insects, and roe of fishes. In the male the posterior part of the abdomen is broader than the rest, with 2 soft flaps folding together and forming a kind of pouch for the reception of the eggs, which, it is believed, are placed there by the female; it is greatly attached to the young, which also, when small, are said to take refuge in the pouch; it is interesting to observe that whenever among fishes unusual care is taken of the eggs or young, this duty is performed by the males, while in other classes the females, assisted occasionally by their mates, protect and feed the young. It attains an average length of 18 inches, and is pale brown, transversely barred with darker brown; the tail is fan-shaped. Another species of the English coast is the *S. typhle* (Linn.), characterized by its deeper jaws; it is about 13 inches long, olive green, mottled and spotted with yellowish brown and white. Among the species which have no fins but the dorsal, and no subcaudal pouch, are the *S. æquoreus* (Linn.) of the British seas, about 20 inches long, of a yellowish color, with transverse pale lines and dark margins; the snake pipe fish (*S. ophidion*, Linn.), about 14 inches long, of the size of a goose quill, the tail ending in a point, and the color a uniform olive green; and the worm pipe fish (*S. lumbriciformis*, Jen.), only 5 or 6 inches long, of a dark olive green color. In America is the *S. Peckianus* (Storer), which attains a length of 12 inches; the color is olive brown, with numerous transverse darker bars, and yellowish below; pouch present, and all the fins except the anal, or the latter is exceedingly minute; eyes prominent and very movable. Another species, from New England and New York, less common, is the brown pipe fish (*S. fuscus*, Storer), of a general brownish color. It is very easy to see in the aquarium that the tail is not the sole nor the principal organ of locomotion in these fishes, and many species have no fin but the dorsal; when desirous of rapid progress, they move the body very much like an eel, but in ordinary locomotion the dorsal is the chief motor organ; this may be seen to make short and quick vibratory movements which pass in spiral waves along its border, like the screw of a propeller, and might well have suggested this motive power to naval architects. They have also a remarkable power of moving the eyes, even through an arc of 90°, and each independently of the other; this faculty is possessed by the family.—Other acanthopterous species of the family *aulostomidæ* are also called pipe fishes; these are characterized by the prolongation of the bones of the face into a long tube, at the end of which is the mouth; the ribs are short or absent, and the intestines have neither great dilatations nor many folds. In *fistularia* (Linn.) the mouth is small, with a nearly horizontal gape; the body long and slender, the head forming ⅓ or ¼ of the total length; branchiostegal rays 6 or 7; dorsal single and simple, opposite the anal; teeth small; one or two jointed filaments, sometimes as long as the body, issuing from between the deep forks of the caudal; air bladder very small; scales invisible. The serrated pipe fish (*F. serrata*, Bloch) attains a length of 28 to 30 inches, of which the caudal filament is 10 or 12; color light drab, with a narrow brownish blue band along the sides, the throat white, and the abdomen and irides silvery;

the snout with longitudinal serrated ridges; the lower jaw the longer and somewhat curved upward, with a fleshy protuberance at the chin; the shoulders covered with horny plates; the dorsal and anal triangular, pectorals quadrangular, ventrals very small and about midway between pectorals and anal; it is found from Massachusetts to the coast of Brazil. The tobacco pipe fish (*F. tabacaria*, Bloch), also American, is smaller, brownish with a row of pale spots, with the abdomen white in the middle, and the orbits spiny. In *aulostoma* (Lacép.) the dorsal is preceded by some free spines, the jaws toothless, the facial tube and body less slender, the latter scaly, the tail without filament, and the air bladder very large; the *A. Sinense* (Bloch) inhabits the Indian ocean. In *centriscus* (Linn.) there is the tubular snout, but the body is oval and compressed, trenchant on the abdomen; there is a spinous dorsal very far back, with a strong 1st spine, and a soft dorsal behind it; the body is covered with small scales. The *C. scolopax* (Linn.), called sea snipe and trumpet fish, is common in the Mediterranean; it is 4 or 5 inches long, reddish on the back and sides, and silvery on the belly, sometimes with a golden tinge; its flesh is delicate and esteemed. In *amphisile* (Klein) the back is cuirassed by broad scaly plates, and the strong dorsal spine is continued backward in the axis of the body, of which it actually forms the hinder extremity, the second dorsal and the anal being crowded backward and even on to the under surface; they are from the Indian ocean. The food of all these fishes consists of minute crustaceans and other marine animals, which they detach from various kinds of sea weed.

PIPPI. See Giulio Romano.

PIQUA, a city of Miami co., O., on the Great Miami river; pop. in 1860, 4,620. It is at the junction of the Dayton and Michigan and the Columbus and Indianapolis railroads, 72 m. W. from Columbus, and 88 m. N. from Cincinnati, with which and Toledo it is also connected by the Miami canal. The city is regularly laid out with wide streets, and 2 bridges connect it with Rossville and Huntersville, on the opposite side of the river. Water power is supplied by the waste of the canal, and there are numerous manufactories. The city contains a bank, a town hall, 3 newspaper offices, and 12 churches.

PIQUET, a game of cards played by two persons. The name is French, and refers to a phrase in the game, the *pique*, which has its equivalent in the English "point." The game is 100. The denominations of the score are the following: 1. *Carte blanche*, which is when a hand dealt contains no face card. This hand enables the holder to count 10, and is counted before any other. 2. Point, which is reckoned by the player who has the greater number of cards in any one suit, or, if both have an equal number, by the one who has the greater number of pips. In this count the face cards stand for 10, and the ace for 11. Whoever has point counts one for each card he holds. 3. Sequence, which is several cards in the same suit, following consecutively, counts 3, 4, 15, 16, 17, or 18, according as there are 3, 4, 5, 6, 7, or 8 consecutive cards. 4. The *quatorze*, which is 4 cards of equal value in 4 different suits, counts 14. 5. The cards are reckoned by the winner of the greater number of tricks, and count 10. 6. The *capot*, counted by a player who wins all the tricks, makes 30 toward the game, beside 10 reckoned for the cards. There are many similar implications in piquet, especially in the sequence, where the holder of the greater sequence, a *huitième*, or 8, is entitled to count for the *huitième*, and for every lesser sequence that it involves—a *tierce*, a *quart*, a *quint*, a *seizième*, and a *septième*—that is, 73. From an ordinary pack of cards the 2, 3, 4, 5, and 6 are discarded for piquet, and the other cards rank as at whist. The cards are dealt 2 by 2, until each player has 12, and the *talon* or stock is then placed upon the board. From this the elder hand has the right to draw 5 cards in their natural order, and must then discard the same number from his own hand. This discard affords him some opportunity to arrange his hand with reference to the various scores. It is imperative upon the elder hand to discard at least one card, but not the whole 5. If he discards less than 5 he has the privilege of looking at the cards left. His own discard is optional with the dealer, and if chosen follows after every other hand. Tricks are taken in the usual manner by the superior cards of the same suit.

PIR PANJAL, or the Saints' Mountain, a lofty range, forming part of the S. W. boundary of Cashmere, and separating it from the Punjaub. Its highest point, in or near lat. 33° 40' N., is about 15,000 feet above the sea. At the S. W. extremity is the pass of the same name, about 12,000 feet high, but below the limit of perpetual snow.—Pir Panjal is also the name of a river which rises in this range, and falls into the Jhylum in lat. 33° 16', long. 73° 38' E.

PIRACY, robbery upon the sea. Spelman says that *pirata* once meant in England sea knight or soldier; and he cites an instrument of the time of King Edgar, in which one of the witnesses styles himself *archipiratam*, that is, as Spelman translates it, admiral. He also quotes Asser and another ancient chronicler, who write that the war galleys of Alfred and of William the Conqueror were manned by *piratæ*. The legal definitions of pirate and piracy are derived from the civil law, whence they were transferred to the maritime and admiralty laws and the law of nations. The civil law applied *piratæ*, *prædones*, and *latrones* to the same kind of offenders; indeed, the latter terms were sometimes used interchangeably with the former. But the proper, and in fact the sole difference between the terms was that *prædones* and *latrones* described robbers upon land, while *piratæ* meant robbers on the sea.

The writers upon the civil, the international, and maritime codes agree in defining piracy as robbery or depredation on the sea. Strictly speaking, piracy is not an offence known to the common law. As it is a crime committed on the high seas, it is committed out of its jurisdiction. As Sir Charles Hedges said in the high court of admiralty in 1696: "Piracy is the sea term for a robbery committed within the jurisdiction of the admiralty." Until the statute 28 Henry VIII. it was exclusively a civil law offence, cognizable only by the admiralty courts. But the procedure under the forms and rules of the civil law includes no trial by jury, and it was plainly an encroachment on the liberties of the English subject that his life should be forfeited without judgment by his peers, according to the law of the land. Furthermore, as the statute itself recites, there could be under the civil law no conviction for a crime unless the accused plainly confessed it, or it were directly proved by witnesses who saw it committed. The statute therefore enacted that the offences which it contemplates should be judged in such shires and places as should be designated by the king's commission, and in the same form as if the alleged crime had been committed upon the land. This commission is directed to the admiral or his deputy, and to three or four others, among whom, says Blackstone, are usually two common law judges. The indictment is found and tried by grand and petit jury, and the trial follows, in other respects, the course of the common law. Yet it is to be observed that the court thus constituted is still essentially an admiralty court. The statute, said Chief Justice Mansfield, merely altered the mode of trial, but the jurisdiction of the court rests on the same foundation as before the act; it is regulated by the civil law and by maritime customs, grounded on the law of nations. Piracy, therefore, can be said to be an offence at common law only when this term is taken in its most comprehensive sense, and so inclusive of the law of nations.—In the United States, the cognizance of piracy is reserved by the constitution to the general government. The 8th section of the 1st article of that instrument gives to congress the power "to define and punish piracies and felonies committed on the high seas, and offences against the law of nations." Under this constitutional provision, and because the U. S. courts have no common law jurisdiction, the definition of piracy in our law is to be sought exclusively in the acts of congress, and it will be seen that they have materially enlarged the usual conception of the offence. Of the acts by which congress has exercised the authority conferred by the constitution, the earliest was that of April 30, 1790. It declared that murder or robbery committed on the high seas, or in any river, haven, or bay out of the jurisdiction of any particular state, or any other offence which, if committed within the body of a county, would by the laws of the United States be punishable with death, should be adjudged to be piracy; and if any captain or mariner should piratically and feloniously run away with any vessel, or any goods of the value of $50, or yield up any such vessel voluntarily to pirates, or if any seaman should by force attempt to hinder his commander from defending the ship or goods committed to his trust, every such offender should be adjudged a pirate and a felon, and be punishable with death. The terms murder and robbery in this act are to be understood as they are defined at common law. The words high seas apply to any waters near sea coasts which are beyond low water mark. The next act touching piracy was that of March 3, 1819, which was extended for two years by the act of May 15, 1820. After this period had elapsed, the act of Jan. 30, 1823, revived without limitation the first 4 sections of the act of 1819. These sections contained provisions authorizing public and private ships to seize pirates wherever they might be found. They are still in force. The 5th section of the act of 1819 was directed against those who should commit "piracy as defined by the law of nations;" and so long as it remained upon the statute book it conferred upon the U. S. courts a jurisdiction over piracy quite the same as that which is exercised over the offence in England. This section was not continued by the act of 1823, but seems to have been displaced by the 3d section of the intermediate statute of 1820. Indeed, Chancellor Kent says that this section is substantially a definition of piracy according to the law of nations. It runs as follows: "If any person shall upon the high seas, or in any open roadstead, or in any haven, basin, or bay, or in any river where the sea ebbs and flows, commit the crime of robbery in or upon any ship or vessel, or upon the lading thereof, or upon the crew, he shall be adjudged a pirate. . . . . If any person engaged in any piratical enterprise, or belonging to the crew of any piratical vessel, shall land and commit robbery on shore, such person shall also be adjudged a pirate, and upon conviction shall suffer death." The act of March 3, 1847, provides that subjects or citizens of foreign states found and taken on the seas making war on the United States, or cruising against the vessels and property thereof, or of the citizens of the same, contrary to the provisions of any treaty existing between the United States and the country of such persons, shall, when such acts are declared by such treaties to be piracy, be arraigned, tried, convicted, and punished in the courts of the United States. Finally, citizens of the United States who are engaged in the slave trade are declared by the statute of 1820 to be pirates, and upon conviction are to suffer death.—These are the existing laws concerning piracy. A review of the chief points which have been made in construction of them will present conveniently the American law of this offence. We have seen that, though the section which expressly gave jurisdiction over "piracy as defined by the law of nations" was limited in its duration, yet a subsequent act contained provisions which were substantially declaratory of the international law in this respect. It is also to be observed, that the still operative sections of the act of 1819, which provide for the seizure of those who shall have attempted or committed any piratical aggression, search, restraint, or depredation, necessarily require construction according to the law of nations. Thus, in commenting on this word piratical, Judge Story said that the statute intended by it all acts or offences which pirates are in the habit of perpetrating; and that, in the case before him, the wilful sinking and destroying of an innocent merchant ship, without any other object than to gratify a lawless appetite for mischief, was a piratical aggression, in the sense of the law of nations, and of the act of congress, just as much as if the act had been done for the purposes of plunder. The act of 1790 declares every offence committed at sea to be piracy, which would be punishable with death if committed on land. This statute, says Chancellor Kent, may be considered as enlarging the definition so as to include not only every offence which is piracy by the law of nations and the act of congress of 1819, but also other offences which were not piracy until made so by statute. The act of 1820, which declares slave traders pirates, can apply only where the municipal jurisdiction of the United States extends, and must be limited to American citizens or to foreigners on board of American ships. It has been repeatedly decided that the slave trade is not an offence under the law of nations; nor is it piracy except when it is made so by statute or treaty. Under these acts, the United States courts take jurisdiction of those offences alone which are committed by or upon citizens of the United States, or over those which, though not committed upon American citizens, are yet committed by those who acknowledge no national authority, but are the common enemies of all nations, and may therefore be justly punished by any. Our courts assume no jurisdiction over those who are under the acknowledged authority of a foreign state.—The general rule, that robbery on the high seas is piracy, has no exception or qualification in favor of commissioned privateers in any act of congress, or in the law of nations; and accordingly a privateer bearing a commission of the United States, who feloniously seized the goods of a neutral, that is to say, robbed him on the high seas, was adjudged a pirate.

PIRÆUS, the port of Athens, situated about 5 m. S. W. from the city, on a peninsula of the same name. It has 3 harbors, 2 on the E. side, anciently called Munychia (now Phanari) and Zea (now Stratiotiki), and one large one on the W. side, called simply Piræus or the Harbor. The last was anciently divided into two parts, the one on the right, called Cantharus, being appropriated to ships of war, and the one on the left, called Emporium, being used for merchant vessels. Previous to the Persian war Phalerum had been the port of Athens, but Themistocles, seeing the natural advantages of the Piræus, surrounded the peninsula with a line of fortifications 60 stadia in circumference and 60 feet high. The northern of the two long walls connecting Piræus with the city was begun by the advice of Pericles in 457 B. C. and finished in 456, and the southern, called the intermediate, was built between 456 and 431. They were destroyed by the Lacedæmonians at the end of the Peloponnesian war, but after the naval victory of Cnidus were rebuilt by Conon, and in later times fell into decay. Piræus was taken by Sylla, and never recovered from the blow inflicted upon it by that general, who destroyed its fortifications and arsenals. It had become even in the time of Strabo an insignificant village. The modern town has sprung up entirely since 1834, and in 1852 its population was 5,526. It contains 4 churches, 6 schools, a custom house, and a lazaretto. The harbor of Piræus was called during the middle ages Drako or Porto Leone, but it has now recovered its original name. It is deep and safe, though the entrance is somewhat difficult. The number of vessels belonging to the port in 1855 was 496, and the value of the imports in that year was $1,350,000.

PIRANESI, Giovanni Battista, an Italian engraver, designer, and architect, born in Venice in 1720, died in Rome, Nov. 9, 1778. He studied architecture in Rome, where he resided more than 40 years, devoting himself principally to the production of engravings of architectural subjects and ancient ruins. Among the most important are the *Antichita Romana* (208 plates, 4 vols. atlas folio, 1756); the *Antichita d'Albano* (35 plates, 1764–'5); *Magnificenza dei Romani* (44 plates, 1761); *Vedute di Roma* (2 vols., 130 plates of modern buildings in Rome); the *Campus Martius* (54 plates, 1762); *Statue antiche* (1781–'4), a collection of 850 subjects; "Antiquities of Herculaneum and Pompeii," &c. Piranesi drew at once on the plate, and finished it by etching, hardly using the graver. For spirit and vigor of execution and bold effect his works are unique in art. A complete set of them, comprising nearly 2,000 subjects in 30 folio volumes, was published in Paris by his son Francesco in the early part of the 19th century. The plates are now in the possession of the Roman government, and are deposited in the Vatican.

PIRATE. See Piracy.

PIRON, Alexis, a French wit and dramatist, born in Dijon, July 9, 1689, died Jan. 23, 1773. He was the son of an apothecary who was celebrated in his province for his *noëls* or satirical songs. Alexis studied law, but, unable to follow the profession on account of his father's reduced circumstances, he earned a scanty living as a copyist, and at the age of 30 removed to Paris, where he was engaged to write light comedies for the *théâtre de la foire*. His first play produced there, *Arlequin Deuca-*

lion, which he wrote in about 2 days, was a decided success, and he followed the profession of a light dramatist until he was encouraged to attempt a higher flight by his friend Crébillon. His first 5-act comedy, *Les fils ingrats, ou l'école des pères*, was performed in 1728 at the French theatre, with moderate applause. Of two tragedies which he afterward produced, one failed and the other succeeded. Two comedies, now forgotten, followed; and finally in 1739 *La métromanie, ou le poëte*, his masterpiece and one of the best plays in French literature, appeared. In 1741 he produced *Fernand Cortez*, a tragedy, which failed. In concert with Collé, Panard, and others, he established the singing society known as *le caveau*, and gave much of his time to convivial pleasures. His wit and readiness at repartee were almost proverbial, and Voltaire himself was careful not to quarrel with him. The French academy, which had been frequently the object of his satire, nevertheless elected him a member in 1753; but the king refused his assent, on account of a licentious poem composed by Piron in his youth, whereupon he wrote his own epitaph: "Here lies Piron, who was nothing, not even an academician!" His works have been published at Paris in 7 vols. 8vo. (1776).

PISA, an ancient city of Peloponnesus, and the capital of the middle district of Elis called Pisatis, situated in the lower valley of the Alpheus, between Harpina and Olympia, a short distance E. from the latter. It was first celebrated as the residence of Pelops, after which it appears to have declined. Subsequently it became the head of a confederacy of 8 states, and had the presidency of the Olympic festival, of which it was deprived by the neighboring Eleans, recovering it however in the 34th Olympiad, 644 B. C. This privilege thenceforth became a continual cause of war between Pisa and the various rulers of Elis, until in the 52d Olympiad the Eleans were finally successful, and Pisa was razed to the ground. So complete was its destruction, that even its existence was disputed in the time of Strabo.

PISA, a city of Italy, and capital of a prefecture of the same name in Tuscany, situated upon both sides of the Arno, about 7 m. from its mouth, 13 m. N. N. E. from Leghorn, and 50 m. W. from Florence; pop. in 1858, 23,000. It has communication by railway with Leghorn, Lucca, and Florence. It is built on a marshy fertile plain, enclosed on the E. by the Apennines, and open on the W. to that part of the Mediterranean which is called the Tuscan sea. It is surrounded by an ancient wall a little more than 5 m. in extent, with 5 gates. The circuit of the wall enclosed originally much garden ground, and the unoccupied space has been increased by the destruction of many convents, giving the outer parts of the city a desolate appearance. The Arno, here a muddy stream, forms almost a semicircle within the walls. It is lined upon both sides with stone quays, and spanned by 3 bridges. The Ponte alla Fortezza, in the E., has 4 arches. Next below it is the Ponte del Mezzo, or middle bridge, with 3 arches; it is built of marble, and is esteemed the finest bridge in Europe. The Ponte à Mare is the westernmost; it has 5 arches, was built in 1331, and restored a century later by Brunelleschi. The long wide streets upon either side of the Arno, called Lung' Arno, are gay and cheerful. The Palazzo Uppizzinghi is said to have been designed by Michel Angelo, as also its neighbor the Palazzo Lanfranchi. Among the interesting edifices on the S. side of the river are the Loggie di Banchi, erected in 1605, and now used for a corn market; and the academy of fine arts, founded by Napoleon in 1812. In a large grass-grown square at the extreme northern angle of the city stand four of the most remarkable structures in the world, all built of white marble in corresponding style: the cathedral, with its baptistery, its *campanile* or belfry (the celebrated leaning tower), and the Campo Santo or cemetery. The cathedral was erected to celebrate a triumph of the Pisans in the harbor of Palermo in 1063, when allied with the Normans to drive the Saracens out of Sicily. It was begun in 1064 and finished in 1118, is in the form of a Latin cross, 311 feet long and 106 feet wide in the interior, and is richly ornamented with ancient stained glass, paintings, and statuary, including masterpieces by Beccafumi, Andrea del Sarto, Staggi, Nicola Pisano, and others. There are 12 altars in the nave and transepts said to have been designed by Michel Angelo. It was greatly injured by a fire in 1596, and its foundations have settled so that every part of the original structure is out of line. The baptistery, commenced in 1152, but probably not finished till the 14th century, is a circular building 100 feet in diameter and 179 feet in extreme height, and has fine mosaic pavements, elaborately carved columns, and numerous bass-reliefs. The campanile was begun in 1174. It is 190 feet high, and consists of two concentric circular walls, each 2 feet thick, with a stairway running up between them. The well inside the inner wall is 2 feet in diameter. The tower is divided into 8 stories, each having an outside gallery of 7 feet projection, and the topmost story overhanging the base about 15 feet, though, as the centre of gravity is still 10 feet within the base, the building is perfectly safe. It has been supposed that this inclination was intentional; but the opinion that the foundation has sunk is no doubt correct. It is most likely that the defective foundation became perceptible before the tower had reached one half its height, as at that elevation the unequal length of the columns exhibits an endeavor to restore the perpendicular, and at about the same place the walls are strengthened with iron bars. The Campo Santo, the archetype of all similar cemeteries in Italy, is a structure 415½ feet long and 137 feet 10 inches wide, commenced in 1278, and enclosing a mound of earth brought from Mt. Calvary many years before by Archbishop Ubaldo when expelled from Palestine by Saladin. It contains a rich collection of monuments, including many Roman sarcophagi, and the walls are covered with ancient frescoes. The university of Pisa is among the most celebrated in Italy. Its degrees, except in divinity and canon law, are accessible to persons of all creeds. Galileo was one of its professors. Its library contains 55,000 volumes. Pisa is supplied with water conveyed from the Valle d'Asciano by an aqueduct, begun in 1613, of 1,000 arches and 4 m. long, and having 8 reservoirs. Soap, glass, and vitriol are made to some extent, but Pisa has little importance either as a manufacturing or commercial city.—Pisa was an ancient city of Etruria, and its origin, through the identity of name, has been ascribed, no doubt incorrectly, to a colony from the Peloponnesian city. It is first mentioned as a dependency of Rome in 225 B. C. In the 10th century it was the first among the commercial republics of Italy. In the 13th century a struggle with Genoa began, which ended disastrously for Pisa. It took part in the contests of the Guelphs and Ghibellines, in which Count Ugolino with two of his sons and two grandsons were imprisoned in a tower in Pisa and starved to death. It was taken by the French in 1799.

PISANO, the name applied to several artists of Pisa distinguished at the period of the revival of the arts in Italy. I. Giunta, commonly called Giunta di Pisa, born probably in 1180 or 1190, died about 1250. He is the earliest Tuscan painter of whom there is any record, having been many years anterior to Cimabue, and probably acquired a knowledge of his art from the Byzantine painters who settled in Pisa after the capture of Constantinople by the Venetians. II. Nicola, the greatest artist of the 13th century, born about 1200, died about 1275. He was one of the most eminent of the restorers of sculpture, and among the earliest to return to the study of the antique. As an architect he was almost equally distinguished, and his works in Florence, Naples, Pisa, Venice, and other Italian cities were numerous and splendid. He was the first original artist of the renaissance, and gave the first impulse to the movement, successfully carried out by Giotto and his school, for the rejection of the Byzantine types of art and the adoption of those founded on nature. III. Giovanni, son and pupil of the preceding, born about 1235, died in 1320. His chief work is the Campo Santo or cemetery of Pisa. As a sculptor he was a worthy successor of his father, and became celebrated throughout Italy. IV. Andrea, a sculptor and architect, distinguished as a metal founder, born about 1280, died in Florence in 1345. He executed works in sculpture for various churches of Florence, but is best known by his bronze gates for the baptistery of St. John in that city. As an architect he designed several churches in Tuscany, and according to Vasari the arsenal at Venice.

PISCATAQUA, a river flowing between New Hampshire and Maine. It rises in East pond between the towns of Wakefield, N. H., and Newfield, Me.; thence to Berwick Lower falls it is called Salmon Falls river, after which until its junction with the Cocheco it is known as the Newichawannoc; thence to the ocean, which it enters about 3 m. below Portsmouth, it has the name Piscataqua. The harbor, from Portsmouth to the sea, owing to the strong tides, is not much obstructed by ice, and is one of the best in the United States.

PISCATAQUIS, a N. co. of Me., drained by the Piscataquis and the west branch of the Penobscot and their tributaries; area, 3,750 sq. m.; pop. in 1860, 15,032. Its surface is dotted over with hills, the highest of which is Mount Katahdin, and contains a large number of lakes, of which the principal are Sebec, Pemadumcook, Carribou, Chesuncook, and Moosehead; the last named is the largest, and is 35 m. long by from 4 to 12 wide. A large portion of the land is yet unsettled. The productions in 1850 were 14,646 bushels of wheat, 48,925 of Indian corn, 147,034 of potatoes, 171,220 of oats, 21,746 tons of hay, 54,334 lbs. of wool, and 349,576 of butter. There were 3 grist mills, 20 saw mills, 1 woollen and 2 flannel factories, 25 churches, and 6,055 pupils attending public schools. Capital, Dover.

PISCICULTURE. See Fishes, vol. vii. p. 535.

PISE, Charles Constantine, D.D., an American clergyman and author, born in Annapolis, Md., in 1802. His father was an Italian of an ancient noble family, his mother a native of Philadelphia. He was educated in the Roman Catholic faith, and after graduating at Georgetown college under the care of the Jesuits went to Rome to study theology. After about 2 years' absence he was obliged to return home in consequence of the death of his father. He then entered the seminary of Mount St. Mary's, Emmittsburg, where he taught rhetoric and poetry, and finished his theological studies under Dr. Bruté, afterward bishop of Vincennes. Ordained priest by the archbishop of Baltimore in 1825, he began his pastoral duties at Frederictown, Md., and about 6 months afterward was called to the cathedral at Baltimore, where he wrote his "History of the Church from its Establishment to the Reformation" (5 vols. 8vo., Baltimore, 1830); "Father Rowland," a tale, in answer to "Father Clement;" and "The Pleasures of Religion, and other Poems." His health failing, he again visited Rome, where he received the degree of D.D., and the honorary title of knight of the Roman empire. After his return to the United States he was associated with the Rev. Mr. Matthews in the pastorship of St. Patrick's church, Washington, and through the influence of Henry Clay, who became his warm personal friend, was appointed chaplain of the U. S. senate. Mr. Clay also offered him the chair of rhetoric in Transylvania university, which he declined. At the invitation of Dr. Dubois, bishop of New York, he removed to the latter city, and was settled over several churches successively, the last being St. Peter's in Barclay street. During a journey to Ireland on business connected with the church he sketched the scenery of the country and the manners of the people in his "Horæ Vagabundæ." In 1849 he resigned his position at St. Peter's, purchased the Emmanuel church in Brooklyn, and dedicated it to Catholic worship under the patronage of St. Charles Borromeo. Of this he is still pastor. In 1858 he delivered a Latin ode at Emmittsburg on occasion of the 50th anniversary of the foundation of Mount St. Mary's college. Dr. Pise is one of the most prominent Catholic clergymen in America, both as a lecturer and preacher. Beside numerous fugitive pieces and translations of the hymns of the breviary, he has written a poem entitled "The Acts of the Apostles;" "Zenosius, or the Pilgrim Convert;" "Indian Cottage, an Unitarian Story;" "Aletheia, or Letters on the Truth of the Catholic Doctrines;" "Letters to Ada;" "Christianity and the Church;" "Lives of St. Ignatius and his first Companions;" "Notes on a Protestant Catechism, &c.;" and "The Catholic Bride," translated from the Italian. He has nearly ready for the press an epic poem in 4 cantos.

PISIDIA, in ancient geography, a province in Asia Minor, bounded N. by Phrygia Paroreos, E. by Isauria and Cilicia, S. by Pamphylia, and W. by Lycia, Caria, and Phrygia. It became a separate province on the division of the Roman empire by Constantine the Great, having previously been included either under Phrygia or Pamphylia. Olives, salt, iris, a root from which perfumes were manufactured, and the wine of Amblada, highly prized by the ancient physicians, were produced. The chief towns were Antiochia, Sagalassus, and Selge, the last mentioned being the most important. The inhabitants were mountaineers, never conquered either by the Syrian kings or by the Romans, although the latter held possession of some of their chief towns. In the time of Strabo they were ruled over by petty chiefs, and derived their subsistence mainly from plundering their neighbors. The mountainous parts of the ancient Pisidia are now inhabited by Caramanians, a wild predatory people. The country is rarely visited and little known.

PISISTRATUS, tyrant of Athens, born about 612 B. C., died in 527. He traced his descent to the Homeric Nestor and the Pylian kings. Distinguished for mental and physical endowments, he became the friend of his kinsman Solon, and accompanied him in the expedition for the recovery of Salamis. After the adoption of the constitution of Solon, Athens was divided into 3 parties: the proprietors of the plain, headed by Lycurgus; the party of the coast, headed by Megacles, the son of Alcmæon; and the party of the highlands, consisting of the poorer classes, headed by Pisistratus. Having wounded himself, Pisistratus appeared one day in the agora, complaining that he had been attacked, and asking for a guard. A company of 50 club-men was assigned him, which soon being increased, he seized the acropolis, and compelled his leading opponents to flee. Strenuous resistance was made by Solon, who however was unable to effect any thing, and appears not to have been molested. The seizure of the citadel took place in 560; but the chronology of the ensuing events is confused. Pisistratus did not long enjoy his elevation. A coalition of his opponents was formed, and he was driven from the city; but dissensions arose among them, and overtures were made to Pisistratus by Megacles, who offered him the sovereignty on condition that he should marry his daughter. This was agreed to, and Pisistratus entered Athens in a chariot by the side of a stately woman named Phya, clothed in the costume of the goddess Athena, heralds going before and crying out: "Athenians, cordially receive Pisistratus, whom Athena has honored above all other men, and is now bringing back into her own acropolis." He thus gained possession of the government, and married the daughter of Megacles; but not choosing to have children by a member of a family deemed to be accursed, he so incensed the Alcmæonids that they again united with the party of Lycurgus, and expelled him. Retiring to Eretria in Eubœa, he spent the 10 years of his exile in making preparations for his return, and at the expiration of that time landed at Marathon with mercenaries and troops led by Lygdamis of Naxos, and succeeded in reëstablishing himself in power. He now took into pay a body of Thracian troops, exiled the Alcmæonids, and kept the children of many of the principal citizens as hostages. His reign, however, seems to have been mild, and received the commendation of Herodotus, Thucydides, and Aristotle. But the last named imputes to him the design of impoverishing as well as employing his subjects by undertaking great works. This view is supported by the scale upon which the temple of the Olympian Jupiter was planned, and which remained unfinished until the time of Hadrian. Among other acts he purified the island of Delos by removing the dead bodies buried within sight of the temple. He is also said to have instituted the greater Panathenaic festival. Under his encouragement the earliest form of tragedy appears to have been brought into Athens, and the poems of Homer were collected and written down. He also made a collection of other works, which Aulus Gellius calls a library. He conquered Naxos, placing Lygdamis upon the throne, and wrested Sigeum from the Mitylenæans. He was succeeded by his sons. (See HIPPARCHUS AND HIPPIAS.)

PISSELEU, ANNE DE. See ÉTAMPES, DUCHESS D'.

PISTACHIO (*pistacia vera*, Linn.), a small tree indigenous to Syria, growing 20 feet high, with deciduous, unequal, pinnate leaves of 3 to 5 leaflets; diœcious, apetalous flowers, arranged in short branching racemes from the old wood; the fruit a drupe of a reddish color, with a thin rind and a brittle 2-valved shell containing an almond-like seed, much used by European confectioners. The pistachio tree is comprised in the natural order *anacardiaceæ* or terebinths, trees or shrubs remarkable for their caustic, gummy, resinous, and even milky juices. The *pistacia vera* is clothed with gray bark, its branches spreading and not numerous, its leaves winged, alternate, and on long petioles. The kernel of the pistachio nut is oily and mild to the taste; it is sometimes eaten raw, but more frequently in a dried state like almonds. The tree is cultivated in France and Italy; it will grow in any good garden soil, and can be propagated from cuttings and by seeds. It is recommended for ornament on account of the beauty of its foliage. There are several other species well known to botanists.

PISTIL, in botany, that part of the flower whose office is to elaborate the seed. The pistil occupies the most central part of the blossom, and is one of its essential organs. It may be regarded morphologically as the end of a branch or flower stalk. It consists of 3 parts, viz.: the ovary, a hollow case containing rudimentary seeds called ovules; the style, which is the tapering part above, and which may be very much elongated, or very short or even wholly wanting; and the stigma, which is the tip or some other part of the style, or when the style is wanting the summit of the ovary. The office of the stigma is to catch and detain the pollen, so that it may fertilize the ovules which are afterward to grow into perfect seeds.

PISTOJA, or PISTOIA (anc. *Pistoria* or *Pistorium*), a fortified city of Tuscany, in the prefecture of Florence, on the left bank of the Ombrone, 21 m. N. W. from Florence; pop. 12,000. It has a cathedral built in the 12th century. Iron, wool, silk, and leather are manufactured. In its neighborhood Catiline was defeated and slain (62 B. C.).

PISTOL, a small firearm to be carried about one's person, or in holsters at the saddle bow, named from the city of Pistoja in Tuscany, where it is stated pistols were first made. Mention is made of their use in 1544 under the reign of Francis I. of France, and in the time of his successor Henry II. the horsemen who carried them were called pistoliers. Being intended only for hand-to-hand encounters, no attempts were made to give them accuracy of aim, which indeed was altogether impracticable until the adoption of the firelock, toward the close of the 17th century, and such accuracy moreover was considered incompatible with their necessary shortness of barrel. It is indeed only within a few years past that pistols have been generally provided with sights. Yet some remarkable pistols were produced at an early period, which embody the peculiar principles of the most perfect instruments of the present day. A Spanish pistol made about the end of the 17th century is described by Greener as the most complete instrument of the kind which he had seen. "By moving a lever toward the but end while the muzzle is depressed, the lock is primed, half cocked, and the hammer shut down; return the lever, the powder is in the breech and the ball before it. We have seen it fire 26 shots without a failure and with one supply of ammunition. The magazine was in two tubes in the stock." The piece was finally burst in firing. It is stated by the same authority (Greener's "Gunnery in 1858," p. [illegible] that in the museum of artillery in Paris are revolving rifles, and swords and revolving pistols combined in one, which were produced more than 200 years ago. Some have 4, 5, and charge chambers. They would have prevented the establishment of Colt's patent, had not this been based on his causing the chambers to revolve in the act of cocking the lock. These improved pieces, so extraordinary for the time, never came into general use in consequence of their unavoidable clumsiness, each chamber having its own hammer and pan, and the inconvenience of keeping these primed. Such instruments, moreover, must have been extremely expensive, and but few workmen could have made them. Pistols of simpler form displaced them entirely; and these for the most part were clumsy instruments, especially the pistols made for naval service to be used in the close contests in boarding. They carried large balls, and were often double-barrelled, each barrel having its own lock and pan. Many were highly decorated with elaborate mountings upon their stocks, and an exterior finish of damaskeening or other ornamentation of the barrels; but little was done to perfect the character of barrels or of the locks. Great value was attached to these ornaments, and pistols of the Turks and Greeks are still remarkable for the extent to which this elaborate finish is carried.—Such was the character of pistols up to the time when Mr. Samuel Colt of Hartford, Conn., directed his attention to their improvement, and succeeded in bringing the instrument to a state of perfection never before attained. (See COLT, SAMUEL.) His first plan was to increase the number of discharges by arranging several barrels in one cylindrical group around a central spindle, and cause them to turn by each cocking of the lock sufficiently far to bring another barrel under the hammer. All the barrels being first loaded, they might then be discharged as rapidly as the hammer could be raised and the trigger pulled. Pistols of this kind have since been in use, but the plan finally adopted by Colt was to make a revolving chambered breech for the charges and a single barrel, in connection with which each chamber was brought in succession by drawing back the hammer to the full catch. At half cock the chamber is free to be turned round by hand, and in this state the receptacles are loaded by pouring in powder and placing a ball in each directly upon the powder, without wadding. A ramrod is permanently attached to the under side of the barrel, and is so contrived that by bringing down its free end it acts as a lever and strongly presses a short rod into one of the receptacles, driving the ball home, and effectually shutting in the powder. The charges are all thus rapidly introduced and secured, and percussion caps being placed on the nipples with which the chamber is provided, the piece is ready for service. The pistols are constructed with extreme nicety to guard against lateral escape of the fire and smoke, which by fouling the parts would obstruct the movements; and accuracy of aim is secured by a sight at the end of the barrel, and another in the hammer at the other end when this is set at full cock. The great value of Colt's pistols was fully established in the Texan and afterward in the Mexican war, and they proved of inestimable service to the allied armies in the Crimean war, and also to the English in their late encounter with the rebels in India. Still they failed to give entire satisfaction because of the necessity of stopping at every fire to cock the piece for the next shot. In several English and American pistols devices have been introduced for meeting this objection, and the pistols of Trantner and Dean of England have acquired much celebrity for the rapidity with which they may be fired; the pulling of the trigger raises the hammer to the full cock, when it is suddenly let go, and the action being repeated the same motion brings round another chamber which is immediately discharged. Several officers provided with these pistols, who were engaged at the battle of Inkerman, certified that they must have been cut down had there been the slightest delay for cocking their pistols. But others object to the *form* of lock on the ground that by the sudden liberation of the mainspring as it is pulled up, the aim is disturbed and the fire cannot be made with the accuracy of other pistols. Trantner, whose pistols are considered the best made in England, introduced some other modifications, one of which was the use of a patent lubricating bullet with a lubricating composition, by the use of which the fouling of the barrel is effectually prevented, and the piece may be fired several hundred times without cleaning. The great advantage of applying grease for this purpose has long been fully appreciated by our marksmen, and without it the barrel is soon obstructed with lead to such a degree that the balls fly very wild. The pistol made by Savage at Middletown, Conn., and now used very generally in the U. S. cavalry service, meets the objection against the English self-cocking pistols of their aim being destroyed by the introduction of a double trigger, one part of which is fitted for the middle finger and the other for the forefinger of the right hand. A pull with the one brings the hammer up and a fresh chamber round to its place. The pull being released, the pistol remains cocked and the cylinder springs forward, making its connection with the barrel tight. The trigger may be instantly pulled with the forefinger, discharging the piece. These movements may be continued with rapidity till the 6 barrels are discharged without removing the right hand from its place or calling the other into use. The large size and length of the pistol, and the accuracy with which it may be fired by means of its two sights, render it a formidable weapon even at long shots, and it is evidently extremely well adapted for use on horseback. At distances up to 150 yards a good marksman ought not to miss in any number of shots a target as large as a man. But for close encounters the small cartridge-loading pistols are the most recent and much the most efficient weapons. Several varieties of these have been brought out by American inventors, and are known as Smith and Wesson's, Warner's, and Allen's. They all have the revolving cylinder, which contains 7 chambers; and they differ from each other chiefly in the manner in which the cartridges are inserted into these chambers. In Smith and Wesson's the piece is so constructed that the barrel may be instantly turned at right angles with the stock, setting the cylinder free to be slipped off from the pin on which it turns, and the cartridges may then be slipped into the rear end of the chambers. These cartridges are copper caps resembling percussion caps, large enough to exactly fit the bore of the chamber. At the close end they are enlarged so as to form round the edges a thin receptacle for the percussion priming, and present a flange-like impediment to the cap entering entirely into the bore. Sufficient powder for a charge is placed in the base of the cap, and upon this the Minié ball is inserted, acting as a tight stopple, and projecting from the end like a cork from the neck of a phial. Whether carried in the pocket or introduced in the chambers of the pistol, the cartridges are always protected from dampness, and no injury can result to the barrel, however long they may be allowed to remain in it. They are prepared by the manufacturers and put up in boxes like percussion caps, and thus the use of powder flasks, percussion caps, and separate balls is entirely dispensed with, and the piece is completely charged with no more trouble and expenditure of time than usually attends the fixing of percussion caps upon the nipples. The slight projection of the cartridge cap outside the cylinder does not interfere with its revolution, which is effected by bringing the hammer back with the thumb of the right hand. The pistol thus cocked may be instantly fired by pulling the trigger with the forefinger of the same hand. After the chambers are discharged the cylinder is slipped off, and any discharged caps remaining in it are removed by passing the chambers in succession upon a fixed projecting rod beneath the barrel. They are then ready for recharging. In Warner's pistol the cartridge is introduced through an opening in the side of the stock at the rear of the chamber, and the cylinder may be removed sidewise when necessary for cleaning it, the barrel being immovably fixed to the stock. This is also the case with Allen's pistol, to supply whose chambers with cartridges the cylinder can be slipped out on one side, and when filled be returned to its place. A difficulty is encountered in increasing the size of the cartridge-loading pistols of this character. As the charges are increased the thickness of the copper cap must be proportionally increased, that the charge may not be thrown back. But if this cap is made of very thick copper the percussion powder may not be ignited by the blow of the hammer, and the charge will not then be fired. It is for this reason that these pistols are yet of diminutive sizes only, but they are nevertheless surprisingly efficient for their size, and some method will probably be devised of overcoming this obstacle to their capacity.

PISTOLE, a gold coin, equivalent in Spain to a quarter doubloon ($3.90). In Germany it is the common name of coins bearing the name of the state or sovereign who coined them, and worth about $3.70. The old Italian pistole or *doppia* is worth from $3.09 to $7.02.

PITCAIRN ISLAND, an island of the Pacific ocean, in lat. 25° 3′ S., long. 130° 8′ W.; extreme length about 2¼ m., breadth 1 m. It is elevated, the greatest height being nearly 2,500 feet above the sea, and is surrounded by cliffs which preclude the possibility of landing except in two or three spots. The temperature ranges between 59° and 90°, and the climate is remarkably healthy. There are a few small streams, but they are liable to fail at certain seasons, when the inhabitants depend upon water preserved in tanks. The soil is rich and fertile, and the island is everywhere thickly clothed with a luxuriant vegetation. Several tropical fruits and vegetables are indigenous, and many others, together with some of those belonging to temperate regions, have been successfully introduced. All the domestic animals except the horse have also been introduced, and goats are very numerous in the more inaccessible parts of the island.—Pitcairn island was discovered by Carteret in 1767, and named after one of his officers who was the first to see it. Its chief interest, however, is derived from the mutiny of the Bounty, a vessel sent by the British government to convey plants of the breadfruit tree from Tahiti to the West Indies. The Bounty arrived at Tahiti at a wrong season for transplanting, and was compelled to remain there for 6 months, during which time the crew formed connections with the natives. A few days after sailing, in April, 1789, the crew mutinied, and when they had sent Capt. Bligh and those who would not join them adrift in an open boat, they bore away for Tahiti. Here one of the crew named Christian and 8 others, after the rest had landed, induced 9 native women and 9 men to come aboard, when they put to sea and were not heard of for many years. In 1808 Capt. Folger of Nantucket, while on a sealing voyage in the Pacific, called at Pitcairn island, and, having supposed it to be uninhabited, was much surprised to see a canoe with two men of a light brownish complexion approach his vessel, and request in good English that a rope should be thrown to them. They were the descendants of the remnant of the long lost and long sought crew. Determined to cut off all traces of themselves, when the mutineers reached Pitcairn island they ran the Bounty ashore, where, after stripping her of all that might be useful to them, they burned her. Christian and his associates took the Tahitian women as wives and reduced the men to bondage. They appear to have got on well for a time, made good houses, and cultivated a considerable extent of ground; but at length the slaves rebelling, they were forced to destroy them all, not however before 8 of the masters had been killed in the affray, among whom was Christian. One of the mutineers committed suicide, and another, becoming deranged and exceedingly violent, was knocked on the head with an axe by his companions as a measure of self-defence. The rest all died natural deaths, and at the time of Capt. Folger's visit Adams was the only survivor of the mutineers. (See ADAMS, JOHN.) He drew up a simple code of laws by which the islanders are still governed, and to which they are very much attached. They are an honest, kind-hearted people, of very simple habits. When not otherwise occupied, they often hold meetings among themselves, at which the women take no inconsiderable share of the conversation. The women are more industrious than the men, and assist in the cultivation of the ground. In 1856 the whole community was removed, by some well-wishers in England and Australia, to Norfolk island; but the greater part of them were much dissatisfied with the change, and early in 1859 two families, numbering 17 souls, returned to Pitcairn island. The number remaining at Norfolk island was 202.

PITCH (Gr. πιττα), a black resinous substance constituting the residuum when the volatile portions of tar are driven off by heat. When warm it is soft and sticky, but becomes solid and brittle when cold. It is one of the products of the pine tree classed in commerce as naval stores, and is largely produced for consumption in ship building, being used to pay the seams and thus render them impervious to water. It is also used in medicine as a mild stimulant and tonic, and is administered in pills for cutaneous diseases and for piles.—Burgundy pitch is used for plasters, and when applied for some time to the skin acts as a rubefacient, exciting slight inflammation and serous effusion, and relieving chronic affections of the chest and rheumatic pains. It is prepared from the resinous matter that exudes from the Norway spruce (*abies excelsa*), and from the European silver fir tree (*A. picea*). The resin is melted in hot water, and strained through coarse cloths. This variety is yellow, and is distinguished from the compounds of common pitch, rosin, and turpentine, made to resemble it, by its peculiar odor. It is largely produced in the neighborhood of Neufchâtel, and thence furnished to commerce.—Canada pitch resembles the preceding in its properties, and is prepared from the inspissated juice of the hemlock spruce (*A. Canadensis*). The juice exudes spontaneously from old hemlock trees, and hardens upon the bark, which is stripped off, broken in pieces, and boiled in water. The pitch as it rises to the surface is skimmed off, and is purified by a second boiling. It consists of resin with a little volatile oil. It melts at 109° F., and is almost too soft at the temperature of the body to be worn as a plaster.

PITKIN, Timothy, an American historian, born in Farmington, Conn., in 1765, died in New Haven, Dec. 18, 1847. He was graduated at Yale college in 1785, studied law, became a member of the state legislature, where for 5 sessions he was speaker of the house, and from 1805 to 1819 was a representative in congress. In 1816 he published "A Statistical View of the Commerce of the United States" (2d ed., New Haven, 1835); and in 1828, "Political and Civil History of the United States from 1763 to the Close of Washington's Administration" (2 vols. 8vo., New Haven).

PITT, an E. co. of N. C., intersected by Tar river; area, about 700 sq. m.; pop. in 1860, 16,080, of whom 8,473 were slaves. It has a level surface and sandy soil. The productions in 1850 were 458,478 bushels of Indian corn, 102,352 of sweet potatoes, and 171 bales of cotton. There were 12 grist mills, 5 saw mills, 25 tar and turpentine manufactories, 18 churches, and 1,095 pupils attending public schools. Capital, Greenville.

PITT, Christopher, an English clergyman and poet, born in Blandford in 1699, died April 13, 1748. He was educated at Oxford, where he made a translation of Lucan's *Pharsalia*, which has not been preserved, and was chosen to a fellowship of New college. In 1722 he obtained the rectory of Pimperne in Dorsetshire, but he continued at Oxford until 1724, when having received the degree of M.A. he withdrew to his living, and there passed the rest of his days, greatly beloved for his benevolence. In 1727 he published a collection of his poems under the title of "A Miscellany," and two years later a translation of the first book of Virgil's Æneid, and subsequently at intervals the remaining 11 books. His version is correct, and contains many short passages of singular merit, but it has never enjoyed the same popularity as the more spirited and vigorous translation of Dryden. Pitt also made an admired translation of Vida's "Art of Poetry."

PITT, William, first earl of Chatham, an English orator and statesman, born at Westminster, Nov. 15, 1708, died at Hayes, May 11, 1778. He was the son of Robert Pitt of Boconnock in Cornwall, and grandson of Thomas Pitt, who obtained the sobriquet of Diamond Pitt from a large diamond which came into his possession in India, where he had been governor of Fort St. George at Madras, and which he sold to the regent Orleans for £135,000. William Pitt received his early education at Eton, and in 1726 entered Trinity college, Oxford, which he quitted without taking a degree, but with a high reputation for talent and for skill in elocution. He travelled in France and Italy, and on his return obtained a commission in the army as a cornet of dragoons. In 1735 he entered the house of commons for the family borough of Old Sarum. His abilities and his eloquence soon commanded attention, and made him the most formidable opponent of the ministry of Sir Robert Walpole, who in his vexation caused the "terrible cornet of horse," as he called him, to be dismissed from the service, a paltry revenge which only spurred Pitt to still fiercer attacks. "His figure when he first appeared in parliament," says Macaulay, "was strikingly graceful and commanding, his features high and noble, his eyes full of fire. His voice, even when it sank to a whisper, was heard to the remotest benches; when he strained it to its full extent, the sound rose like the swell of the organ of a great cathedral, shook the house with its peal, and was heard through lobbies and down staircases, to the court of requests and the precincts of Westminster hall. He cultivated all these eminent advantages with the most assiduous care. His action is described by a very malignant observer as equal to that of Garrick. His play of countenance was wonderful; he frequently disconcerted a hostile orator by a single glance of indignation or scorn. Every tone, from the thrilling cry to the impassioned aside, was perfectly at his command." In the debate, in 1740, on the bill for registering seamen, he was taunted by Horatio Walpole with his youth, though he was then 32 years of age, and made the celebrated reply, of which Dr. Johnson gave in the "Gentleman's Magazine" the commonly received version: "I will not attempt to determine whether youth can justly be imputed to any man as a reproach; but I will affirm that the wretch who, after having seen the consequences of repeated errors, continues still to blunder, and whose age has only added obstinacy to stupidity, is surely the object of either abhorrence or contempt, and deserves not that his gray head should secure him from insult." He gradually obtained the popular reputation of being one of the most powerful, vigilant, and patriotic opponents in parliament of unconstitutional and unwise measures. The famous duchess of Marlborough left to Pitt when she died in 1744 a legacy of £10,000, "for having defended the laws of his country and endeavored to save it from ruin." In the following year the duke of Newcastle, who had become prime minister, wished to have him made secretary of war; but the king hated Pitt, and would not consent to the appointment. In 1746 he was appointed joint vice-treasurer of Ireland and treasurer and paymaster of the army. He filled these offices with such integrity, refusing to accept the ordinary perquisites, which had made them in less scrupulous hands the most lucrative positions in the government, that his reputation rose to the highest pitch. In 1755 he determined to oppose certain measures of the ministry, and accordingly resigned his posts; but the popular discontent at his absence from office was so great that it was deemed prudent to invite him to return to the ministry with the position of secretary of state. The king however continued bitterly hostile to him, and in a short time dismissed him from office. The public indignation at this rose to such a degree that he was restored in 1757 with additional powers, which made him in fact prime minister. England was then engaged in the 7 years' war, which had opened disastrously for her arms in almost every part of the world. To Pitt was now intrusted the supreme direction of the war and of foreign affairs. Under his vigorous and skilful administration the aspect of things speedily changed. A succession of victories and conquests filled the kingdom with rejoicing, and raised still higher the already great fame of the minister. In July, 1758, Louisburg was taken, the whole island of Cape Breton was reduced, and the French fleet was destroyed. The year 1759 opened with the conquest of Goree. Next fell Guadeloupe; then Ticonderoga; then Niagara. The Toulon squadron was completely defeated by Admiral Boscawen off Cape Lagos, and this was followed by the news of the crowning triumph of Wolfe on the heights of Abraham, the surrender of Quebec, and the conquest of Canada. Next a large fleet under Conflans was completely defeated by Hawke, and a succession of English victories almost annihilated the French navy. In the mean time vast conquests had been made in India, repeated victories won over the French generals there, and a mighty empire founded in the space of three years. On the continent Pitt's measures were equally successful. When he came into power Hanover was almost completely in the hands of France; but the invaders were speedily driven out, and were beaten in 1758 at Crefeld, and in 1759 still more completely at Minden. At the same time the nation exhibited all the signs of wealth and prosperity; the merchants of London had never been more thriving, and the importance of several great commercial towns, Glasgow in particular, dates from this period. "The situation which Pitt occupied at the close of the reign of George II.," says Macaulay, "was the most enviable ever occupied by any public man in English history. He had conciliated the king; he domineered over the house of commons; he was adored by the people; he was admired by all Europe. He was the first Englishman of his times; and he had made England the first country in the world. The great commoner—the name by which he was often designated—might look down with scorn on coronets and garters." George II. died Oct. 25, 1760, and was succeeded by George III. Just at this period the French court had succeeded in obtaining the coöperation of Spain by a secret treaty known as the "family compact." Pitt, fully informed of the hostile intentions of Spain, insisted on declaring war against her before she had time for preparation. His colleagues in the ministry opposed this bold policy, and Pitt resigned Oct. 5, 1761. His wife was created Baroness Chatham in her own right, and a pension of £3,000 was settled on himself, Lady Chatham, and his eldest son. The war, however, was continued with vigor and success, and in spite of Pitt's opposition in the house of commons peace was concluded Feb. 10, 1763. He maintained his dignity and his popularity in his retirement, and came forward in parliament only when great questions were to be discussed. In 1764 he spoke against general warrants with all his customary force and eloquence, and in 1766 he opposed the American stamp act with equal vigor. In that year a new ministry was formed, and he was appointed lord privy seal, and at the same time was created a peer with the titles of Viscount Pitt and earl of Chatham. His acceptance of a peerage very much damaged his popularity. The people had been proud of him as the "great commoner," and his elevation in rank was thought to have lowered his true dignity. He did not long continue in office. In Nov. 1768, he resigned the place of lord privy seal, and never afterward held any public employment. He had been from childhood tormented by the gout, which of late years afflicted him so severely that he now seldom appeared in public, but spent much of his time in bed, employing his wife as an amanuensis in his most confidential correspondence. In the intervals of pain he sometimes appeared in the house of lords to speak on questions of great importance. In 1775, '6, and '7 he opposed with energy the measures of the ministry in the American colonies, and several of his speeches on that subject are yet popular in the United States for their lofty and impassioned eloquence. His last appearance in public was on April 2, 1778, when he went from his sick bed to the house of lords to speak against a motion to acknowledge the independence of America. He appeared swathed in flannel, crutch in hand, emaciated and debilitated, and supported by his son, and son-in-law, Lord Mahon. He protested with great animation against the dismemberment of the empire and the degradation of the power of England. The house listened in solemn silence and with profound respect. At the end of his speech he fell in an apoplectic fit, and was borne home to die a few weeks afterward.

The death of so great a statesman and orator, falling in the attempt to rouse the spirit of his countrymen, made a most profound impression on England. All parties united in doing honor to his memory, and in acknowledging his lofty genius, his unsullied probity, and his unrivalled public services. His debts were paid by the nation, his family provided for, and his body was buried in Westminster abbey. Lord Macaulay says, at the close of an article in the "Edinburgh Review:" "Chatham sleeps near the northern door of the church, in a spot which has ever since been appropriated to statesmen, as the other end of the same transept has long been to poets. Mansfield rests there, and the second William Pitt, and Fox, and Grattan, and Canning, and Wilberforce. In no other cemetery do so many great citizens lie within so narrow a space. High over these venerable graves towers the stately monument of Chatham, and from above, his own effigy, graven by a cunning hand, seems still with eagle face and outstretched arm to bid England be of good cheer and hurl defiance to her foes. The generation which reared that memorial of him has disappeared. The time has come when the rash and indiscriminate judgments which his contemporaries passed on his character may be calmly revised by history. And history, while, for the warning of vehement, high, and daring natures, she notes his many errors, will yet deliberately pronounce, that among the eminent men whose bones lie near his, scarcely one has left a more stainless, and none a more splendid name."—Of Chatham's writings, there have been published a small volume of letters to his nephew Thomas Pitt, Lord Camelford, and his "Correspondence" (4 vols., London, 1838-'40). His title expired with his eldest son (2d earl), a general officer of unenviable notoriety, in 1835. His life has been written by the Rev. Francis Thackeray (2 vols. 4to., London, 1827).

PITT, William, an English statesman, second son of the preceding, born at Hayes, county of Kent, May 28, 1759, died at Putney, Jan. 23, 1806. He was a singularly precocious child, and even at the age of 7 was remarkable for the interest which he took in grave subjects, for the ardor with which he pursued his studies, and the sense and vivacity of his remarks. At 14 he had the intellect of a man, and wrote a tragedy not worse than many productions which have been printed by persons of mature years. His physical development was not equal to his intellectual. He was tall, slender, and so sickly that he was educated at home instead of being sent like other boys of the same rank to the great public schools. Before he had completed his 15th year he was fitted to enter the university, and was sent to Pembroke hall, Cambridge, where he was first under the charge of a tutor named Pretyman, for whom he contracted a warm affection, and whom he afterward made bishop of Lincoln, a favor which his preceptor endeavored to requite by writing a life of his pupil which enjoys, according to Macaulay, the distinction of being the worst biographical work of its size in the world. At the university he was distinguished for mathematical talent and for proficiency in classical learning, but paid comparatively little attention to modern literature. Of the living languages he had no knowledge except an imperfect acquaintance with French. His favorite authors were Shakespeare, Milton, Locke, Adam Smith, and Bolingbroke. His father had trained him from infancy in the art of managing his voice, which was naturally clear and deep-toned, and his whole education had been directed to the point of making him a great parliamentary orator. On quitting the university he studied law in Lincoln's Inn, and at the age of 21, two years after his father's death, he became a member of parliament for the borough of Appleby. The party with which he acted was a section of the opposition composed of the old followers of his father, with the earl of Shelburne, Lord Camden, and Col. Barré at their head. His first speech, Feb. 26, 1781, was in favor of Burke's plan of economical reform, and made a great impression. Burke exclaimed on hearing him: "It is not a chip of the old block; it is the old block itself." Some one said to Fox: "Pitt will be one of the first men in parliament." "He is so already," answered Fox. Subsequently during the session the young orator twice addressed the house with marked success. In the next session he distinguished himself still more brilliantly, and on the rise to power of the Rockingham ministry he was offered the highly lucrative office of vice-treasurer of Ireland. Though his income at this time was very small, he declined the offer without hesitation, declaring that he would accept no post that did not give him a seat in the cabinet. Three months later, on the death of Rockingham, his successor Shelburne found that Pitt, although then but 23 years old, was the only member of his party in the house of commons who had the courage and the eloquence required to confront Fox and Burke and the other great orators of the opposition. He was accordingly brought into the cabinet as chancellor of the exchequer. In the following year the Shelburne ministry resigned, and the king, unwilling to take Fox as his successor, urgently pressed Pitt to accept the premiership. With great judgment he steadily refused the tempting offer, satisfied that he could not at that time form a stable administration. He took his seat on the opposition benches, and advocated a project of parliamentary reform which was rejected. When parliament adjourned he visited the continent in company with William Wilberforce, and was received by the Parisians in the most distinguished manner. Parliament reassembled in Nov. 1783. The ministry brought forward a bill for the government of India, which excited the fiercest opposition and was defeated in the house of lords. The ministry resigned, and Pitt succeeded as prime minister, being appointed first lord of the treasury and chancellor of the exchequer. He took office surrounded by difficulties of the most formidable kind. Among his colleagues in the house of commons there was not a single orator of note, while the opposition was led by Fox, Burke, Sheridan, and North. His policy, however, was from the outset firm and unflinching. He maintained the contest with haughty resolution from Dec. 17, 1783, to March 8, 1784, notwithstanding he was defeated in 16 divisions. Though the house of commons was hostile, the king and the people gave him the warmest support. In the midst of the struggle the clerkship of the pells, a sinecure place worth £3,000 a year for life, and one that could be held together with a seat in parliament, became vacant. Everybody thought that Pitt, whose whole private income was only £300 a year, would appoint himself; but he gave the office to Col. Barré, who was old and blind. "No minister was ever more rancorously libelled," says Macaulay; "but even when he was overwhelmed with debt, when millions were passing through his hands, when the wealthiest magnates of the realm were soliciting him for marquisates and garters, his bitterest enemies did not dare to accuse him of touching unlawful gain." The courage and determination of the young premier at length triumphed. The opposition majority was reduced to one, and parliament was dissolved with the coalition of Fox and North demoralized and practically defeated. The appeal to the country met with an enthusiastic response, 160 of the coalition members losing their seats, and Pitt being returned at the head of the poll for the university of Cambridge. He was now, at the age of 25, the greatest subject that England had seen for many generations. No minister in modern times had ever been so powerful and so popular. Macaulay terms him at this period the greatest master of the whole art of parliamentary government that has ever existed, a greater than Montague or Walpole, a greater than his father Chatham or his rival Fox, a greater than either of his illustrious successors Canning and Peel. "At his first appearance in parliament he showed himself superior to all his contemporaries in command of language. He could pour forth a long succession of round and stately periods without premeditation, without ever pausing for a word, without ever repeating a word, in a voice of silver clearness, and with a pronunciation so articulate that not a letter was slurred over. He had less amplitude of mind and less richness of imagination than Burke, less ingenuity than Windham, less wit than Sheridan, less perfect mastery of dialectical force and less of that highest sort of eloquence which consists of reason and passion fused together than Fox. Yet the almost unanimous judgment of those who were in the habit of listening to that remarkable race of men laced Pitt, as a speaker, above Burke, above Windham, above Sheridan, and not below Fox. His declamation was copious, polished, and splendid. In power of sarcasm he was probably not surpassed by any speaker, ancient or modern, and of this formidable weapon he made merciless use." On March 29, 1786, Pitt in a speech of 6 hours, delivered without notes and without a moment's hesitation, brought forward a scheme for the redemption of the national debt by means of a sinking fund, and supported it by a vast and elaborate array of figures and arguments. It was agreed to by the house without a single dissentient vote, and raised his reputation as a financier to a degree which subsequent experience has not justified. In the autumn of 1788 George III. became insane. The opposition, with whom the prince of Wales, afterward George IV., had affiliated, contended that the prince, who all agreed should be regent during the king's insanity, was as a matter of course entitled to the full powers of the crown. Pitt maintained that it belonged to parliament to determine with what degree of power the regent should be intrusted. The people, to whom the prince's vices made him odious, sided with Pitt, and supported him with enthusiasm during a long and violent contest on the subject; and when that contest was terminated by the king's unexpected recovery, the popularity of the minister was greater than ever. In the same year Pitt, who was always strongly opposed to slavery and the slave trade, carried by his eloquence and determination, against the opposition of some of his own colleagues, a bill to mitigate the horrors of the middle passage. Until the outbreak of the excesses of the French revolution his administration had been distinguished for its humane and peaceful character, for efforts at constitutional reform, and regard for freedom and order. He looked at first with approbation on the French movement for constitutional liberty, but in common with the vast majority of the English nation he was shocked and revolted by the atrocities of the revolutionists. He however labored hard to avert the war with France, but was at length forced by popular pressure and the current of events into hostilities. His military administration was feeble and unskilful. He underrated the resources and misunderstood the character of the French people, and made no adequate use of the means at his command. For a long series of years the operations of the English on land were marked only by inefficiency, blunders, and disasters; and on sea for a long while affairs went little better. Pitt had made his elder brother, the earl of Chatham, first lord of the admiralty, a post for which he was totally unfitted; and nothing was done by the navy till Earl Spencer succeeded him, under whose administration two great naval victories were won within a year. In spite of his blunders and failures in foreign expeditions, Pitt's extraordinary genius as a parliamentary leader continued to him the absolute control of the house of commons, and at length the opposition to him there substantially vanished away. In 1799 the largest minority that could be mustered on any question was only 25 votes. Most of the leaders of the opposition had given in their adhesion to the administration, and Fox, the greatest of them all, had withdrawn from the field. In his domestic policy Pitt was vigorous and severe, and effectually repressed the revolutionary spirit in the British islands by a series of high-handed measures and arbitrary enactments which rendered him exceedingly odious to the liberal part of the people. He formed great plans however for the benefit of Ireland, but could only effect the legislative union with Great Britain, his project of Catholic emancipation being defeated by the obstinate prejudices of the king. Finding the monarch immovable on this point, Pitt resigned and Addington became premier. Pitt at first made no opposition to the new ministry, and for a considerable period lived in retirement, so embarrassed in circumstances, after 20 years of absolute power, as to have had serious thoughts of returning to his profession for subsistence. But when in May, 1803, the ambitious designs of Napoleon drove England to break the peace of Amiens, he appeared in parliament and made a great speech in favor of the war. In the following year the weakness of Addington and his colleagues became so apparent that the king was forced to recall Pitt to the head of affairs. Pitt desired to form a cabinet of the first men in the kingdom without reference to past party affinities; but the prejudices of the half insane monarch against Fox were insurmountable, and as Fox's friends would not take office while he was excluded, the new government was formed chiefly of the wreck of Addington's administration, with the addition of a few personal friends of the premier, of whom Harrowby, Melville, and Canning were the most eminent. Pitt was soon beset with troubles of fearful magnitude. He was deprived by various causes of his ablest coadjutors. Harrowby fell sick, and Melville was disgraced and ejected from office for questionable pecuniary transactions. On the continent Napoleon was everywhere victorious in spite of the mighty coalitions which the skill of Pitt and the money of England formed against him. The haughty and indomitable minister grew ill with anxiety and grief. The surrender of the Austrian army at Ulm gave him a shock from which he never fully recovered, though 4 days later the glorious news of the victory of Trafalgar for a moment revived his spirits. He finally gave way on hearing of the battle of Austerlitz, after which he rapidly declined and died in a few weeks. He was honored by parliament with a public funeral, and his remains were deposited near those of his father in Westminster abbey.—See "Life of William Pitt," by Earl Stanhope (4 vols., London, 1861 *et seq.*).

PITTACAL (Gr. πίττα, pitch, and καλός, beautiful), one of the principles discovered by Reichenbach in wood tar. It is a solid compound of a deep blue color precipitated from picamar, which is the bitter oil of tar deprived of its acid by the addition of barytes water. Pittacal bears some resemblance to indigo, assumes a metallic lustre by friction, and is used to dye a fast blue upon linen and cotton with tin and aluminous mordants.

PITTACUS, one of the seven wise men of Greece, born in Mytilene in Lesbos about 652 B. C., died about 569. He was the son of Hyrradius, and is first mentioned as engaged in a conspiracy with the brothers of the poet Alcæus, by which Melanchrus, tyrant of Mytilene, was slain about 612. About this time the Athenians and Mytilenæans were engaged in a war for the possession of Sigeum in the Troad. A battle ensued, in which the latter were vanquished; but Pittacus succeeded in slaying with his own hand Phrynon, the leader of the enemy, who was an Olympic victor, and whom he overcame by entangling him in a net. For his conduct he was offered great rewards, but would take only so much land as he could throw his spear over; and this was known to a late age as "the Pittacian land." Mytilene at this time was agitated by the conflict between the democratic and aristocratic parties, the latter of which was led by Alcæus and his brother. These were at length worsted and banished; but the exiles were not inclined to submit, and kept Mytilene in a state of alarm by their efforts to return, so that the inhabitants finally chose Pittacus, who belonged to the democratic party, as a ruler with absolute power, under the title of *æsymnetes*, an office which differed from that of a tyrant in being elective. This position Pittacus held from 589 to 579. The lost poems of Alcæus abounded with bitter invectives against him, describing him as an oppressor, and ridiculing the peculiarities of his personal appearance. He enacted, among other laws, that offences committed in a state of intoxication should be visited with double penalties. He was celebrated as an elegiac poet; but only a few lines of his are extant, preserved by Diogenes Laërtius.

PITTSBURG, a city, and the capital of Allegheny co., Penn., situated at the confluence of the Allegheny and Monongahela rivers, which here form the Ohio, in lat. 40° 26' 34" N., long. 80° 2' 36" W.; pop. of the city proper in 1840, 21,115; in 1850, 46,601; in 1860, 49,216, or including the suburbs, 115,000. The densely built business portion occupies the extremity of the peninsula between the two rivers, which meet at an angle of about 35°, and the outskirts extend along the bank of each stream, having between them a cliff 300 feet high, which thrusts itself forward from the table-land in the rear. On this elevation, which is known as Grant's Hill, are the reservoirs that supply the city with pure water from the Allegheny river.—Pittsburg is styled the "smoky city" on account of the heavy clouds of smoke which constantly hang over it, produced by burning bituminous coal in all dwellings and manufacturing establishments. This is the great shipping port for coal for all parts of the Mississippi valley. The amount shipped during 1860 was 1,600,000 tons. The Monongahela river, from whose banks the coal is obtained, has been improved by slackwater dams and locks so as to render it navigable in all seasons. There are 65 companies engaged in mining, 3,500 men employed in the mines, and more than $1,000,000 invested in improvements, and $350,000 in coal tugs for towing the coal to market. The value of coal lands is from $400 to $800 per acre. From the first Pittsburg has been a manufacturing city. In articles of iron it is surpassed by no city in the Union. There are now 28 large iron and steel works in operation, which consume more than $7,000,000 worth of material annually, such as pig iron, blooms, scrap iron, coal, coke, fire clay, &c. They employ about 6,000 hands, and their annual product amounts to $12,000,000. The value of nails, spikes, and rivets alone for 1857 was $3,000,000, and blister, plough, and cast steel $2,000,000. Other articles of manufacture are axles, vices, springs, crow-bars, sheet, bar, and boiler iron, gas pipe, &c. There are 16 founderies of the yearly capacity of 45,000 tons, consuming pig iron, coal, coke, fire brick, and other materials, to the value of $700,000 annually, employing 800 hands, and producing castings to the value of $1,250,000. An immense cannon foundery is in operation, which supplies heavy ordnance for the government. The great "Union" gun, the largest in the world, cast here in Jan. 1861, weighed 49,050 lbs. There are machine shops, manufactories of boilers, shovels, ploughs, axes, safes, cutlery, files, wire, rifles, guns, and revolvers. About 350 steam engines are built here annually. Among other establishments are 2 copper smelting and rolling mills employing 300 men, 6 cotton mills employing more than 1,000 hands, 9 white lead factories, and a large number of glass factories. In 1857 there were 34 glass houses, employing more than 2,000 hands, consuming annually $2,250,000 worth of materials, and making $3,000,000 worth of glass. Steamboats are built here for all western and southern rivers, and the number of boats now (1861) owned in the city is 167, with an aggregate burden of 26,974 tons. The value of flat-boats used for carrying coal to market (where the boat is always sold) is about $250,000 per annum. The whole commercial and manufacturing product of the city in 1850 amounted to $50,000,000, in 1860 to near $100,000,000.—The most imposing public buildings are the court house and new Roman Catholic cathedral. The latter is the largest building of the kind in America except the cathedral at Montreal. Many fine shops and warehouses are built entirely of iron, which is one of the best and cheapest materials in use. There are about 115 churches in the city and suburbs. The city is connected with Alleghany City, on the opposite side of the Alleghany river, by 4 bridges, one of which is a railroad bridge, and a suspension aqueduct for canal purposes. One of the finest suspension bridges in the world was erected here in 1860. Two bridges connect the city with Birmingham and Sligo on the Monongahela side. The railroads in operation are the Pennsylvania central, the Pittsburg, Fort Wayne, and Chicago, the Cleveland and Pittsburg, the Pittsburg and Connellsville, and the Alleghany valley. The Pittsburg and Connellsville railroad is completed to Connellsville, 60 m., and is destined to extend to Cumberland, Md., on the Baltimore and Ohio railroad. The Alleghany valley railroad is intended to meet the New York and Erie railroad at Olean, and 44 m. of it are in working order. The Steubenville and Indiana railroad is partly completed W. of Steubenville, O., and is nearly ready for the iron between Pittsburg and Steubenville. The Chartiers valley railroad, connecting Pittsburg and Washington, Penn., 30 m. in length, is partially graded. There are 4 city passenger railroads, 3 of which are in active operation. The city has an excellent system of public schools, and is the seat of the western theological seminary of the Old School Presbyterian church; the western university of Pennsylvania; two commercial colleges, an insane asylum, an observatory, and a marine hospital. There are 3 public libraries containing about 6,000 volumes. There are 10 or 11 newspapers, including 2 in the German language, and the city has a well supported theatre. There is a U. S. arsenal situated here, containing a large supply of heavy ordnance. There are 6 banks of issue, with an aggregate capital of $4,300,000, and 3 banks of deposit, beside savings banks and private banking houses.—The early history of Pittsburg, or Fort Pitt, as it was formerly called, is full of interest. It was first subject to Great Britain, then to France, then reconquered by the English. The English claimed title to the territory under a charter from the crown, strengthened by a treaty with the Iroquois; the French laid claim on the ground of discovery. In Feb. 1754, the English commenced building a stockade at the river junction, but were driven from it in April by a French force under Captain Contrecœur, who proceeded at once to erect a fort, which he called Duquesne, in honor of the governor of Canada. This fort at once became the great centre of all the military operations of the French in this part of the country, and its commanding position rendered its restoration to the English a matter of the first importance. Accordingly, in 1755, Gen. Braddock, at the head of the largest expedition that had ever crossed the Alleghanies, was sent to recapture it. On July 9, 1755, he was met and defeated by the French and Indians at a point on the Monongahela 12 m. above the fort. Twelve of the British soldiers taken prisoners on that occasion were burned by the savages. A force of 800 men under Major Grant was cut to pieces in a second attempt to take the fort, Oct. 15, 1758; but a third, by 6,000 men under Gen. Forbes, Nov. 25, 1758, was successful, the French, disheartened by the failure of several attacks on the advancing army, having abandoned and set fire to it on the day preceding. A new and large fort was built and completed about Jan. 1759. It was called Fort Pitt, in honor of the British minister. Several expeditions were fitted out against it by the French, but they all failed. In 1764 the first efforts were made toward building a town. In Oct. 1772, the post was abandoned by the English. A controversy between Pennsylvania and Virginia as to the boundary line was the subject of much negotiation, and gave rise to ill feeling between the two states, Virginia claiming the territory on which the city stands under a charter from James I., and Pennsylvania under a charter from Charles II. A company of Virginians took possession of the fort under an order from the Virginia convention, Aug. 11, 1775. On Aug. 31, 1779, commissioners appointed by the two provinces met in Baltimore, and agreed upon the boundary, which was duly ratified by their respective legislatures. During the excise troubles of 1791-'4, Pittsburg was the scene of much violence. It was incorporated as a borough in 1804, and chartered as a city in 1816. In 1845 a conflagration destroyed the entire business quarter, consuming $2,000,000 worth of property.

PITTSFIELD, a town of Berkshire co., Mass., on the line of the western railroad, 151 m. W. from Boston, and 49 m. E. S. E. from Albany, and a terminus of the Housatonic and of the Pittsfield and North Adams railroads; pop. in 1855, 8,050. It is beautifully situated in an elevated valley surrounded by mountains, and is regularly laid out, with houses generally of wood and very neatly built. In 1855 there were 2 cotton mills, manufacturing 1,500,000 yards of cloth, and 6 woollen mills, producing 567,000 yards of broadcloth, and 800,000 of satinet, beside a number of other manufactories; total value of manufactured goods, $1,129,000. The Berkshire medical institution, founded in 1822, and the young ladies' institute, are both of excellent repute, and in a prosperous condition. There are 2 banks, and 9 churches, viz.: 1 Baptist, 3 Congregational, 1 Episcopal, 1 German, 2 Methodist, and 1 Roman Catholic, several of which are very handsome edifices.

PITTSYLVANIA, a S. co. of Va., bordering on N. C., bounded N. by the Staunton, intersected by the Banister through the middle, and drained by the Dan river on the S.; area, about 900 sq. m.; pop. in 1860, 32,104, of whom 14,340 were slaves. It has a diversified surface and fertile soil. The productions in 1850 were 654,015 bushels of Indian corn, 120,994 of wheat, 23,954 lbs. of wool, and 4,790,757 lbs. of tobacco. There were 25 grist mills, 18 saw mills, 7 tanneries, 8 distilleries, 43 tobacco factories, 60 churches, and 697 pupils attending public schools. Value of real estate in 1856, $4,691,571, being an increase of 62 per cent. since 1850. Capital, Competition.

PIUS, the name of 9 popes, the most celebrated of whom are the following. I. PIUS II. (See ÆNEAS SYLVIUS.) II. PIUS VI. (GIOVANNI ANGELO BRASCHI), born in Cesena in 1717, died in Valence, France, Aug. 29, 1799. Before his elevation to the pontificate he had held the office of papal treasurer. Elected to succeed Clement XIV. in 1775, he applied himself at once to the work of reform in both church and state, but met with great opposition, especially from Leopold I., grand duke of Tuscany, with whom he had a serious dispute in 1777. Soon afterward becoming involved in a disagreement with Leopold's brother, Joseph II. of Austria, who had suppressed hundreds of convents in his dominions and enacted various measures tending to withdraw the clergy of the empire from the authority of the Roman see, Pius made a journey to Vienna in 1782, but failed to effect a settlement of the points in dispute. The Jansenist synod of Pistoja in Tuscany, convened by Bishop Ricci in 1786, revived the disputes with Leopold; but on the accession of the grand duke to the imperial crown after the death of his brother (1790) a complete reconciliation was effected, both with Tuscany and Austria. In the mean time, however, the unfortunate pope had found a new enemy in France, where the property of the church was confiscated, and priests who refused to subscribe to the "civil constitution of the clergy" were put to death or banished. While condemning these violent proceedings, Pius VI. refused to join the coalition of European states against France; but an occurrence at Rome in 1793 led to still more hostile relations with the new republic. An agent of the revolutionary party named Basseville was assassinated by a mob whom he had provoked by his own imprudence, and the papal government, though it made every effort to have the murderers punished, was charged with being a party to the outrage, and threatened with summary vengeance. In 1796 Bonaparte entered Italy, took possession of the legations, and was marching upon Rome when the pope proposed a negotiation; and in Feb. 1797, a peace was signed at Tolentino, whereby the holy see agreed to surrender Avignon, Venaissin, and the legations of Ferrara, Bologna, and the Romagna; to relinquish the right of garrison in Ancona; and to give to the French 31,000,000 francs and some of the finest works of art in Rome. The fulfilment of these conditions brought the pope to the verge of ruin. After the voluntary contributions of the richest families of the city, it was still necessary to resort to an issue of paper money in order to raise the 31,000,000 francs, the payment of which the directory did not fail to urge with the utmost haste. The French stirred up revolutionary movements in Rome, and in an attempt to suppress them Gen. Duphot, an *attaché* of the French embassy, was killed by the papal troops. This gave the directory a long coveted pretext for dethroning the pontiff. On Feb. 10, 1798, Gen. Berthier entered Rome without opposition, and on the 15th declared a republic. On the 20th, having been allowed two days for preparation, the pope was escorted by a strong detachment of cavalry along the road to Florence. He lodged first at a convent near Sienna, and afterward with the Carthusians in the vicinity of Florence. In the following year the French having taken possession of Tuscany ordered him to be removed to Grenoble, where he was kept for 25 days in close confinement, with only two attendants. The victories of Suwaroff alarming the directory for the security of their captive, he was then removed to Valence and imprisoned in the citadel; and the order had been given to send him to Dijon, when he was released by death. Pius VI. was graceful in person, affable, accomplished, fond of learning and the arts, and by no means ignorant how to govern well. He undertook the drainage of the Pontine marshes, restored the Appian way and the port of Terracina, enlarged the Vatican museum, caused the publication of the splendid series of engravings known as the *Museo Pio Clementino*, adorned Rome with fountains and fine buildings, and attracted to his capital a number of learned men and artists from other parts of Europe. His administration was mild and liberal. III. Pius VII. (Barnaba Luigi Chiaramonti), born in Cesena in 1742, died Aug. 20, 1823. He entered the order of Benedictines at the age of 16, and after some years of study became lecturer on philosophy and theology to the novices at Parma and afterward at Rome. Pius VI. made him bishop of Tivoli, and in 1785 cardinal and bishop of Imola. On the death of that pontiff in exile, the conclave met at Venice, Rome being then in a state of anarchy, and after a session of several months chose Cardinal Chiaramonti pope, March 14, 1800. In the following July he entered Rome, which had previously been evacuated by the French; and in Aug. 1801, he signed a concordat with the first consul whereby Catholic worship was reëstablished in France as the state religion. In 1804 he went to Paris to crown Napoleon, passing several months there, and returning to Rome in May, 1805. The amicable relations thus apparently established were soon interrupted by the seizure by the French of the papal port of Ancona, and a demand from the emperor that his holiness should expel all Russians, Swedes, Sardinians, and Englishmen from his dominions. A long and acrimonious correspondence followed, the French meanwhile taking possession of Civita Vecchia and of all the ports on the Adriatic. The refusal of the pope to grant a divorce between Jerome Bonaparte and Miss Patterson, and a dispute concerning appointments to certain vacant sees in the kingdom of Italy, hastened the conclusion. In Feb. 1808, a French force under Gen. Miollis took possession of Rome; in April the emperor declared diplomatic intercourse at an end, and annexed the provinces of Ancona, Macerata, Fermo, and Urbino to the kingdom of Italy; and in May, 1809, the remainder of the Roman states were incorporated with the French empire, Napoleon declaring that he "deemed it proper for the security of his empire and of his people to resume the grant of Charlemagne." The pope replied to these outrages by a bull of excommunication (June, 1809). On July 6, between 2 and 3 o'clock in the morning, Gen. Radet forced an entrance into the Quirinal, and conveyed the pontiff to Grenoble, whence he was removed in 1811 to Savona. In June, 1812, he was taken to Fontainebleau. Here he was treated with great respect, and on Jan. 25, 1813, was persuaded, chiefly by the representations of several cardinals who were permitted to visit him, to sign a new concordat which tacitly gave up to the emperor the whole ecclesiastical states, and decided in favor of the civil power the long disputed question as to the papal veto on the appointment of bishops by the temporal authority. All the restrictions upon the freedom of his holiness were at once removed; but a little reflection showed Pius that he had been overreached, and on March 24, in a letter to the emperor, he retracted his concessions, expressing the humblest penitence for his weakness, and imploring the divine forgiveness. Napoleon took no notice of the letter, but after the disastrous campaign of Germany (1813) proposed to restore the provinces south of the Apennines if the pope would agree to a new concordat. Refusing to listen to any proposals until he had been restored to Rome, he was escorted to Italy in Jan. 1814; but the disturbed condition of affairs induced him to remain at Cesena until after the abdication of the emperor, when he made his entrance into Rome, May 24, 1814, in the midst of the liveliest demonstrations of popular satisfaction. For a short time during the Hundred Days he was again a fugitive, when his territories were invaded by Murat; but by the congress of Vienna all the states of the church, including the legations, were restored to him. The rest of his life was principally devoted to the domestic affairs of his dominions. He made great improvements in the police and courts of law, and through his minister Cardinal Consalvi did much toward the extirpation of banditti. He abolished every kind of torture, modified the powers of the inquisition, and confirmed the suppression of all feudal imposts, privileges, monopolies, and jurisdictions. He made new concordats with France and other states, reëstablished the society of Jesus (April 7, 1814), and condemned the carbonari. In his personal character he was modest, disinterested, and virtuous.—See Artaud de Montor, *Histoire de la vie et du pontificat du pape Pie VII.* (2 vols. 8vo., Paris, 1836), and Cardinal Pacca's "Historical Memoirs," translated into English by Sir George Head (2 vols. post 8vo., London, 1850). IV. **PIUS IX.** (GIOVANNI MARIA MASTAI FERRETTI), born in Sinigaglia, May 13, 1792. He is a son of Count Girolamo Solazzi. In his 11th year he was sent to a college at Volterra, and in 1808 went to Rome to pursue his ecclesiastical studies. During the French occupation he retired to Sinigaglia, but in 1814 returned to the capital, and in Dec. 1818 received holy orders. In 1823 he visited Chili in company with the apostolic delegate Monsignor Muzi, and passed two years at Santiago employed in preaching and instructing. Returning to Rome in Dec. 1825, he received from Leo XII. the appointment of president of the hospital of St. Michael, where he remained about a year and a half. In 1827 he was created archbishop of Spoleto. Here he founded an asylum for orphans, modelled somewhat after the plan of one over which he had presided in Rome before his mission to South America. During the disturbances of 1831 he induced 4,000 insurgents who had taken refuge in Spoleto to surrender to the papal authorities, and at the same time was intrusted *ad interim* with the civil administration of the provinces of Spoleto and Perugia. In 1832 he was transferred to the see of Imola, and in Dec. 1839 created cardinal, his appointment being reserved *in petto* until Dec. 1840. His residence at Imola was signalized by the foundation of a college for ecclesiastical students, asylums for orphans of both sexes, and a house for female penitents under the sisters of the Good Shepherd. On the death of Pope Gregory XVI. the conclave chose him pope, June 16, 1846, after a session of 48 hours, and on the next day he was proclaimed under the title of Pius IX. The election of a man of such known liberal sentiments was hailed with universal acclamation. On July 16 he published a general amnesty to political offenders, and immediately afterward applied himself with great diligence to reforming the administration, lowering the taxes, granting concessions for railroads and similar improvements, opening public offices to laymen, and stimulating manufactures and agriculture. He visited the hospitals and other public institutions in disguise, in order to detect whatever faults might exist in their management, and made his appearance in the streets on foot and without pomp. In Nov. 1847, he called together a council of state composed of delegates from the provinces. The enthusiasm excited by his liberal course extended throughout Europe and America; and in Dec. 1847, a remarkable meeting of sympathy was held by Protestant citizens in New York. The revolutions of 1848, however, soon made the Romans dissatisfied with the moderate concessions of the pope; and his unwillingness to take an active part in the Italian campaign against Austria, though he permitted a body of volunteers to march to the frontier, increased the popular discontent. He issued a proclamation, promising a constitution on a liberal basis, and summoned to the ministry the former French ambassador Count Rossi; but on Nov. 15 Rossi was assassinated at the door of the council chamber; on the next day the populace, the civic guard, the gendarmerie, the troops of the line, and the Roman legion besieged the Quirinal and forced the pope to accept a radical ministry; and on the 24th, having meanwhile remained a prisoner in his own palace, with no control over the civil administration and little or none over ecclesiastical affairs, he escaped, disguised as a simple priest, in the carriage of the Bavarian minister, Count Spaur, to Gaeta. Here he was received with great honor. The king and queen immediately sailed from Naples to meet him, and persuaded him to abandon his original purpose of accepting the hospitality of Spain. Declarations of attachment and sympathy, and presents of money, were poured upon him from all quarters of the world. He immediately issued a protest against the acts of the revolutionary government, and on Feb. 18, 1849, called upon the Catholic powers, particularly France, Spain, Austria, and Naples, for armed assistance. On the same day the Roman constituent assembly declared the inauguration of a republic and the deposition of the pope from his temporal authority. On April 25 a French force landed at Civita Vecchia and marched upon Rome, while the Austrians invaded the N. and the Spaniards the S. provinces. Rome capitulated July 1, and the government was intrusted to a papal commission, a consulta of state, a consulta for finances, and provincial councils. The pope returned to his capital in April, 1850. He declared a partial amnesty, but his progressive tendencies had been thoroughly checked, and he has since shown no disposition to rule as a constitutional monarch. Shortly after his restoration he published a brief restoring the Roman Catholic hierarchy in England, a measure which provoked a violent outburst of popular feeling, and led to an act of parliament forbidding the Catholic bishops to assume their titles. In 1854 he invited the bishops from all parts of Christendom to meet at Rome, and with their consent formally defined the doctrine of the immaculate conception to be a dogma of the Catholic faith. The ceremony took place in St. Peter's, Dec. 8. The other most important ecclesiastical acts of his pontificate have been the conclusion of concordats with Spain (1851), Baden (1854), and Austria (1855), and the foundation at Rome of English and American colleges for students of theology. At the time of the treaty of Villafranca, after the Italian war of 1859, it was proposed by the emperors of France and Austria to favor a confederation of the Italian states under the honorary presidency of the pope, but the project was soon abandoned. In the mean time a revolution had commenced in the papal territories (see PAPAL STATES), and on July 12 and Dec. 7, 1859, his holiness addressed notes to the diplomatic body, complaining of the part taken by Sardinia in these movements, and asking the assistance of foreign powers in behalf of his temporal authority. On Oct. 1 the Sardinian chargé d'affaires at Rome received his passport. On Dec. 2 the pope addressed a letter to the French emperor refusing to take part in the proposed European congress unless the emperor recognized the integrity of the Papal States as defined by the treaties of 1815. Napoleon replied by advising the surrender of the Romagna as the only possible solution of the Italian question, and the pope published, Jan. 19, 1860, an encyclical letter explaining his reasons for rejecting the emperor's advice. This was followed, March 26, by a bull of excommunication against all persons concerned in the invasion and dismemberment of his dominions, which was published with the usual formalities on the 29th. The events which have gradually stripped Pius IX. of nearly all his territory are mentioned in the article Papal States. The patrimony of St. Peter is still (May, 1861) guarded by French troops, but it is understood that Napoleon III. is willing to guarantee to the holy see no more than the city of Rome. A convention with Spain, concluded in Aug. 1859, engages Queen Isabella to send an army of occupation to the Roman states in case of the withdrawal of the French troops.

PIZARRO. I. Francisco, a Spanish adventurer and conqueror of Peru, born at Truxillo in Estremadura about 1471, assassinated at Lima, June 26, 1541. He was an illegitimate son of Gonzalo Pizarro, a colonel of infantry, and of Francisca Gonzales, a woman of humble condition in the town of Truxillo. He received little care from either of his parents, was taught neither to read nor write, and was employed in his early years as a swineherd. From this occupation he ran away and embarked with a crowd of other adventurers at Seville and sailed for the New World, which the discovery of Columbus had thrown open to Spanish ambition. In 1510 he was in Hispaniola or Hayti, and took part in an expedition to Uraba in Terra Firma, under the lead of Alonso de Ojeda, who on quitting the settlement in search of supplies left Pizarro in command of the colony. At a later period he was associated with Balboa in establishing the settlement at Darien, and was one of the first Europeans who set eyes on the Pacific ocean. After the death of Balboa he attached himself to the fortunes of Governor Pedro Arias, and was employed in several military expeditions. In 1515 he was sent with a small company across the isthmus to traffic with the natives on the shores of the Pacific; and when Panama was made the capital of the Spanish possessions in that quarter, he established himself in the neighborhood of that city on a tract of land which he cultivated by the labor of Indian slaves. After the lapse of a few years he formed an association with Hernando de Luques, a priest possessed of considerable money, and with Diego de Almagro, like himself a foundling and an adventurer who had earned the reputation of a gallant soldier, and uniting their funds, the three confederates fitted out an expedition for exploration and conquest along the southern coast. They purchased a vessel, and about the middle of Nov. 1524, Pizarro embarked at the head of 100 adventurers from Panama and sailed southward, leaving Almagro to follow in a smaller vessel as soon as it could be got ready, which he did not long after with about 70 men. Neither voyage was successful, and after running for several hundred miles down the coast of New Granada, and sustaining terrible hardships and losing a number of men in their attempts to penetrate the interior, both commanders returned to the isthmus with a moderate quantity of gold which they had obtained from the natives. They brought intelligence of the existence of the rich empire of Peru, and after a long controversy with the governor, Pedro Arias, succeeded in getting permission to make a second attempt. So many of their men had died of sickness and hardships in the first expedition, that only 160 could be mustered for the second. Their first exploit was to plunder a small village on the river San Juan, where they got considerable booty in gold, with which Almagro returned to Panama to beat up recruits, while Pizarro established himself on the coast and awaited reënforcements. Almagro returned with 80 men, but the numbers and spirit of the Peruvians were so formidable that the force of the adventurers was still deemed insufficient for the conquest, and Almagro was again despatched to Panama for reënforcements, while Pizarro with his followers continued to explore the coast. The governor of Panama refusing to grant any further assistance to the enterprise, Pizarro, after various adventures during which he obtained much knowledge of the country, sailed back to Panama, and went thence to Spain to ask for aid from the royal government, taking with him as vouchers several natives of Peru, a few llamas, and many articles of gold and silver of Peruvian manufacture. He reached Seville early in the summer of 1528. Immediately on his landing he was arrested and put in prison for debt contracted in America; but the king indignantly ordered his immediate release, and received him at court with distinguished favor; and on July 26, 1529, a *capitulacion* or commission was granted to him conveying the right of discovery and conquest in Peru, with the title and rank of governor and captain-general of the province, together with those of *adelantado* and *alguacil mayor* for life and a salary of 725,000 maravedis. He was in fact to have nearly all the authority of a viceroy. On his part he agreed within 6 months to raise and equip a force of 250 men, and to embark without delay for the conquest of Peru. With a small force partly gathered in Spain, and accompanied by 4 of his brothers, Pizarro recrossed the Atlantic in Jan. 1530, and just a year later sailed from Panama with 3 vessels, 180 men, and 27 horses on his final and successful expedition against the empire of the tions. (For an account of the conquest, see Peru.) During nearly the whole enterprise there had been much dissension between Pizarro and Almagro, the latter complaining justly that his services were not properly rewarded, and that Pizarro had appropriated to himself an undue share of the honors and emoluments of their successful undertaking. The quarrel had at length broken out into civil war, in which Almagro was captured and put to death. The contest was continued by his friends, headed by Diego Almagro, his son by an Indian woman. This faction at length formed a conspiracy to assassinate Pizarro, and on Sunday just after dinner attacked him in his palace and killed him in a desperate affray, in which three of their number fell beneath his sword. He was about 70 years old at the time of his death, and left two children by a daughter of the inca Atahualpa. His descendants, bearing the title of marquis of the conquest, are still to be found at Truxillo in Spain.—Pizarro was tall, well formed, with a not unpleasing countenance, a soldier-like bearing, and a commanding presence. Though grasping in the acquisition of money, he was liberal in its use, and not only gave largely to his friends and followers, but expended most of the vast treasures of which he plundered the Incas in public buildings and schemes of improvement. Lima and several other cities were founded by him. He had never been taught either to read or write, and to the day of his death was ignorant of both those accomplishments. Though bold in action and not easily turned from his purpose, he was so slow in coming to a decision that he had an appearance of irresolution which was foreign to his character. He had formed the habit of saying "No" to every request, in order at leisure to consider the matter and grant what was expedient. He was cruel, cunning, and perfidious, and his merits seem to have been courage, constancy, and fortitude. II. Gonzalo, one of the conquerors of Peru, youngest brother of the preceding by the same father but another mother, and also illegitimate, born at Truxillo about 1506, executed at Cuzco in 1548. He entered early on the career of a soldier, and soon distinguished himself by his skill in martial exercises, so that when he came to the new world he was esteemed the best lance in Peru. He was an excellent guerilla chief, but had neither the military nor the civil capacity of Francisco. In 1540 he was appointed governor of Quito, and organized and led an expedition across the Andes which resulted in the discovery of the head waters of the Amazon and the descent of that stream to the ocean by Orellana, one of his officers. After the assassination of his brother he raised an army and rebelled against Blasco Nuñez, the new and unpopular viceroy who had been sent from Spain. He was warmly supported by the bulk of the colonists and many of the royal soldiers, and rapidly drove the viceroy from Lima, and on Jan. 18, 1546, defeated him in a pitched battle near Quito in which Nuñez was slain on the field. This victory gave Pizarro for a while the undisputed mastery of Peru. But in the following year he was attacked by the royal forces under the direction of Pedro de la Gasca, who had been sent from Spain with full authority to suppress the rebellion. After various encounters Pizarro was deserted by some of his followers, and was defeated, taken prisoner, and beheaded. III. Hernando, elder brother of the two preceding and one of the conquerors of Peru, born about 1465, died about 1565. He was the legitimate son of Colonel Pizarro by a lady of good family, was well educated, and at an early age was taken by his father to the wars in Italy, where he served under the Great Captain Gonsalvo de Cordova. He played a distinguished part in the conquest of Peru, and in 1533 was selected by his comrades as their representative to proceed to Spain with the royal share of the booty they had collected, and to ask the king for additional grants of privileges and honors. He arrived in Spain in Jan. 1534, and met with a gracious reception from the king, who complied with all the requests of the conquerors of Peru, and made their emissary a knight of Santiago and empowered him to equip an armament at Seville and take command of it. In a short time Hernando crossed the ocean with one of the largest and best appointed fleets that had yet sailed from Spain for the new world. Soon after his arrival in Peru he was appointed governor of Cuzco, which he defended for 5 months against a great host of Indian warriors. Subsequently he became involved in hostilities with Almagro, whom he had always opposed, and was taken prisoner, but spared by his rival, who finally set him at liberty. A few months later Almagro fell into the hands of Hernando and was put to death by his order. In the following year Hernando went to Spain, carrying with him a great quantity of gold, to which he trusted to obtain favor at court and rebut the charges which had been preferred against him by Almagro's friends. He was coldly received, and, though no formal sentence was pronounced against him, was imprisoned for 20 years in the fortress of Medina del Campo, from which he was dismissed in 1560 when nearly 100 years old.

PLACENTA. See Embryology.

PLACENTIA. See Piacenza.

PLACER, a middle co. of Cal., bordering on Utah, and watered by the Bear and branches of the American river; area about 1,000 sq. m.; pop. in 1860, 13,270. Its surface is mountainous toward the E., and it contains a large extent of land suitable for agriculture, and is also very rich in gold ore, having furnished $7,000,000 in 1858. In the same year the county produced 108,000 bushels of wheat and 100,000 of barley. There were 2 grist mills and 23 saw mills, 11 of which were propelled by steam, and the aggregate product of lumber was 35,000,000 feet per annum. Capital, Auburn.

PLACOIDS, a division of cartilaginous fishes in the old system of Agassiz, including the sharks and rays, characterized by a skin covered irregularly with enamelled plates, or studded with rough osseous points sometimes furnished with little hooks, and resembling the peculiar surface of shagreen. They are among the highest of fishes, approaching reptiles, and many of them are viviparous. (See COMPARATIVE ANATOMY, FISHES, and ICHTHYOLOGY.)

PLAGIOSTOMES (Gr. πλαγιος, transverse, and στομα, mouth), a sub-order of cartilaginous fishes, including the sharks and rays, in some respects the most highly organized of their class; they correspond to the selachians of Cuvier, and to the placoids of Agassiz; they are few in number in the present creation, but with the ganoids (sturgeons, &c.) were by far the most abundant in past geological epochs, these two sub-orders being the only members of the class found below the chalk. The centre of their vertebral column is usually more or less ossified and divided into separate vertebræ, and even when it forms a continuous *chorda dorsalis* the divisions are indicated by transverse partitions; the skull is united to the spine by a joint with a conical cavity, and the former is a simple cartilaginous capsule, without sutures, having a separate cartilaginous arch which performs the office of upper jaw; the mouth is arched, very wide on the lower surface, and at some distance from the snout, which is much developed for the accommodation of the large nasal capsules; the teeth are in numerous rows, the inner coming forward to replace those worn away by use; the branchial sacs are separated, with 5 or more distinct openings on the sides or lower parts of the body; the gills consist of membranous folds or plane surfaces, without the pectinated arrangement of osseous fishes, and with a pseudobranchia; there is no swimming bladder; the scapular arch is detached from the head, and the ventrals are abdominal; on the upper surface of the head, behind the eyes, is a pair of spiracles, communicating with the pharynx; the skin is covered with hard rough grains or scattered spines; in the arterial bulb are from 2 to 5 transverse rows of semilunar valves; the intestine has a spiral valve; the optic nerves do not decussate, but are connected by a commissure, and there is no arterial plexus between the layers of the choroid coat of the eye. The secreting reproductive organs communicate with the ureters, and end in a rudimentary process in the cloaca; the claspers are present as appendages to the posterior edge of the anal fins, fissured toward the end, and communicating with a cæcal subcutaneous sac, well lubricated with mucus; the ovaries are smaller than in osseous fishes, and the ova very few; some genera are viviparous, others oviparous, and others ovo-viviparous.

PLAGUE (Gr. πληγη, a blow), an aggravated malignant fever, endemic in the East, and frequently epidemic. By the old writers the words *pestis* and *pestilentia*, the synonymes of plague, as well as the corresponding Greek word, were used in an exceedingly loose sense, and must be taken as meaning nothing more than an epidemic fever. True plague is a contagious fever characterized by an eruption of carbuncles and buboes. Formerly plague occasionally prevailed in many places of northern Europe. Previous to its last visitation in 1665, it invaded England, according to Sydenham, every 30 or 40 years. Marseilles suffered from it in 1720, Moscow in 1771 and 1772, and some points in the Neapolitan dominions as late as 1815 and 1816. The celebrated "black death," which ravaged all Europe during the 14th century, appears to have been the oriental plague. As in all severe epidemics of the disease, at its commencement many of the patients died previous to the development of the peculiar eruption; but the general occurrence of carbuncles and buboes is sufficiently authenticated. It derived its name from the gangrenous eschars formed by the carbuncles, or perhaps from the petechiæ which accompanied the disease.—A report made to the French academy (*Rapport à l'académie royale de médecine sur la peste et les quarantaines*, &c., Paris, 1846) says: "1. At present the countries where the plague still originates are in the first place Egypt, afterward Syria and the two Turkeys. It is probable, however, that the plague may be developed without importation in the regencies of Tripoli, Tunis, and in the empire of Morocco. 2. In those countries the conditions which determine and favor its development are the habitation of alluvial or marshy grounds; a hot, moist atmosphere; low, badly aired, and crowded houses; the accumulation of a great quantity of animal and vegetable matters in a state of putrefaction; a scanty and unwholesome diet; great moral and physical destitution; the negligence of the laws of public and private hygiene. 3. Sporadic plague does not seem to be transmissible. Epidemic plague is transmissible both in the localities where the plague is raging and without them. 4. It is transmitted by means of miasmata given out by the bodies of the sick; these miasmata, in close and ill ventilated places, may create centres of pestilential infection. No rigorous observation has shown the transmissibility of the plague by simple contact with the infected. New experiments are necessary to determine that it is not transmissible by the goods and wearing apparel of the infected. It results from the observations made at the lazarettos for more than a year that merchandise does not transmit the plague." The period of incubation in plague would seem in no case to be beyond 8 days. The course of the disease varies very much in different cases. Sometimes the local symptoms first show themselves, and the fever which follows is comparatively mild; at other times the patient is rapidly overwhelmed by the violence of the constitutional disorder, and dies without the appearance of carbuncles or buboes; between these extremes, and tending to one form or the other, the disease presents every grade of variety. In its milder forms small spots like flea bites first make their appearance, especially on the parts of the body exposed to the air; these enlarge, become dusky, and are covered by vesicles or phlyctenæ filled with a dark-colored fluid. The base of the spots is hard; it becomes black, forming a gangrenous eschar with a circumference of an inch or an inch and a half in diameter; these are the carbuncles. This process is attended with more or less fever, which as the eschar becomes detached gradually subsides. Often consequent upon the appearance of the carbuncles, glandular swellings form, commonly in the groins or armpits, more rarely in the neck. These buboes, as they are formed, occasionally disappear without suppuration, more generally after a time pus is formed, sometimes healthy, sometimes thin and sanious. Cases in which buboes appear are attended with a higher grade of fever and with profounder depression of the vital forces; headache, restlessness, chills, and vertigo are commonly present; the eyes are red and muddy, the tongue coated, the skin hot and dry; the pulse small, weak, and frequent; petechiæ are frequently present. The duration of the disease varies. In the commencement of severe epidemics cases have been related in which the patients have died within 24 hours; in most instances, however, it continues from one to two weeks. In severe epidemics the majority of the patients die, and when recovery takes place convalescence is tedious. Morbid anatomy hitherto has added nothing to our knowledge of the disease; the blood is found to be altered and fluid, but no appearances have been noted which can be deemed characteristic.—Of the treatment of plague we know little; like other contagious exanthems, it probably runs a prescribed course which cannot be materially shortened, and perhaps in the present state of our knowledge it would be wisest in most cases to limit our efforts to the local treatment of the carbuncles and buboes, supporting the patient's strength, and placing him under as favorable hygienic circumstances as possible.

PLAICE. See FLOUNDER.

PLAINS. Two great divisions have been recognized of those portions of the earth's surface not covered by water, viz., mountains and plains, making the latter term include hilly and undulating countries and broad tracts, at whatever elevation they might be, so that the irregularities of their surface could not be denominated mountains. The geographer Buache of the French academy introduced a distinction between plains of great elevation and those lying near the level of the sea, calling the former plateaux and the latter plains or lowlands. This distinction was adopted by Humboldt, and some have restricted the term plateaux to high lands maintaining a general level, which is more or less broken up by hills, while those of a plane surface presenting around their margins abrupt descents are called table lands. Various other names designate the different kinds of plains or those of different countries.—Deserts are sandy and rocky wastes occupying immense tracts of the low lands of the globe. They abound especially in Africa and Asia, and are much less frequent and extensive on the American continent. They occur in general in regions which the prevailing winds reach after they have swept over broad tracts of mountain lands and been deprived of the moisture they carried with them. The plains of western Peru, lying under the range of the Andes, are the principal deserts of South America, and in North America other sterile tracts of vast extent and of similar features are met with on both sides of the Rocky mountains. The great African desert (see SAHARA) extends from the W. coast of Africa to the Red sea, a distance of 2,500 m., and over a width of 1,000 m. Parts of this desert are bare ledges of rock, upon which the traveller may pass for days together without seeing anything beside the hard pavement beneath and the sky above. To these succeed oceans of sand, with which in many places are intermixed such quantities of salt that the surface is white with it as if covered with ice. Beyond the Red sea the range of desert land overspreads nearly all of the Arabian peninsula, a considerable portion of Asia Minor, and may be traced through Persia, Tartary, and the great central plateau of Asia, extending thus in one almost continuous band of varying breadth from the Atlantic ocean to the borders of China. The extent of these lands in northern Africa and southern Asia, not reckoning the oases or fertile tracts included within their limits, was estimated by Humboldt to exceed the whole area of Europe, or about 500,000 square leagues.—Nearly the whole of southern Africa is an extensive though not very elevated table land, which extends 6° or 7° N. of the equator, and terminates in the highland of Senegambia on the N. W. and on that of Abyssinia in the N. E. On the E. and W. this table land is bounded by mountain chains which divide it from the lower plains bounded by the Atlantic and Indian oceans. Southward the plateau dips to the maritime plains by successive steps composed of long narrow plains called *karroos*, which in the dry season are arid deserts, but after the setting in of the autumnal rains soon become covered with verdure and with a splendid flora. The great plains of the interior are generally grassy, with a vegetation very different from the tropical vegetation of the sea coast. North of Lake Ngami the country is a dead flat for hundreds of miles, interlaced by a labyrinth of rivers with their tributaries and numerous intercommunicating branches.—The interior of Australia, so far as it has been explored, consists chiefly of vast flats, in which the rivers become stagnant in a wilderness of gigantic reeds, and the traveller scarcely finds a knoll high enough to raise him above the waters in the season of floods. Here are found wide tracts of thick herbaceous brushwood, which afford no sustenance of any kind to those who traverse them. Long droughts, to which the country is peculiarly subject, and which last sometimes for years, dry up the rivers and lakes, and convert these plains into deserts from which sweep hot winds raising the temperature of the coast regions between lat. 25° and 35° S. to even 130° in the shade. The falling of the rains, however, speedily converts these dusty wastes into verdant pastures.—Central Asia is a region of immense mountain chains supporting table lands of great extent. The northern parts of the same continent and of Europe present over a range of more than 6,000 m. a succession of broad plains, covering the greater part of Siberia, a large part of Russia, Germany, and Holland. On this range, from the Pacific to the Atlantic, are no elevations exceeding a few hundred feet. These plains in Siberia and Russia are called steppes, and large portions of them are rich pasture lands, without trees, and much resembling the prairies of the Mississippi valley.—The American continent, North and South, is eminently a land of plains. They form full two thirds of the whole surface of the country, extending on the Atlantic side from one extremity of the continent to the other, with only occasional interruptions by mountain ranges of little extent. In South America are distinguished three great regions of plains separated from each other by low ranges of mountains, which run from the Atlantic coast toward the Andes. The northern of these regions, having an area of 260,000 sq. m., comprises the valley of the Orinoco and its tributaries, and the elevation of this great territory nowhere exceeds 800 feet above the sea level. So smooth is the surface that over hundreds of square miles the land is almost as unbroken by any unevenness as the water itself, and the rivers are so sluggish that their current is diverted in any direction by light winds. This is the region of the *llanos* (Lat. *loca plana*). In the dry season the ground is parched and barren, and clouds of fine dust and sand incessantly rising fill the air. The grasses, which in the rainy season suddenly spring up and grow to the height of 4 feet, are withered and dissipated in dust. Naked stems of the palm scattered over the plains, seen through the obscure atmosphere, appear like masts of ships at sea; and as the same forms continually present themselves to the advancing traveller, he is painfully impressed with the sense of the boundlessness and dreariness of these solitudes. But as the vegetation comes forward with the return of the rains, the plains are soon overrun by vast herds of horses and wild cattle, which then find a rich pasturage; and from the jungles of the river banks, to which they had retired during the drought, the great serpents and alligators make their appearance and overspread the plains. The only interruptions to the dead level of the surface, beside the depressions of the beds of the rivers and creeks, appear to be occasional banks of limestone or sandstone called *bancos*, standing 4 or 5 feet above the general surface, flat at the top, and several leagues in length. Slight undulations, called *mesas*, imperceptible to the eye, are indicated by the water courses which are turned by them in different directions.—The plains of the Amazon extend up the course of that river and its branches to the Andes, and include, with all the waters they enclose and some ranges of hills, an area of 2,340,000 sq. m. About one third of this vast territory is covered with dense forests, the principal portions of which have never been penetrated; and so luxuriant is the vegetation and enervating the climate, that to reclaim any considerable extent of these wilds is a task almost beyond the ability of man. From their wooded character they are termed *selvas;* but open tracts like the llanos are scattered among the forests, and numerous broad rivers occupy large areas and afford the only means of gaining access to the distant interior.—The plains of the southern portion of South America, lying beyond lat. 15° S., are termed *pampas*, from an Indian word signifying a flat. They resemble the steppes of Russia, being open grass-covered tracts of vast extent, interspersed with sterile portions of sandy and stony character. Their total extent from N. to S. is about 1,800 m., and from E. to W. from 300 to 900 m. On the N. they reach the region of tropical productions, and at the extreme S. their surface is in many places concealed beneath the never-melting ice and snow of these frozen latitudes. Across their range from the coast to the Andes three belts are recognized in their northern division, distinguished from each other by their peculiar productions. The first is strongly marked by its singular growth of tall thistles succeeded by clover. The former come forth with wonderful rapidity in the early summer, shooting up to the height of 10 or 11 feet, and sending forth a profusion of rich blossoms. So close are the stems, that even if unarmed with their prickles they would still present an impenetrable barrier. As the summer passes away this vegetation dies down, and luxuriant crops of clover spring up, and invite the return of the countless herds of cattle which were expelled by the thistles. To the west of this is a belt of plains covered with long grass, which from season to season undergoes little change except as the green of summer changes to the brown hue of winter, and this gives place to the verdure of the succeeding spring. Beyond this is a region of more elevated plains lying along the range of the Andes, and covered with low trees and shrubs, all evergreens.—The plains of North America, while no less extensive than those of the southern part of the continent, are distinguished from them by greater diversities of level, which, together with superior advantages of climate, render the country far better adapted to the necessities of man. Excepting the parts covered by the Rocky and Alleghany mountains and their spurs, all the rest are plains uninterrupted by mountain elevations. Near the mountains the surface is hilly and more or less broken; but receding from the Alleghanies westward it gradually assumes the distinctive character of plains, which are developed upon a grand scale in the boundless prairies of the north-west, and in the barren territories commonly known by the name of plains which stretch away from the prairie region in the states of Arkansas, Missouri, and Kansas to the foot of the Rocky mountains. Throughout these immense territories the differences of level are sufficient to produce a steady flow in the mighty rivers, not so rapid as to obstruct their navigation, but sufficient to insure salubrity to the country by a healthy drainage; and thus is secured a system of easy intercommunication between all sections of the country, unsurpassed in importance by any similar system in the world. In the first volume of the geological report of Iowa Prof. James Hall has presented a full account of the north-western prairies. The region they occupy is the western part of Ohio, nearly the whole of the states of Indiana, Illinois, and Iowa, the southern part of Michigan, the northern part of Missouri, and portions of Kansas and Nebraska, in which, near the meridians of 97° and 100° W., they gradually pass into the arid and desert plains. Throughout this territory a great sameness exists in the varieties of the topography, the vegetable productions, the soil, and geological features. The surface is drained by streams which commence in almost imperceptible depressions of the high prairie, and flow in beds and valleys of gradually increasing depth between vertical walls of limestone or sandstone, through the horizontal strata of which the current has in past times made its channel. What are called bottom lands lie between the rocky bluffs and the stream, and upon the Mississippi and the Missouri these attain in places a width of 6 to 8 m.; they are, however, often wanting entirely, the bluffs on each side coming close to the river banks. On the upper Mississippi the bottom lands are in general well wooded, but along the state of Missouri they spread out into open prairies. These low or wet prairies are distinguished from the high or rolling prairies, which form the general upper level of the country upon the summit of the bluffs. The elevation of these above the rivers is very variable. Near Prairie du Chien in W. Wisconsin, it is about 400 feet above the Mississippi, and the bluffs themselves present a vertical face of about ¼ of this elevation. At Cairo in S. Illinois, the upper surface is from 100 to 250 feet above the river, or 400 to 550 feet above the sea level. In the central portion of the state, near the Illinois central railroad, the average elevation is from 600 to 750 feet above the sea, and near the northern border of the state this increases to 800 or 900 feet, and some of the highest swells of the prairie are 1,000 feet high. In S. Wisconsin the more elevated portions of the prairie are about 1,100 feet above tide water. In Iowa the *plateau du coteau des prairies* of Nicollet, dividing the waters of the Mississippi from those of the Missouri, is from 1,400 to 1,600 feet above the sea. On the head waters of the Illinois and Wabash, and S. and W. of Lake Michigan, the prairies are very level and smooth, and are termed flat. Elsewhere the surface is undulating and broken by the depressions of the streams, and they are known as rolling prairies. The depressions where there are no streams are often 50 feet below the mean level, and in the bottom the soil is wet and marshy and forms "swales" or "sloughs," which render the roads almost impassable. In these places the grass grows very rank and tall, but upon the upper and drier surface the natural growth is finer and the sod dense and closely interwoven. A great variety of flowering plants are interspersed among the grasses, and during the summer the whole surface of the prairies is gaily decked with the bright colors of their blooms. The characteristic herbs, as described by Prof. Gray in a paper on the "Flora of the Northern States," published in the "American Journal of Science" (2), xxiii. p. 397 (1857), would seem to be *compositæ*, especially helianthoid *compositæ*, of many species. Among the various plants named are many recognized as cultivated ornamental garden flowers. Trees are met with upon the prairies under peculiar circumstances of moisture and soil, in scattered groups, called groves, or along the larger streams, or occasionally on low rocky ridges, which are sometimes met with. West of the Mississippi they become less frequent, and near long. 98° W. they disappear altogether. The soil of the prairies is remarkable for its finely comminuted condition. It is generally free from stones, though in some localities bowlders or fragments of rock are found upon the surface and scattered through it. In the swales and in some of the bottom lands the rich black vegetable mould is very deep, but on the upper prairies its depth is usually from one to two feet. The subsoil is almost invariably an argillaceous loam, more or less mixed in its lower portions with sand and occasional pebbles. The total thickness of clay, sand, and loam amounts in some places near the larger rivers to 200 feet; but the rock is often found in other places very near the surface; its immediate cover consists of layers 2 or 3 feet thick of angular fragments. Water is generally found in the sandy stratum 15 to 30 feet below the surface. Throughout the prairie region the underlying rocks are soft sedimentary strata, especially shales and impure limestones. Most of these on exposure disintegrate readily and crumble to soil, and the whole soil of the prairies appears to have been produced from such materials not removed far from their parent beds. To the finely comminuted condition of these materials Prof. Hall ascribes the treeless character of the prairies. Where such soils are found in other portions of the West, covering tracts of limited area even in thickly wooded districts, they are commonly without trees, and, as is the case with the prairies themselves, no evidence is found in the form of ancient trunks buried in the soil that trees ever grew in these localities.

PLANCHÉ, JAMES ROBINSON, an English dramatist, born in London, Feb. 27, 1796. In 1818 he produced successfully at Drury Lane theatre a burlesque, entitled "Amoroso, King of Little Britain." In 1826 he travelled in northern Europe, publishing on his return "Lays and Legends of the Rhine," and in 1827 visited Germany again. In 1828 he produced at Drury Lane his 55th and perhaps his best dramatic work, "Charles XII." In 1830 he was elected a member of the society of antiquaries; in 1834 wrote the "History of British Costume;" in 1838, "Regal Records;" and in 1852, "The Pursuivant of Arms, or Heraldry founded upon Truth." In March, 1854, he was appointed rouge croix pursuivant of arms. Down to 1857 he had written 200 pieces for the stage.

PLANCHE, JEAN BAPTISTE GUSTAVE, a French critic, born in Paris, Feb. 16, 1808, died Sept. 18, 1857. He was educated at the Bourbon college, and became in 1831 a contributor to the *Revue des deux mondes*. For a few months he was attached to the staff of the *Journal des débats*, and in 1836 assisted Balzac in editing the short-lived *Chronique de Paris*. His critical severity made him the dread of artists and authors, while his slovenly personal habits caused him to be styled the "Diogenes of literature." Having inherited property from his father, he went to Italy about 1841, and devoted 5 years to studying the masterpieces of Italian art. On his return home in 1846, he published the results of his observations in biographical and critical essays on the Italian masters. His various essays have been collected and published by himself, 11 volumes in all.

PLANCK, GOTTLIEB JAKOB, a German theologian, born in Nurtingen, Würtemberg, Nov. 15, 1751, died in Göttingen, Aug. 31, 1833. He was educated at Tübingen, and in 1784 became ordinary professor of theology in Göttingen. Through his instrumentality, and in particular through his essays upon the history of the church and its doctrines, he gave a decided impulse to the study of theology in that university. His principal work is the "History of the Origin, the Changes, and the Development of our Protestant System" (6 vols., Leipsic, 1781–1800); and this was continued in a work published after a long interval under the title of "History of Protestant Theology from the Concordiæ Formula to the Middle of the Eighteenth Century" (Göttingen, 1831).—**HEINRICH LUDWIG**, his son, born in Göttingen, July 19, 1785, died Sept. 23, 1831, extraordinary professor of theology at Göttingen, wrote, among other works, "New Revelation and Inspiration" (1817), and a "Short Scheme of the Philosophic Doctrines of Religion" (1821).

PLANE, a surface such that a straight line joining any two points in it will lie wholly in that surface, or such a surface as may be conceived to be generated by a straight line revolving around another straight line at right angles to it. Plane geometry treats of the nature and properties of plane figures; plane trigonometry of plane triangles, or those which lie entirely in the same plane.

PLANE, a tool used by carpenters and joiners for smoothing down the surface of wood, and also for cutting it into shape corresponding to that of the cutting edge of the plane iron. Planes of the former kind, which form only flat surfaces, are called bench planes or surfacing planes; and the latter are grooving or moulding planes. They are all formed of a solid block of hard wood, called the stock, from the upper to the lower side of which is cut a wedge-shaped hole descending forward in ordinary planes at an angle of about 45°. The plane iron, which is like a chisel in shape, is placed in this opening and temporarily secured by a wooden wedge. When properly fixed and the plane is pushed forward on a board, the edge of the iron enters to a depth equal to its projection beyond the sole of the stock, and takes up a shaving which passes up the opening through the stock and is thrown out at the top. The width of the plane iron is from 2 to 8½ inches in nearly all the bench planes, which differ from each other chiefly in the length of the stock. Short planes of 5 to 8 inches are called smoothing planes, and are used mostly for giving a smooth finish to the work. Jack planes are from 12 to 17 inches in length, and are used for the rougher work. Planes of from 2 feet to 6 feet in length are known as jointers, and serve to give straightness and accuracy to the surface. In the grooving or moulding planes the sole is grooved along its whole length to correspond with the irregular outline of the edge of the plane iron; and as each plane thus cuts only its own figure, a variety of these planes are required for the diversity of mouldings, beads, grooves, ornamental edges, &c., with which joiners give a finish to their work. One form of these planes is constructed for shaping the narrow strips of which window sashes are made, each size of sash requiring its appropriate plane. (See PLANING MACHINE.)

PLANE TREE, a tree frequently planted for shade, belonging to the natural order of *platanaceæ* or planes, exogens seemingly related to the breadfruits, with deciduous sheathing stipules, flowers in globose heads, watery juice, albuminous embryo, and minute plumule. The leaves of the planes are alternate, palmate, lobed, with sheathing deciduous stipules and petioles hollow at base concealing the young leaf buds; flowers monœcious, very small, both kinds without calyx or corolla, crowded into globular aments; stamens numerous, mixed with subclavate scales; ovaries numerous, obconic or narrowly clavate, crowded and mixed with flattened scales; style elongated, awl-shaped, with the stigma on one side and near the apex; fruit a nut 1-celled and 1-seeded; seed pendulous, embryo long, tapering, lying in the axis of very thin albumen.—The oriental plane (*platanus orientalis*, Linn.) grows to the height of 60 to 80 feet; its leaves are 5-lobed, palmate, the divisions lanceolate, sinuated, stipules nearly entire; the flowers appear in May. It is a native of the Levant, and has long been in cultivation. It is justly considered one of the noblest trees of the East, on account of its massive trunk and wide-spreading branches. The bark is smooth and of a whitish gray color, scaling off every year in large patches; the branches are crooked and zigzag at the joints; the leaves large and on long petioles, cut into 5 deep-pointed lobes; the upper surface is smooth and of a shining green, the under surface paler and somewhat downy at the angles of the veins. The flowers are so small as to require a magnifying glass to distinguish them; they grow in the form of balls, which appear before the leaves in the spring, the seeds ripening in the autumn, but remaining as balls till the succeeding spring, when they open and are dispersed by means of the bristly down which surrounds them; they are small and very light, and are in reality little nuts, structurally considered. This species is of very rapid growth and attains to great age. Its geographical distribution is wide, being found in Asia Minor and Persia, and extending as far south as Cashmere. As it ascends into the mountainous regions it degenerates into a mere shrub, as on the Caucasian range. It is seldom gregarious, and the largest specimens are found in rich soils near water. It was a favorite among the ancients, and is early mentioned in Grecian history. Among the Persians it bears the name of *chinar*, and avenues and rows of it are planted in their gardens. In parts of Asia where timber is scarce the oriental plane is much employed in carpentry, joinery, and even ship building. Its wood when dry weighs 40 lbs. 4 oz. per cubic foot; it is of a yellowish white till the tree attains considerable age, after which it becomes brown mixed with jasper-like veins, and when polished it is of much beauty.—The occidental plane (*P. occidentalis*, Linn.) is the largest, loftiest, and noblest deciduous tree in America, having a grand columnar trunk, gradually diminishing upward, which gives the base great stability. Its leaves are on stout footstalks 2 or 3 inches long, very downy and grayish green at first, but becoming smooth and purplish; when first expanded they are covered with a cottony down, which disappears and the upper surface becomes perfectly smooth, though some remains of it may be seen on the lower surface; when about to fall they turn to a pale yellow. As a shade tree none is more pleasing, especially when in vigorous foliage; its branches, shooting out in a horizontal manner, finally take a direction toward the ground; its clean and whitish gray trunk and the pendent aments are conspicuous, and its entire contour, especially if the specimen have ample room to grow, renders it at all seasons attractive. In New England this species is most commonly called the buttonwood and sycamore, the latter a name belonging to an entirely distinct tree. In Canada it is called the cotton tree. From that region its range southward is beyond the Mississippi and westward from the Atlantic to the extreme western states. Like the other species, it prefers a rich, cool, and moist soil, flourishing especially on the banks of the Ohio river and its tributaries. The buttonwood is seldom attacked by any insect, but a remarkable disease has prevailed for about 20 years past, destroying its capacity to make full and perfect foliage, in consequence of which its limbs have perished and the tree in some instances died. This epidemic seems to have been general, and to be the result of badly ripened wood occasioned by the lateness of the spring growth of the young shoots and the early coolness of the autumn. In some instances, fine old trees very much injured have nearly recovered and produced their balls after several seasons of previous failure. Something similar occurred to the species in the parks of England more than 50 years ago, but there it was attributed to a late spring frost. The buttonwood has been strongly recommended for artificial plantations in order to raise a supply of firewood, for which it is very suitable, especially when used in stoves. As timber it is not much esteemed, being very perishable when exposed to the weather, though it is sometimes sawed into joists and other lumber. The wood of the stem is of an agreeable faint red color, becoming deeper in that of the roots; this, if permanently fixed by artificial means, might afford a material for ornamental purposes.—The Californian buttonwood (*P. racemosa*, Nuttall) is a remarkably distinct species; the leaves are divided more than half way down into 5 sharp-pointed, lanceolate portions, of which the 2 lowest are the smallest; all the divisions are quite entire; 2 of them in small leaves are suppressed, thus producing a leaf of only 3 parts. The young leaves, clad in a brown, pilose tomentum, feel like a piece of stout woollen cloth. The catkins are in racemes, 3 to 5 in number, with remarkably long styles persistent on the ripe balls; and a raceme with the full-grown balls measures 9 inches. The tree laden with these long pendulous racemes, each bearing so many balls at the distance of about an inch from each other, presents a very unusual appearance. The wood is thought to be superior to that of the common species, harder, more durable, and less liable to warp. In general character the tree resembles the oriental plane more than it does the common buttonwood.—The planes are readily raised from seed and propagated by layers and by cuttings. The surest way is by seeds, which should be separated from the balls by beating or by the hand. They should then be rubbed to make them clear of the wool. They can be gathered in March and sowed in the spring broadcast, very thick, in a rich seed bed of light and carefully prepared mould. When the plants first appear they should be screened from the heat of the sun, when a year old transplanted into rows 3 feet asunder, and when 4 or 5 years old transplanted and set for shade, ornament, or fuel. Cuttings put in at autumn will root, but not readily. Layers may be made either in autumn or spring; they root well, and make strong shoots the first year, ready for removal.—Except for timber and shade, the planes are of no known utility.

PLANER TREE. See Elm.

PLANET. See Astronomy.

PLANING MACHINE, a machine for planing boards and other lumber by mechanical power. This is an old invention, and was long since brought to a state of perfection nearly limiting the more recent improvements to its adaptation to mouldings and other ornamental work. Among the earliest attempts to substitute machinery for the hand plane was that of Gen. Bentham of England, who procured a patent in 1791. This was merely an application of mechanism to drive a slightly modified hand plane. Though there was too little originality in the invention to prove successful, it was experimentally used, and by demonstrating its own defects led to the invention of a machine patented by Mr. Bramah in 1802, which was placed in the royal arsenal at Woolwich, where it did good service for many years. Bramah's machine performed its operation by the rotation of a vertical spindle, carrying at its lower extremity a horizontal wheel, the rim of which was furnished with 28 cutters or gouges, which were followed by a plane also attached to the wheel. Thus the rough surface of the board was trimmed and left perfectly smooth as it was carried by suitable mechanism from end to end, under and in contact with the cutters and plane.—Though American patents were occasionally granted for these machines from the year 1800 to 1828, but little interest was felt in the invention until the latter period, when William Woodworth of New York patented the celebrated Woodworth planing machine. In 1829 Uri Emmons was the recipient of two patents, one for cylindrical and one for circular planing machines. From this time to 1840 American inventive genius was actively engaged in this direction, and many patents were annually granted. In 1836 Thomas E. Daniels of Worcester, Mass., greatly improved the Bramah or circular machine, which brought it into general notice under the name of the Daniels planer. It is usually constructed with but two cutters, and the plane of the Bramah machine is entirely dispensed with. Though not as rapid in its operation as the Woodworth, the Daniels planer, with its recent modifications and improvements, is still preferred and generally used for cabinet and other fine work to which it is adapted. During the monopoly of the Woodworth machine by the patentee and his assigns, many attempts were made to supersede it by the use of stationary cutters which were modifications of the first invention of Bentham. These machines were built in considerable numbers, and were made to operate with tolerable effect. When in perfect order, they work well, and are much more rapid in their operation than the cylinder machines, but for ordinary practical purposes the latter are preferred. The Woodworth machine performs its operation by the use of cylindrical cutters, or cutters attached to a horizontal shaft revolving with great velocity while the board is borne along under and in contact with them, by means of two or more horizontal rollers which clamp the board on either side, the rollers being driven by mechanism communicating motion from the cylinder. Though the cylindrical machine was not originally invented by Mr. Woodworth, his claims covered such essential improvements in some of its details as to render the patented modifications invaluable, and thus gave him an almost exclusive monopoly of its use. This monopoly, though jeoparded by constant and fierce litigation, was triumphantly sustained by the courts during a term of 28 years, under his original patent of 14 years and two successive renewals of 7 years each. Numerous improvements are annually added to these machines for their more perfect adaptation to special uses, descriptions of which may be found in the patent office reports.

PLANT, an organized structure containing within itself the essentials to insure its nutrition and reproduction. A plant fully developed may be considered as consisting of a root, stem, and leaves, with their modifications, which are the organs of vegetation; and of flowers with stamens, ovary, ovule, and seeds, which are the reproductive organs. Every variety and intermediate form of these several parts may occur, so that in the lowest condition of plants both the vegetative and the reproductive may be contained in a single organ called the frond, as is the case in the algæ. Structurally considered, the leaf or the frond is the simplest visible condition; but the microscope reveals that even the frond and the leaf are made up of innumerable simpler bodies called cells, helping to nourish each other by a common fluid by which they are surrounded, and each having a growth of its own. This social system of cells, which, variously modified, compose every part of all plants, including alike the hardest woods and the softest tissues, may be traced through gradations becoming less coherent, until the frond breaks up into frustules as in the *diatomaceæ*, and consisting at last only of simple and minute globules, each having a perfectly independent existence. Of these last may be cited the snow plant (*protococcus nivalis*) of arctic and alpine regions, or the *hæmatococcus* and *glœocapsa* found upon moist rocks. Such plants as consist of a single cell have numerous species occurring in all parts of the world, and are termed unicellular.

PLANT CUTTER, a conirostral bird, the type of the sub-family *phytotominæ*, by some placed with the finches and by others with the chatterers. In the single genus *phytotoma* (Mol.) the bill is short, strong, conical, broad at the base, with arched culmen and lateral margins finely serrated; wings moderate, the quills from the 3d to the 5th equal and longest; tail moderate and even; tarsi strong, shorter than the middle toe, and covered with transverse scales; toes long and slender, hind one long, and all armed with curved claws; the intestine is short, an exception to the rule in vegetable feeders. Only a few species are described, in temperate South America, in woody and dry regions, often visiting cultivated fields; they live in pairs or in small flocks, and do considerable mischief in orchards and gardens by cutting off buds, fruits, and plants with their serrated bills, destroying, as if in mere wantonness, much more than is required for food; they also eat insects. The flight is short and low, and the notes very disagreeable, resembling the grating of the teeth of saws rubbed over each other. The best known species is the *P. rara* (Mol.) of Chili, so called from its note; it is about the size of a thrush, brown above, each feather edged with lighter; top of head rufous brown, which color prevails in the lower parts; tail rufous, with a terminal dark brown bar; wings dark brown, the primaries with a white bar, and the wing coverts edged with the same. It is shot by the inhabitants for its destructiveness. The nest is made in high trees.

PLANTAGENET, the surname of the royal family of England from Henry II. to Richard III. inclusive. It belonged originally to the house of Anjou, and by most antiquaries is derived from the story that Fulk, the first earl of that family, having committed some crime, in remorse went on a pilgrimage to Rome, where he was scourged with broom twigs (*planta genista*), and from that circumstance assumed the name. It is now borne through collateral descent by the duke of Buckingham and Chandos.

PLANTAIN (*plantago*, Linn.), a genus of herbaceous plants, usually stemless, belonging to the natural order *plantaginaceæ* or ribworts, which are monopetalous exogens, the stamens alternating with the petals, having a single style and straight inflorescence. The ribworts have flat, ribbed or taper, fleshy leaves; flowers borne in spikes, rarely solitary, usually perfect; calyx 4-parted, persistent; corolla membranous, monopetalous, hypogynous, persistent, with a 4-parted limb; stamens 4, alternating with the segments of the corolla and affixed to it; ovary composed of a single carpel, sessile without a disk, of 2 or 4 cells, which are caused by the angles of the placenta; ovules peltate or erect, solitary, twin or indefinite; style simple, capillary; stigma hispid, simple, rarely half bifid; capsule membranous, dehiscing transversely; seeds sessile. The affinities of the ribworts with other orders are very obscure and are the subject of much study. The species are widely distributed over the world, chiefly however in cool and temperate latitudes.—The common plantain (*plantago major*, Linn.), introduced from Europe, has accompanied civilized man, springing up near his habitations and around his settlements to such an extent that it has acquired among the American aborigines the name of "white man's foot." Its root is perennial, and its leaves are broad and 3 to 8 inches long; there are 5 to 7 nerves traversing each leaf from end to end, which when broken across are found to enclose an elastic thread; their surface is generally smooth, sometimes pilose; the footstalk is furrowed; the scape 12 to 16 inches long, including the flower spike, which is surrounded by a great many small, bracted, and greenish white corolled blossoms, persistent after withering; stamens 2, as long as the corolla. The green and ripe seeds are eaten by birds, and canaries are often supplied with the spikes as a variation of their usual food. The broad leaves are reputed good in allaying the pain from the bites of mosquitoes, and are in popular use for dressing blisters and other sores. The heart-leaved plantain (*P. cordata*, De Lam.) is very glabrous, with round-ovate or cordate, long-petioled leaves, the midrib branching into veins, the spike loosely flowered, bracts round-ovate, fleshy, pod with 2 to 4 seeds. It grows along rivulets from New York to Wisconsin and southward, blossoming from April to June. The seaside plantain (*P. maritima*, Linn.) has very fleshy, terete, entire leaves, or rarely few-toothed, smooth; cylindrical oblong spikes, ovate convex bracts, and oval scarious sepals; this species is remarkable for its thick succulent foliage, and for growing upon salt marshes. A slenderer variety is also known. The rib grass (*P. lanceolata*, Linn.) is mostly hairy, its leaves lanceolate acute at both ends, the scape deeply sulcate, long and slender. It is also called English plantain. It sometimes makes its appearance in abundance in mowing fields and uplands, and, though looked upon as a weed, yet is not distasteful to cattle. The pigmy plantain (*P. pusilla*, Nuttall) is from 1 to 4 inches high, minutely pubescent; leaves entire, flowers crowded or scattered, pod short ovate, 4-seeded, a little exceeding the calyx and bract. It grows on dry hills, from New York to Illinois and southward, and blossoms from April till August.—The herbage of the ribworts is slightly bitter and astringent, and they have even been reckoned febrifuges. Their seeds are covered with mucus; those of a French species (*P. arenaria*, Pers.) are largely exported to the north of Europe, and are probably used for sizing cotton cloths. The seeds of an East Indian species (*P. Ispaghula*, Roxburgh) are of a cooling nature and used medicinally; those of the fleawort (*P. psyllium*, Willd.) form with boiling water a rich mucilage, and are used for catarrh and nephritic affections; the *P. coronopus* (Willd.) is said to be a diuretic; and in Egypt soda is obtained from the ashes of *P. squarrosa.* Persoon enumerates 66 species of the plantain, and there are probably several more.—The name of plantain is also applied to a species of tropical fruit (*musa sapientium*, Linn.), a mere variety of the banana.

PLANTAIN EATER, the name of the *musophaginæ*, a sub-family of conirostral birds, inhabiting Africa, and living chiefly upon the fruit of the plantain. In all the genera the bill is strong, broad at the base, curved, with notched tip; wings short; tail long and broad; tarsi and toes strong, the outer one capable of being directed backward; this last, however, is denied by Swainson.—In the genus *musophaga* (Isert) the bill is large, with the culmen much advanced on the forehead; 4th and 5th quills the longest, and the tertials long and broad; tail rounded; orbital region naked. The violet plantain eater (*M. violacea*, Is.) is 20 inches long, of a beautiful shining purplish black; crown and quills crimson, on the last with a lilac tinge; bill bright yellow, passing into crimson at the tip, light and semi-transparent; a white stripe beneath the eye. It is found on the Gold coast.—In the genus *turacus* (Cuv.), or *corythaix* (Ill.), the bill is short and high, with the lateral margins finely serrated; wings short, the 4th to the 7th quills the longest; outer toe versatile; orbital region naked, and head with movable crest. The Senegal plantain eater (*T. purpureus*, Less.) is about 16 inches long, of a glossy purple color, with the head, neck, breast, and crest green; orbits naked and red; white stripe over the eye, and a black one beneath; it is very shy, and difficult to shoot from its frequenting the highest branches of the tallest trees; it is restricted to the W. coast of tropical Africa. The Cape plantain eater (*T. Persa*, Vieill.), of S. Africa, differs principally in the white margin of its crest; the *T. Buffoni* (Swains.) has the green crest tipped with red, and both a white and a black line under the eyes. The crimson-crested plantain eater (*T. erythrolophus*, Vieill.) has the body green, the face, ears, and chin white, the crest red, and the quills lilac; it is found in W. Africa. Several other species are described in Africa, all shy and handsome birds. —In the genus *schizorhis* (Wagler) the bill is short and much arched; the wings moderate and pointed, with the 4th to the 6th quills the longest; tail long and nearly even; tarsi short and robust. The crested plantain eater (*S. variegata*, Vieill.) is about 20 inches long; the color above is cinereous with brown spots, beneath white with brown stripes; head, throat, and breast brown; quills and tail blackish, the former with the inner half white, and the latter without spots; crest of the color of the head, extending on to the nape like a ruff, of narrow and sharp-pointed feathers; bill yellow. There are a few other species, of dull gray and brownish colors. All these birds are monogamous; they build their nests in trees, and both sexes assist in incubation.—The American sub-family *opisthocomidæ* is placed in the same family by Gray; the characters are essentially the same, except in the incapability of turning the outer toe backward. It embraces the single genus *opisthocomus* (Hoffm.), and the single species *O. cristatus* (Lath.) or the hoactzin; this is about 18 inches long, greenish above, with longitudinal white stripes on the back of the neck and shoulders; the forehead and long crest chestnut, as well as the primaries and abdomen; breast lighter, with an orange tint; secondaries and tertiaries edged with white; tail long, green tipped with light buff; bare space round eyes blue, legs red, and bill yellow. It lives in small flocks on the banks of the rivers of Brazil and Guiana, feeding chiefly on the leaves of the *arum arborescens* (Linn.), which give to the flesh a musky odor rendering it unpalatable. This singular bird was placed by Linnæus and by many later authors among the gallinaceous birds, which it resembles even in its gait; it is now ranked among the perchers.

PLANTIGRADES, a division of carnivorous mammals, so named because the whole foot, including the tarsus and metatarsus, is applied to the ground in walking. The toes are longer than in the digitigrade division, the form heavier, and the diet more vegetable; they have a greater facility for raising themselves on their hind feet, for clasping, climbing, and digging; the small extent of the lumbar region renders them less supple and agile; they are generally slow in their movements, and nocturnal in habit. The distinctions between these divisions are not entirely definite, and some animals are intermediate between the two, and therefore semi-plantigrade; these divisions may be represented respectively by the bears, the dogs and cats, and the civets and weasels. Beside the bears, the plantigrades embrace the glutton or wolverene, badger, raccoon, coati, kinkajou or potto, and the panda or wah.

PLANTING. See ARBORICULTURE.

PLAQUEMINE, a S. E. parish of La., at the extremity of the state, bordering on the gulf of Mexico, and including the delta of the Mississippi, by which it is intersected; area, about 1,000 sq. m.; pop. in 1860, 8,493, of whom 5,384 were slaves. It has a low and level surface, having in no place a greater elevation than 10 feet above the gulf, and a large portion is occupied by marshes. The productions in 1850 were 16,835 hhds. of sugar, 140,090 bushels of Indian corn, 589,130 galls. of molasses, 1,536,740 lbs. of rice, and 60 bales of cotton. There were 2 churches, and 280 pupils attending public schools. Capital, Plaquemine.

PLASSEY, BATTLE OF. See CLIVE.

PLASTER OF PARIS. See GYPSUM.

PLASTERING, the coating of walls and ceilings with a layer of cement, fine mortar, or plaster of Paris. The practice is of ancient date, and the plastering of the Romans is said to have been much better done than that in our own buildings. Specimens are still to be seen of ancient Roman plastering that is firm and solid, free from cracks, and smoothed and polished on the surface as if made of marble. The roofs of the houses in Venice are said to be covered with a durable plaster that withstands the action of the weather and of the sun, and is not injured by persons walking upon it. The outside of buildings is often covered with a coating of mortar, which is lined to imitate stone work, or is finished in what is called rough cast. The latter is done by throwing or splashing upon the mortar while it is yet soft a mixture of freshly slaked lime, water, and clean fine gravel, which is immediately brushed over and colored to give to the whole a uniform hue. Small stones, pebbles, and bits of earthenware and other materials are sometimes dashed on instead of using the sifted gravel. For inside work the plaster is in lime mortar, with an exterior finish of very fine and thin mortar "floated" over the surface of the rougher first coat, or of plaster of Paris, which gives a smoother, harder, and much handsomer finish. A mixture of plaster of Paris, white sand, and lime, is known as hard finish. The cornices and other ornamental designs upon ceilings or walls are usually moulded in plaster of Paris without sand, and imbedded in pieces one after another in the groundwork before this is dry. Other materials used for these ornaments are "Carver's compo," a mixture of whiting, resin, and glue; *papier maché* glued over with whiting and glue; *carton pierre*, gutta percha, and also marble dust; but all these are inferior to plaster of Paris. Plastering is applied directly upon walls of brick and mortar, the joints of which are left rough that it may the better adhere; or upon a surface of laths, which are flat narrow strips of wood securely nailed to the joists, rafters, or studs, parallel to each other, and so close together that but little space (usually less than ½ of an inch) is left for the mortar to get between them. That which passes through spreads and hardens in lumps, which key the rest of the coating to the laths. The first coat, termed the laying or scratch coat, is allowed to become partially dry, and is then roughened in lines with a sort of rake made of bits of laths nailed together, and may also be sprinkled with water to cause the second coat to adhere closely to it. The application of this, called setting, is a work of some nicety in order to obtain a layer of uniform thickness. The plasterer provides for this by marking off the surface with little ridges of mortar called screeds, which serve as gauges, and between these the fine and thin preparation is applied, filling them up evenly, and it is then smoothed over or floated by flat wooden tools called floats, or still better with flat pieces of cork. The surface is then ready for whitening and coloring, or a third coat of fine stuff or plaster made with very fine white lime may be first applied and floated, till it forms a perfectly smooth and hard surface; but this is rarely found necessary.

PLATA, LA. See ARGENTINE CONFEDERATION.

PLATA, RIO DE LA, or the river Plate, a large river, or rather a great estuary, draining with its numerous affluents a large part of South America, formed by the confluence of the rivers Parana and Uruguay, the former rising in the table land and the latter in the mountains of Brazil; total length of the estuary with its largest affluent, about 2,500 m.; length of the estuary alone, 185 m., the breadth gradually increasing from 23 m. at Buenos Ayres to 150 m. at its entrance into the Atlantic ocean between Punta Negra (lat. 34° 55' S., long. 55° 5' W.) and Cape San Antonio (lat. 36° 21' S., long. 56° 42' W.). The basin of the Plata is one of the three geographical divisions of the southern hemisphere, and is estimated to occupy 1,250,000 sq. m. In this great water system the river most distinguished for its length, directness, and volume is the Paraguay, which on receiving the waters of the Parana near Corrientes assumes the name of that stream. The Parana thus takes the most important part in forming the estuary of La Plata. The Uruguay, its other great branch, receives several important affluents, of which the Negro, the principal river of the Banda Oriental (formerly Uruguay), is the most considerable. The estuary of La Plata contains many sand banks; the N. coast is high and rocky, but the S. shores are low, and the country beyond is filled with immense plains. The currents of the Plata are impetuous and variable, owing to the immense body of its affluents, and the river is frequently visited by violent storms, chiefly raised by gales from the plains, which drive the water in a great volume in one direction, creating so many difficulties for navigation that the name of "sailors' hell" (*el infierno de los marineros*) has been conferred upon the estuary. The depth of the river increases toward its mouth, averaging there 10 fathoms; at Montevideo, however, it hardly exceeds 3 fathoms, and gradually lessens, so that vessels drawing more than about 16 feet of water cannot ascend above Buenos Ayres.—The mouth of the river was discovered by Juan Diaz de Solis in the early part of the 16th century, and has given its Spanish name La Plata (silver or argent) to the Argentine Confederation. After the flight of Rosas and the election of Urquiza as provisional director of that confederation of states, one of the first measures of his administration was a decree, issued Aug. 28, 1852, opening the waters of the Plata to all nations, to take effect Oct. 1, 1852. Soon afterward an expedition was fitted out by the government of the United States under Commander Thomas J. Page of the U. S. navy, who explored the tributaries of the Plata from 1853 to 1856, and published a narrative of the expedition ("La Plata: the Argentine Confederation and Paraguay," New York, 1859). Martin de Moussy, a French geographer, explored the Plata from 1842 to 1859, and published a *Description géographique et statistique de la confédération Argentine* (3 vols. 8vo., Paris, 1860).

PLATÆA, an ancient city of Bœotia, on the frontiers of Attica, at the foot of Mt. Cithæron, about 5 m. S. W. from Thebes. Although, according to the Thebans, Platæa was founded by them, it was always distinguished for its persistent opposition to their supremacy. In 519 B. C. it allied itself with Athens, and to that city it ever afterward remained faithful. A thousand of its citizens shared in the battle of Marathon (490). In 480 the city was burned by the Persians, and in 479 on its territory was fought the memorable battle of Platæa. (See GREECE.) For the victory gained on their soil, the confederate Greeks granted the Platæans 80 talents, and charged them with the duty of paying annual honors to the tombs of the fallen warriors, and of celebrating every 5 years the festival of the Eleutheria; and in return the independence and inviolability of their territory were guaranteed. In 431, the first year of the Peloponnesian war, the Thebans made an unsuccessful attempt to seize the city, and it attracted attention from the length of time it withstood a siege by the Lacedæmonians. The city, defended by 480 men, held out from 429 to the summer of 427, when want of provisions compelled a surrender, after which it was razed to the ground. Platæa was rebuilt after the peace of Antalcidas, but was again destroyed by the Thebans in 374. It was subsequently rebuilt by the Macedonians, and is spoken of in the 6th century A. D. by Hierocles as one of the cities of Bœotia. Its ruins are still to be traced.

PLATE (Sp. *plata*, silver), the name by which utensils of silver or gold for domestic purposes are designated. Articles of this character have from the remotest times and among all civilized nations been highly prized, and from their durability, intrinsic value, and the beautiful forms into which they are often wrought, have been esteemed the most precious heirlooms, and been held among the choicest family treasures through successive generations. The richest treasures of the temple of Solomon were of gold and silver plate, and such constituted the untold wealth taken by the Spanish conquerors of Peru from the ancient incas. (See GOLD, vol. viii. pp. 340, 341.) Though modern art has scarcely carried the manufacture of plate to higher perfection than that attained by skilful workmen of past centuries, it has succeeded in producing substitutes for it in what is called plated manufacture, equally useful and almost as beautiful as the genuine plate, at prices that place within reach of those of moderate means what constituted the luxuries of the rich. The consequence of this is, that the production of plate made of standard gold and silver has not kept pace with the increasing wealth and population, while at the same time the consumption of these metals in articles designed for the same purposes very far exceeds all former demands of the kind.—In the use of articles of plate, especially those of elaborate finish, it is often found extremely difficult to protect them from tarnishing, and indeed to free them from the dust that collects in the interstices of the chased work. The following treatment is recommended in the "Chemical Gazette," 184[illegible], p. 362. The articles are boiled in water containing to each quart about an ounce of finely ground bone ash, and after being dried are rubbed with dry woollen rags that have been saturated with bone ash by introducing them into the boiling mixture. The polishing is finished with wash leather. The powders employed for cleansing silver commonly contain mercury, and if freely used may in time render the metal brittle.

PLATED MANUFACTURE. For the sake of producing cheap articles, having the appearance of genuine plate, and the advantages possessed by this over the same utensils of copper or brass in a sanitary view, it has long been the practice to cover the baser metals or alloys with a thin coating of silver or gold, and in some instances of platinum. Covering them with silver is known as plating, and with gold as gilding. The latter process has been described under its own name, and the method of plating by the galvanic process, termed electro-plating, under ELECTRO-METALLURGY. Several other modes of plating are in use, and it is stated that one of them was practised by the ancient Romans. This consists in soldering thin sheets of silver upon vessels of copper or brass by means of some fusible alloy—a method which the French term *le doublé*, or lining, and carefully distinguished from the true plating, which they term *placage* and *plaqué*. By one the silver is applied to the articles heated to dull redness after they have received their shape, and by the other to the surface of the ingots of copper or brass before these are drawn down into sheets. In England the former process is known as French plating, it having been practised in France long after the invention and introduction in England of the new method. As early as 1742 this was established at Sheffield by Thomas Bolsover, who produced by means of it plated buttons and snuff boxes; and soon afterward Joseph Hancock applied it to a number of other articles, as candlesticks, tankards, teapots, &c. The art was soon introduced into Birmingham, where, as at Sheffield, it long continued to form a very extensive branch of manufacture, but which is now chiefly dependent upon the electro-plating process. The English method was introduced into France about the year 1808, and rapidly took the place of the other mode of plating. In 1839 it gave employment to about 2,000 workmen, and the value of the products was about 8,000,000 *francs*. The metal to be plated may be either very pure copper or a brass containing a very large proportion of copper. The nickel alloys of copper, though preferred for electro-plating, do not answer for the older process, it being found exceedingly difficult to protect the surface from oxidation, which prevents adherence of the silver. In this respect the red copper is altogether preferable to any other material, and its want of stiffness is made up by the greater thickness of the metal. Hence plated articles may be generally known by their weight. The copper is run into ingots in cast iron moulds, which are very carefully made and furnished with rising mouthpieces for the sprues. Into these the impurities float up, and the pressure caused by the head of metal adds to the solidity of the ingots. The size of these may be 18 or 20 inches long, 3 broad, and 1¼ thick. Their surface is very carefully smoothed by filing, so as not to leave any little cavity discoverable by a microscope, and a sheet of silver is then laid over the surfaces to be plated, equal to $\frac{1}{10}$ to $\frac{1}{12}$ of the weight of copper for each side to be thus covered. It is cut not quite so large as the copper, and when smoothed down upon this, and made perfectly clean, the two are bound together with wire, and a little borax is introduced around the edges of the silver, that by its melting and closing the opening the air may be excluded and the clean copper surface be protected from oxidation. The ingot is now placed upon the burning coke in the plating furnace, and the operator watches through a little hole in the door for the shrinkage of the silver as it draws down to unite with the copper. He then takes it out as quickly as possible, for the two metals are then just ready to run together and form an alloy. By cooling, the process is checked just as the alloy is formed at the surfaces in contact, causing at these surfaces a complete union. Being now cleaned, the ingot is rolled out into a sheet of the required thickness, and between each rolling it is annealed to preserve its toughness; and finally it is cleansed in hot dilute sulphuric acid and scoured with sand. The sheet is now ready for the processes by which it is converted into the articles for which it is destined; either to be stamped in dies, which is the method now most commonly in use, or to be raised by the hammer, or to be spun in the lathe—a process described in the account of the manufacture of platinum crucibles, near the close of the article PLATINUM. These processes, common to the treatment of malleable metals in general, will be described under the head of RAISED WORK IN METAL. The method of making plated wire and small strips of various shapes, half round, flat, fluted, &c., such as have been largely employed for bread baskets, toast racks, and other light open-work utensils, is as follows: Rods of copper 1½ inches in diameter and 18 or 20 inches long are used for a foundation. The silver in very thin sheets intended to cover them is cut out and turned up to form a tube of the same diameter, the edges being made to unite by lapping and burnishing them upon a smaller rod of copper, which is heated red-hot and supported at one end. The large copper rod is now introduced, and is long enough to project a little beyond the silver at each end. At the termination of the silver a groove is sunk around the rod, and into this the silver is worked so as to make the junction air-tight. The whole is next heated red-hot, and in this condition the metals are made to unite by rubbing the surface briskly with a steel burnisher. The rod may now be drawn through plates into wire and the other ornamental shapes. The electrotype process has, however, nearly superseded all these methods of plating.

PLATINUM (Sp. *platina*, originally a diminutive for silver), a grayish white metal resembling silver in appearance, and distinguished as the heaviest and most infusible of metals. Its chemical equivalent is 98.7; its specific gravity in native grains 16.33 to 19.4, and when purified and hammered 21.53. Pure platinum is softer than silver, but a very small portion of iridium imparts to it a considerable increase of hardness; it also renders the metal elastic and diminishes its strength. Its tenacity is little inferior to that of iron. It is remarkably ductile, so that it can be drawn out into very fine wires. Wollaston obtained one not exceeding $\frac{1}{3000}$ of an inch in diameter. It is worked under the hammer with somewhat greater difficulty than cast steel, and when pure may be welded upon itself or upon iron or steel at a white heat. It is melted by the oxyhydrogen blowpipe, as described in the article BLOWPIPE. In its chemical properties platinum is remarkable for resisting the action of the most powerful acids as well as of high temperatures. It is dissolved by nitric acid only when it is alloyed with a considerable proportion of silver. Its true solvent is *aqua regia*. The caustic alkalies attack it, as also nitre and bisulphate of potash. At a high heat it may be made to combine with sulphur, phosphorus, and arsenic. It forms alloys with nearly all the other metals. Its fusibility is increased by the presence of silica and carbon, especially when these are together, and the silica enters into combination with the metal. Crucibles made of platinum are injured and become rough and brittle by frequent heating in contact with charcoal. When platinum in solution is precipitated by an easily combustible organic substance, as by boiling with carbonate of soda and sugar, it is obtained in a finely divided state called platinum black, which may be collected on a filter and dried between tissue paper. The same substance may also be produced by decomposing sulphate of platinum by alcohol with the assistance of heat. In this form platinum possesses in a remarkable degree the property of condensing gases in large quantities. When placed in oxygen the metal soon absorbs several hundred times its bulk of this gas; and when afterward exposed to mixtures containing hydrogen it has the property of eliminating this and determining its union with the oxygen. Spongy platinum, a form of the metal obtained by heating the double chloride of ammonium and platinum, possesses the same property in less degree; and in the article ACETIC ACID, vol. i. p. 66, the process is described of producing this acid by abstracting a portion of hydrogen from alcohol by means of this agent. When a jet of hydrogen is directed upon a bit of the sponge, intense heat is produced by the rapid combination of the two gases; so that an apparatus on this principle, known as Döbereiner's lamp, is in use for suddenly producing a light. (See LAMP.)—In modern times platinum was first brought into public notice in 1735 by Ulloa, a Spanish traveller in America; but there are reasons for supposing that it was known to the Romans and worked by them, and was also employed by some of the alchemists. About the middle of the last century it was carried from South America to Europe, and several French silversmiths were among the first to apply it to useful purposes; and some time after this Wollaston devised the methods of working it which have been practised to the present time. The metal is found in a native state in grains and small lumps, and very rarely in nuggets of several pounds weight, in the sands of the gold deposits, associated with a number of other metals, which are seldom if ever found except with platinum. These are iridium, osmium, rhodium, palladium, and ruthenium. The last named is contained in the alloy of osmium and iridium found in the platinum ore, and is not found in that portion of it which is soluble in *aqua regia*. They are alloyed with the platinum, and this also frequently contains from 5 to 10 per cent. of iron; so that the proportion of the pure metal may not exceed three fourths of the whole. Berzelius found the native alloys from the Ural mountains and from Colombia, S. A., of the following composition:

Substances.	Ural mountains.		Colombia.
	Coarse grains.	Fine grains.	Fine grains.
Platinum	78.94	78.58	84.30
Rhodium	0.86	1.15	3.46
Palladium	0.28	0.30	1.06
Iridium	4.97	2.35	1.46
Osmium	1.96	0.00	1.03
Iron	11.04	12.98	5.31

It appears from these results that the platinum of the Ural differs from that of Colombia by containing a much larger proportion of iron; and it may be this which gives to it the deeper gray color it possesses. The following analyses of platinum from various localities are given by MM. Deville and Debray (*Annales de chimie*, [3] lvi. 449):

Analyses.	Pt.	Irid.	Rh.	Pallad.	Gold.	Copper.	Iron.	Ir. os.	Sand.	Os. & loss.	Lead?	Total.

Nos. 1, 2, and 3 were from Choco (Colombia), S. A.; 4, 5, and 6 from California; 7, Oregon; 8, Spain; 9 and 10, Australia; 11 and 12, Russia.

Among the few large lumps of the metal which have been found is one brought by Humboldt from South America, and deposited in the museum at Berlin. It is about the size of a pigeon's egg, and weighs 1,088 grains. In the museum at Madrid is a lump from Condoto in South America weighing 11,641 grains. A lump was found in 1827 in the Ural near the Demidoff mines of 11.57 lbs. troy; and more recently another of 22.33 lbs. troy, which is the largest piece known, and which is preserved in the Demidoff cabinet. A few obscure crystals of the metal have been noticed, the forms of which are either cubical or octahedral. As platinum commonly occurs loose in auriferous sands, it is often uncertain from what geological formation it is derived. Boussingault states that it has been met with in place in an auriferous vein of the syenitic rocks of Antioquia in South America; others have found it in very small quantities in greenstone and diorite rocks. In the Ural mountains it is found in deposits composed of the debris of serpentine rocks, and containing much chromic iron, the source of which is in the same rocks; and it is without doubt through these that the platinum is dispersed so sparingly as not to be detected, except when it is concentrated like the gold in the lower portions of the alluvial deposits. It is not, however, limited to repositories of this character, but has also been detected in very small quantities in the hematite of the department of Charente in France; and again in Hautes-Alpes in a gray copper ore, which also contains silver, antimony, lead, zinc, and other metals. It has also been found in the silver coins of Germany, derived unquestionably from the argentiferous ores which afforded the silver; and from the slags of their metallurgic treatment it was separated in 1847 by Prof. Pettenkofer of Munich to the amount of 15 ounces.—The commercial supplies of platinum are dependent upon very uncertain sources. The metal was first obtained from the gold regions of Choco and Barbacoas in the state of Cauca and near the head of the Atrato, South America; and afterward at various localities along the western slope of the Cordilleras between lat. 2° and 6° N. From this region it was carried to Europe in the middle of the last century, but was held of little importance from the ignorance of its properties and of the methods of working it. Discoveries were still later made in Brazil, and for some years the workings were very productive, but finally ceased to afford much more of the metal. The island of St. Domingo also produced small quantities. But the whole production of the American continent has probably never exceeded 900 pounds a year. This is but little more than has been obtained from Borneo in the East Indies, the annual product of which has been from 600 to 800 lbs. In the Russian gold mines platinum had been noticed as far back as 1819 by the miners, who called it white gold; and its true character was first recognized by Prof. Lubarski at St. Petersburg in 1823. It was first worked on the eastern slopes of the Ural mountains, and was afterward discovered and worked to much greater extent on the western slopes. Much the largest portions of the product were obtained from the washings of Nijni Tagilsk; and next in importance were those of Goroblagodatsk, near Kushvinsk. From 1827 to 1834 the annual yield of all the Russian washings was from 4,000 to 6,000 lbs. troy; and up to 1851 the total production was estimated at 2,081 puds (80,942 lbs. troy), of which 1,990 puds were from the washings of Nijni Tagilsk. The metal was introduced into the Russian coinage and made into pieces of 11 and 22 rubles each; but after the year 1845 its use for this purpose ceased, and the production has since greatly fallen off. In 1855 and 1856 there were no returns from the government mines, and in 1858 they amounted to only 7 lbs. 7 oz. 8 dwt., all from the washings of Goroblagodatsk. The private mines in the same years furnished respectively 42 lbs. 0 oz., 62 lbs. 11 oz. 2 dwt., and 328 lbs. 7 oz. 9 dwt. In North America platinum has been found in minute scales and grains in the gold washings of the Chaudière river, Canada East; and associated with it were small plates of iridosmine, the native alloy of iridium and osmium. It was discovered by Dr. Genth in the lead and copper ores of Lancaster co., Penn., in traces; and Prof. C. U. Shepard reports having found in Rutherford co., N. C., a lump weighing 2,541 grains. In California it accompanies the gold ores, and is detected in the gold itself that is taken to the mints for coinage. In 1854 it was found by Mr. George Simpson in the Rocky mountains, about 150 m. from Fort Laramie; and explorations were undertaken in 1860 to determine the importance of the discovery.—The methods in use for obtaining platinum free from the substances with which it is alloyed have for the most part been based on its being first dissolved in *aqua regia*; but recently the metallurgy of platinum has been materially modified. By Wollaston's method, after the crude metal has been digested until no more is dissolved, sal ammoniac is added to the decanted liquid, which causes nearly all the platinum to separate in the state of an ammonio-chloride. This being separated, metallic iron causes the precipitation of the remainder, and this portion is then redissolved in fresh acid and precipitated with sal ammoniac. By the application of heat the ammonia and chlorine are expelled, and the platinum is obtained in porous spongy masses. These are gently rubbed to powder, and with water in a wooden mortar are triturated with a wooden pestle until thoroughly washed. The heavy metallic particles which subside are separated from the lighter portions and placed in a brass cylinder slightly flaring at the lower end for the purpose of facilitating the removal of the metal. The moisture having drained off and being absorbed by bibulous paper placed in the bottom, a closely fitting piston is introduced and powerfully pressed down. The metal is thus formed into a coherent cake of specific gravity about 10, and its appearance changes from dull gray to a metallic lustre. The cake is next subjected for about 20 minutes to the powerful heat of a wind furnace; after which it is forged by hammering with a heavy hammer upon an anvil, the blows being always directed upon the ends of the cake and not upon the sides. It is worked down with more difficulty than iron. When a large quantity, as 500 oz., is operated upon at a time, this by the action of the press is obtained in a dense block about 5 inches by 4 and 2½ inches thick. It is heated in a smith's charcoal fire, where it is so placed that the jets from two tuyeres strike together upon it. When at the welding point or almost a blue heat it receives a blow from a heavy "drop" or vertical hammer somewhat like that of a pile-driving machine. It is then reheated, and in about 20 minutes is again struck, the process being repeated continually for a week or 10 days till the mass is sufficiently consolidated for forging into bars and sheets. The latter are rolled out, and the object of their preparation in large pieces is to make pans and alembics for concentrating sulphuric acid, which it is important to have in one piece. Vessels have thus been made in France weighing in a single piece over 2,000 oz.—By one of the other methods the platinum is taken in the spongy state, obtained as above described, and amalgamated with double its weight of mercury in a porphyry mortar. The amalgam is then compressed in a cylindrical cavity in a block of wood, and the excess of mercury is forced out by the application of a screw press; and after thus remaining for several hours it is exposed for a few minutes to a white heat, either directly upon the coals or in a crucible lined with charcoal. As the mercury disappears the platinum contracts and draws itself together in a very curious manner, and is at last obtained in a solid mass. This is next forged by repeated hammerings and heatings. By the Russian process the precipitated ammonio-chloride, after being well washed and dried, is heated in a cast iron pot till the ammonia and chloride are volatilized. The platinum remains behind of a gray color, and still combined with a little iridium. Three pounds of this are ground at a time with an iron mortar and pestle, no difficulty being experienced in using iron rather than wood, though Dr. Wollaston supposed the iron might prevent the particles of platinum from welding. The metal, being reduced to a fine gray powder, is wrapped in paper to keep it together and enclosed in a thick iron ring, which is then placed upon an anvil under a screw press. It is thus solidified into a cake, and after this is heated in a charcoal fire and again compressed, by which it is rendered malleable.—The method formerly practised by the French silversmiths was not adapted to remove the foreign metals and impurities from the platinum, and consequently the articles they prepared were defective in the properties for which especially the metal is valued. Their process, which was one of consolidation chiefly, was based on the facility with which platinum may be made to combine with arsenic and form a very fusible alloy. This they cast in moulds, and then expelling the arsenic by continued high heat obtained the metal in a concentrated form and malleable condition. The latest and most approved method is to obtain an alloy of platinum and lead by melting the ore with galena in a reverberatory furnace. The substances are well mixed together, and some glass and litharge are added, the latter for the purpose of decomposing the sulphurets. When fused, the mass, protected from the oxidizing action of the air, is allowed to remain for some time undisturbed that the osmides may collect in the bottom. The scoria is then removed, and the upper portion of the alloy of lead and platinum is run off and cupelled to remove the lead. The platinum is then refined in furnaces made of solid lime and heated by a large jet of oxygen and hydrogen. By prolonged fusion in this furnace all traces of silicon and osmium may be removed. This is the process of MM. Deville and Debray of Paris, who first made it known at the meeting of the academy of sciences in Paris, June 4, 1859, when they also exhibited two ingots of the metal weighing together 25 kilogrammes (about 55 lbs.), which had been fused in the same fire and cast in an ingot mould of wrought iron; also a toothed wheel of platinum cast in sand in the usual mode of casting iron. These chemists announced that by their method platinum may be melted in any quantity, and once melted it behaves precisely like gold or silver. An account of their researchés is published in the *Annales de chimie et de physique*, Aug. 1859, and a translation of the paper is in the 1st volume of the "Chemical News." Prof. Wolcott Gibbs of New York has recently completed an elaborate investigation of platinum and its associated metals, which led him to entirely new methods of separating these metals from each other in the wet way, either for practical operations or for qualitative analysis. An account of his researches and discoveries is published in vol. xii. of the Smithsonian "Contributions to Knowledge."—Platinum has been successfully worked in New York upon a considerable scale by Dr. E. A. L. Roberts, who employs the oxyhydrogen blowpipe for melting the metal. (See Blowpipe.) His object is chiefly to convert crude platinum and scraps into plates and wire for the use of dentists. To obtain the metal soft and tough and without flaws he finds thorough melting and welding at a white heat essential. The welding is a delicate process, requiring that the platinum should be perfectly clean and be heated in a muffle until the surface is too hot to be distinctly seen. If visible the metal is too cool to be welded, and hammering upon it will have the effect of shattering the piece. The metal should be handled with tongs plated with platinum, and hammered first with a clean hammer, weighing not more than a pound, upon a clean anvil; and both hammer and anvil should be as hot as possible without drawing the temper of the steel. The metal cools very quickly, and it is with difficulty kept at the high heat required. After being welded a heavier hammer may be used for forging. Dr. Roberts, having condensed the scraps or sponge by partially melting them very compactly together into a square block of 10 to 20 ounces weight, places two of these blocks in the muffle together; and as soon as they attain the high temperature required he removes one speedily to the anvil, and gives it 3 or 4 quick sharp blows in rapid succession, and returning it to the muffle treats the other in the same way, and so alternately till both are thoroughly welded. By long hammering the metal is made tough and fibrous; but if thrown into the water while hot, it becomes crystalline and brittle. The partially melted cakes before forging are crystalline and sonorous, and break easily like spelter.—The property possessed by platinum in so eminent a degree of resisting oxidation and the action of heat, of most acids, and other elements of change, renders it well adapted for various chemical utensils, for plates and bands employed by dentists for artificial teeth, and for retorts and stills of the manufacturer of sulphuric acid. It is used in the laboratory for crucibles, capsules, spatulas, wires for various purposes, and weights for delicate balances. The crucibles are ingeniously made from a flat disk by the process called spinning. The disk, being made to revolve rapidly when attached to the end of the axis of a lathe, is pressed upon by a blunt point applied successively to different parts of its surface, till it is at last turned over into the shape required. The alloys of platinum have been little used; but the French chemists in their investigations found that the metal when combined with some of its associated metals, as iridium and rhodium, is materially improved for most of its uses. With 25 per cent. of iridium an alloy is produced which is malleable and almost completely resists the action of *aqua regia*. With smaller proportions of iridium the alloy is softer, and by varying the proportions compounds are obtained of qualities especially adapted for particular purposes. Thus retorts for the manufacture of sulphuric acid are now made in Paris, which have the strength and stiffness of rolled iron. Some of the alloys are found when cast in moulds to take the impressions with great exactness. Tin as well as arsenic greatly increases the fusibility of platinum; and consequently it is not safe to use it for soldering the latter metal. For this purpose gold is commonly employed. When the oxides of easily reduced metals, as of lead for instance, are heated in platinum crucibles, these are in danger of being ruined by the formation of a fusible alloy between the platinum and the reduced metal.—Two combinations of platinum with oxygen are known: the protoxide (PtO), and the binoxide (PtO_2). These and their compounds possess no particular interest.—The subject of platinum is treated in much detail in Gmelin's "Handbook of Chemistry."

PLATO, a Greek philosopher, born in Athens (or according to some authorities in Ægina) in 429 B. C., died in 348. His father Ariston traced his descent to Codrus, and his mother Perictione reckoned Solon among her ancestors. His original name was Aristocles, derived from his grandfather; but it was changed to Plato (Gr. πλάτυς, broad), whether from the breadth of his forehead, his shoulders, or his diction, is not determined. Owing to his subsequent renown a parentage from Apollo was attributed to him, and bees settling on his infant lips were said to have betokened the honeyed sweetness of his style. Beside the ordinary training in gymnastics, grammar, and music, he was initiated by Cratylus into the doctrines of Heraclitus, and the study of Anaxagoras gave him the results of the pre-Socratic physics. The exuberant fancy which he subsequently lavished on dialectics at first overflowed in poetical compositions, epic, lyric, and dramatic. But he burned his epics on comparing them with Homer, and when, in his 20th year, he fell under the influence of Socrates, he thenceforth devoted himself to philosophy as that essence and soul of harmony of which rhythmical numbers are but the sensuous and shadowy embodiment. He was a pupil of Socrates during the last 8 or 9 years of that great reformer's life, and became thoroughly imbued with his profound ethical spirit, and master of his searching and potent dialectics. Plato alone, of all the disciples of Socrates, seems fully to have appreciated the intellectual greatness and seized the profound scientific conceptions of his master; and hence, while others, looking at single aspects of the Socratic teaching, framed one-sided systems which rather caricatured than adequately represented it, Plato developed its germs in all their fulness and fruitfulness; and his works are not more a product of his own genius than a tribute to the memory of his master. After the death of Socrates, Plato repaired to Megara, where Euclid, a former fellow disciple, had opened a school in which he sought to engraft the Socratic ethics on the stock of Eleatic idealism. To the ideas and impulses here acquired we owe very probably that group of dialogues in which Plato seeks to establish, against the Heraclitan doctrine of absolute multiplicity and the Eleatic assumption of absolute unity, the true idea of science. From Megara he visited Cyrene, Egypt, Magna Græcia, and Sicily. Of alleged journeys to Palestine, Babylon, Persia, India, &c., there is not the slightest evidence; and even of any philosophical fruits of his sojourn in Egypt his writings indicate but the faintest trace. In the Greek cities of lower Italy, however, where Pythagoreanism had its native home and still mainly flourished, he became more thoroughly conversant with the tenets of that philosophy. Hence in part probably his fondness for mathematical physics, for mythical and allegorical imagery, and possibly for political speculation, while its fundamental doctrine of unity developing itself in multiplicity furnished an admirable solution of the conflict between the Eleatic and the Heraclitan doctrines. Plato's general mode of philosophizing was in antiquity regarded as strongly Pythagorean. After about 10 years of foreign residence and travel he returned to Athens, and opened a school in his garden near the academy, where he expounded his doctrines in conversation and formal lectures to a large number of pupils (among whom were women disguised as men), attracted by his high reputation for eloquence and wisdom. He also devoted a portion of his time to composing and revising his works. His life thus flowed on in an even tenor, broken only by two visits to Syracuse, neither of them attended by very flattering results. One was made in the vain hope of realizing through the newly crowned younger Dionysius his ideal republic. Plato never married, never mingled in public affairs, and seems to have regarded the constitution and character of his native city with disfavor and almost despair. He spent a tranquil old age, his mental faculties to the last scarcely perceptibly decayed.—The writings of Plato were favorites alike with pagan and Christian antiquity, and have come down to us in a state of unusual completeness and textual purity. The genuineness of many of the pieces which bear his name has been disputed, but in case of most of them with little approach to unanimity on the part of the assailants. A few of the smaller pieces, together with the letters, are undoubtedly spurious, but the genuineness of all the more important works there is no good reason to doubt. They are all in the form of dialogues, in nearly all Socrates being the chief speaker, and the exponent of the author's sentiments. Their composition extended over a large part of his life, and they are to be regarded, probably, rather as marking different stages of his philosophical development, than as expositions of a perfectly matured and rounded system. The methods of philosophy Plato seems to have settled with great definiteness; but in regard to the subject matter to which those methods were applicable, he to the last regarded himself as an inquirer. Numerous attempts have been made to arrange his dialogues on some clear principle of classification, either logical or chronological; but none has been entirely successful. They bear no clear internal marks of the time when they were written, and they usually admit no sharp division according to their contents. We may perhaps most satisfactorily class them according to the leading epochs in the life of Plato. Thus some of the smaller dialogues on specific ethical points, may be referred to his first or more strictly Socratic period, To his residence in Megara we may refer, doubtless, the noble tetralogy of "Theætetus," the "Sophist," the "Statesman," and "Parmenides;" and finally, to the period of his establishment in the academy, those noble compositions, "Phædrus," the "Symposium," "Gorgias," "Phædon," "Philebus," the "Republic," "Timæus," and the "Laws;" though in what order it is impossible to decide, except that we may naturally regard "Phædrus" as the earliest work of this period, while the "Laws," by unanimous consent, is among the latest. Plato is one of the most fascinating writers that ever undertook to expound the enigmas of philosophy. He spreads the charms of an exhaustless fancy over the subtlest controversies of the dialectician. He is at once poet and philosopher, with no small measure of the sweet flow of diction, the richness of invention, the exuberant imagery, the never failing vivacity, and we may add the garrulity, of Homer. One of the highest charms of his writings is their thoroughly dramatic character; they are dialogues not merely in form but in spirit. They are conducted with all the freedom and animation of a real conversation between intelligent and highly gifted men. The writer winds his way into the discussion in the most natural and easy manner, the predetermined theme being often made to hang on some casual expression; his characters are delineated with equal truthfulness and vivacity, and a thousand life-like touches interspersed throughout lend to the whole an air of perfect verisimilitude. A light, buoyant humor, irony, sarcasm, banter, now broad, now delicate, picturesque illustration, and occasionally elaborate and gorgeous fable, alternate with and relieve the stern dialectical processes with which the reader has constantly to grapple. No wonder, therefore, that through about as sharp and thorny a path of dialectics as ever was trodden, and amid a style often needlessly and provokingly obscure, the student of Plato is yet drawn onward by a resistless attraction. It is necessary to even the most rapid exposition of the philosophy of Plato to keep in view his historical position. The field of science had received as yet no formal divisions, but the several schools before Socrates had, each for itself, sought to solve the problem of universal being. Socrates discarded the whole body of these speculations as aiming at what was unattainable, and worthless if attained. He threw himself entirely on questions of political and personal morality, as those which alone had an immediate interest for man, and investigated these by that searching process of question and answer in which he sought to draw forth an exact conception of the subject, and to distinguish it from all related or unrelated ideas. His powerful interrogation went to the core of every subject, and sought to enucleate its essential and distinguishing characteristic. Thus definition and generalization were the essential elements of the Socratic method, which Plato adopted to the full and developed scientifically. But he readmitted those elements of speculation which Socrates had discarded, bringing to bear upon them his new dialectical weapons, and thus made his system the embodiment and representative of all the wisdom of his time.—Plato makes no formal division of science. He evidently, however, regards it substantially under the threefold division of dialectics, physics, and ethics or politics. Dialectics, which with Aristotle became the mere instrument of science, logic, was with Plato the science of sciences, the science of absolute being. Physics and ethics are sciences only so far as they connect themselves with dialectics. Strictly speaking therefore dialectics covers the whole field of philosophy, while speaking in a looser way it appears as one single, though far the most important branch of it. Mathematics he does not regard as a science, but a help to science, lying midway between its absolute verities and the uncertainties of opinion. Dialectics, as the science *par éminence*, deals only with the absolute and invariable. Its subject matter consists of those transcendental, spiritual essences which Plato calls forms, species (εἴδη), improperly known as ideas. It is easy to say in a general way what these forms are. They are the eternal, immutable essences, removed from the sphere of sense, and cognizable only by the reason. They pervade the sensible world, being as it were the substance of which it is the shadow, giving to it whatever of partial reality it possesses. They thus answer undoubtedly to the intuitions and general truths of modern science, and they are now more generally explained as mere abstractions, universals, the product exclusively of the mind, and having no objective reality. Earlier scholars held them to be veritable, objective existences, subtle, half spiritual, and discerned directly by the eye of the soul, as sensible objects are by the eye of the body. Much as there is in Plato which gives plausibility to the more modern view, we yet incline decidedly to the realistic doctrine of former interpreters. The ideas or forms of Plato grew out of his strong conviction of the non-reality of matter. He adopted fully, in regard to the phenomenal world, the Heraclitan doctrine of the perpetual flow of all things. Thus, denying the reality of matter, which never is, but is always becoming, he would have denied equally the possibility of forming a science by generalizations from matter. It could have been but the shadow of a shadow. The same thing is shown by the relation of Plato's doctrine to the Eleatics. The Eleatics were not idealists in the modern sense of the term. Their absolute One was not a mere abstraction, a creature of the mind, but the totality of the objective universe, as discerned by the soul or the reason, itself but a subtler species of matter. It is doubtful if there was any pure idealism in antiquity. Again, the way in which we become acquainted with the "forms" proves their objective and real character. Were they mere intuitions or generalizations, we could arrive at a knowledge of them by those processes of abstraction and generalization to which the mind is abundantly competent. But such was not the case. The soul enshrined in the body could not possibly arrive at the knowledge of them. It must have acquired that knowledge in a state anterior to the present, when, disembodied, it stood face to face with these essences kindred to itself, and communed with them as the bodily sense here holds converse with the elements of matter. Thus all learning is with Plato merely reminiscence, the knowledge which the soul had in its anterior state being called up by the action of the senses upon the phenomenal world, in whose pictured semblances the soul learns to recall the features of the divine original. And that this doctrine of preëxistence and reminiscence is no mere poetic fiction, or imaginative symbol, is shown by the severity of the process which he employs in demonstrating it, and the high practical purpose to which he applies it. In order to establish the doctrine of preëxistence he employs one of the sharpest psychological processes in his entire works. He distinguishes between ideas drawn from the sense, and those conceptions which sense never could furnish, but which exist in the mind from the very commencement of our earthly being, as standards to which our sensible perceptions are all referred, and which consequently it must have brought with it from an anterior state. And in thus establishing the existence of the soul before coming into the body, he establishes its independence of the body, and by consequence its immortality. He reasons from the past to the future, and by showing that the soul is not dependent for its existence upon the body, he shows that it is not affected by the dissolution of the body. Preëxistence, the ideas or forms, and immortality are thus all woven into one indissoluble web of argument, of which the ideas are, as everywhere in his system, the central point. We hold, therefore, to the middle age realistic views of the Platonic forms or ideas, and the attempt to reduce them to the standard of the Scotch or French metaphysics of our own day is to ignore Plato's historical position, and lose sight of the peculiar problems of Grecian speculation. Of course it is impossible but that Plato, in applying to these assumed realities his sharp dialectical methods, should be sometimes inconsistent with himself, and resolve the objective essences into the subjective conceptions for which they really stand. And as these transcendental forms are the essence of all reality, and the end of all true knowledge, it follows that the soul's residence in the body is an evil, that the phenomena of sense, interposed between the mind and these absolute existences, are constantly deceiving and alluring it from its proper element. The great business of the philosopher, therefore, is to emancipate himself as far as possible, not only from the dominion of the animal appetites, but also from the illusions of sense, and to retire into that interior world of reflection in which his mind can commune with its kindred eternal essences. The "ideas," however, are not themselves all of equal excellence; but supreme above the others are the forms of the true, the beautiful, and the good, in which triad again the last takes the highest place, and becomes, perhaps, identical with the Deity, who thus, under the Platonic conception, seems to fluctuate between a personal being and the highest and noblest of the ideas. And as the ideas are the only objects of true science, and preparation to commune with them, and especially with the good, the noblest of them all, is the great end of philosophical striving, so in the last analysis science and virtue coincide, and the ideas furnish the basis not only of all science, but of piety and morality.—Physics Plato expounds in a great measure from a Pythagorean standpoint, and his cosmogony in most of its details scarcely rose, probably, even in his own view, above the level of plausible conjecture. The world is originated and not eternal. It is framed by the Creator out of a chaotic and formless mass, after the model of an immovable and perfect archetypal world. The two are brought into union through the medium of a world-soul, placed in the world according to the relation of numbers, and constituting a harmonizing link between the Deity and the archetypal world on the one hand, and blind and formless matter on the other. As the work of a good being, the world must be as perfect as the intractable and essentially evil nature of matter admits. Hence the universe is a unity, and has the most perfect of all forms and motions, the spherical and the circular. The stars are heavenly and imperishable essences, and the earth lies, round, self-poised, and immovable, in the centre of the world. The soul, according to Plato's conception of its nature, would come into the department of physics. It consisted, according to him, of two portions, the soul proper, the intellect or reason, divine and immortal, and a sensuous or appetitive principle, material and perishable; while intermediate between them, but approaching nearer to the reason, is a third element which he calls passion, and which thus mediates between the divine and the earthly, the intellectual and the sensuous, as the soul of the world mediates between Deity and matter. The immortality of the soul Plato argues at length and with great earnestness. He argues it from the general principle that contraries spring from contraries, death from life, and consequently life from death, from the soul's preëxistence, and consequent independence of the body, from its simplicity which renders it incapable of dissolution, from its superiority to the body, from its bearing within it the principle of life, &c. He believes in future retribution, exonerates God from responsibility for sin and suffering, and sets forth in elaborate myths the blessedness of the virtuous and the punishments of the vicious, blending, however, with his teaching the Pythagorean doctrine of metempsychosis.—In ethics Plato holds to the Socratic doctrine that virtue is a science and consequently matter of instruction. Virtue is essentially one, the good, but has various forms of development. He retains the fourfold division of the virtues into wisdom, courage, temperance, and justice. The three first ally themselves to the three divisions of the soul respectively, wisdom being the proper virtue of the intellect, courage of the passionate portion, and temperance of the animal or sensuous. Justice is the principle that pervades and regulates the whole. In discussing the nature of the chief good, which the ancients made the starting point of their ethical system, Plato avoids the opposite extremes of cynicism and hedonism, that on the one hand which excludes pleasure, and that on the other which makes it identical with pleasure. True virtue always carries with it its own enjoyment, and the virtuous man, another name for the philosopher, finds his highest happiness in communion with and assimilation to the good and the divine. Politics with Plato, as with the Greeks generally, are closely allied to ethics. The state is but the individual on a larger scale; the individual but a miniature state. Hence for purposes of moral analysis Plato turns from the individual to the state, as in deciphering an inscription he would turn from smaller and more obscure to larger and more legible characters. His analysis of a state is but an enlargement of his psychological analysis. Its division is threefold. The governing class represent the intellect, the essence of the soul, the laborers and handicraftsmen its sensuous and appetitive portions, and the soldiers or guards the intermediate passionate element. The virtue of the first class is wisdom, of the second temperance, and of the third courage; while in the state, as in the individual, justice is the principle that runs through, regulates, and harmonizes the whole. According to the ordinary Greek conception Plato makes the state supreme, and merges in it all the interests of individual and domestic life. Household relations and ties are to be unsparingly sacrificed on the altar of the state. A community of wives and of goods is to take the place of private property and of domestic life. The education and the employments of the citizens are all to be regulated by the state. Plato draws out at length his system of education. He would banish all dramatic poetry as involving the personating of fictitious characters, and thus virtually sanctioning falsehood, all music except the simpler and more manly kinds, all those fables which exhibit degrading pictures of the gods, and every thing that can foster timidity and the fear of death. The governing class in the state should consist of philosophers, of those who, having risen to the contemplation of the real and the true, can estimate at their worth the shadowy pursuits and pleasures of the multitude. A monarchy is to be preferred on account of the difficulty of finding many men qualified to rule. In the "Laws," however, Plato abandons the monarchical theory for that of a mixed government. His views are decidedly aristocratic, and he would devolve all the privileges of the government on the two higher classes, while the multitude are merely to be kept under wholesome restraint. Slavery Plato would tolerate, but only the enslaving of barbarians, not that of Greeks by Greeks.—A tendency to a trinity of doctrines runs through the philosophy of Plato. In psychology we have the trinity of reason, passion, and appetite; in ethics, of wisdom, courage, and temperance; in ontology, of being, becoming, and not being; in knowledge, of science, opinion, and sensation; in cosmogony, of God, the soul of the world, ideas, and matter; in the state, of magistrates, warriors, and laborers. The list might be prolonged still further. We remark finally, in general, that Plato, of all authors, is the one to whom the least justice can be done by any formal analysis. In the spirit which pervades his writings, in their untiring freshness, in their purity, love of truth and of virtue, their perpetual aspiring to the loftiest height of knowledge and of excellence, much more than in their positive doctrines, lies the secret of their charm and of their unfailing power. Plato is often styled an idealist. But this is true of the spirit rather than of the form of his doctrine; for strictly he is an intense realist, and he differs from his great pupil, Aristotle, far less in his mere philosophical method than in his lofty moral and religious aspirations, which were perpetually winging his spirit toward the beautiful and the good. His formal errors are abundant. They grow out of the materials on which he had to work, and the vastness and insolubleness of the problems with which he grappled. But even in his errors, the truth is often deeper than the error; and when this has been discredited, the language adjusts itself to the deeper truth of which it was rather an inadequate expression than a direct contradiction. The large and generous spirit of Platonism is a mould in which the noblest philosophies of earth may be cast.—Among the translations of Plato, the most distinguished is the Latin version of Marsilius Ficinus, in which the printed works of Plato were first given to the world (Florence, 1483). A German translation by Schleiermacher, never completed, is admirable, as far as it goes, for spirit and fidelity, and is accompanied by learned introductions which have been translated into English. Victor Cousin has published a translation into French. There is no good complete translation of Plato in English. Thomas Taylor, the translator of his works, understood neither Greek nor English. The much better versions of Floyer Sydenham embraced but a few pieces, and that recently published in Bohn's "Classical Library," by different hands, is not creditable to English scholarship. The editions of entire or of separate works of Plato are almost numberless. The first edition was published by Aldus (Venice, 1513), and another by H. Stephens (3 vols., 1578), reprinted in the Bipont edition with the Latin version of Marsilius Ficinus (11 vols. 8vo., 1781–'6). The text was first brought into a satisfactory condition by Bekker (Berlin, 1816–'18), reprinted by Priestley (11 vols., London, 1826), and was still further corrected by Ast (9 vols., Leipsic, 1819–'27). Perhaps the best edition is that of Stallbaum, in Jakob and Rost's *Bibliotheca Græca*, begun in 1827 and not yet completed.

PLATOFF, Matvei Ivanovitch, a Russian general, born among the Cossacks of the Don, Aug. 6, 1757, died at Elantchik, on the Don, Jan. 3, 1818. He was descended from an ancient family, and entered the army at a very early age. His first campaign was against the Turks in 1770 and 1771, and he was made hetman of the Cossacks of the Don by the emperor Alexander I. in 1801. He held the rank of lieutenant-general in the Russian army sent to assist Prussia against the French, serving in the campaigns of 1806 and 1807. Upon the conclusion of the peace of Tilsit, he was employed against the Turks in Moldavia, and was made a general of cavalry in 1809. He became celebrated chiefly through his services against the French upon their invasion of Russia in 1812. Though defeated at Grodno, and compelled to retire into the interior, he returned upon the abandonment of Moscow, and with 20 regiments of Cossacks harassed terribly the French retreat. He was active in every one of the many battles to which the French were forced, both in Russia and Germany, and especially upon their retreat from the battle of Leipsic. In 1814 he entered Paris with the allies. In 1815 he again commanded the Cossacks destined to invade France, and was raised to the dignity of count. At the peace he retired to his home on the Don.

PLATTE or Nebraska River. See Nebraska.

PLATTE, a N.W. co. of Mo., separated from Kansas by the Missouri river, which bounds it on the S. and S. W., and intersected by the Little Platte river; area, 410 sq. m.; pop. in 1860, 18,341, of whom 3,313 were slaves. It has a diversified surface and fertile soil. The productions in 1850 were 1,814,287 bushels of Indian corn, 129,067 of wheat, 127,892 of oats, 4,255 tons of hemp, 3,551 of hay, 59,760 lbs. of wool, and 250,311 of butter. There were 10 grist mills, 18 saw mills, 2 tanneries, 2 newspaper offices, 15 churches, and 1,784 pupils attending public schools. Capital, Platte City.

PLATTSBURG, a township and village, and capital of Clinton co., N. Y., on Cumberland bay, an indentation of Lake Champlain, at the mouth of the Saranac river, on both sides of which the village is built; pop. in 1860, 6,680. The river affords valuable water power, and there are several manufactories. Extensive barracks, about 1 m. from the village, formerly occupied by government troops, are now used for the annual agricultural fairs. The township contains, beside the county buildings, a town hall, custom house, academy, and 9 churches, viz.: 1 Baptist, 1 Episcopal, 1 Methodist (Wesleyan), 1 Methodist Episcopal, 1 Presbyterian, 3 Roman Catholic, and 1 Union.—On Sept. 11, 1814, the Americans gained a memorable naval victory over the English near this place. (See Champlain, Lake.)

PLAUTUS, Titus Maccius, a Roman dramatist, born at Sarsina in Umbria about 254 B. C., died in 184. The little we know of his life is derived from a passage in Aulus Gellius, quoted from Varro. He came to Rome when young, and went into the service of the actors, and having made sufficient money, left the city, and set up in business for himself. But failing, he returned to Rome, and was so reduced in circumstances that he was employed in turning a hand mill, grinding corn for a baker. While thus occupied he wrote three comedies, which were successful; and from that time he wrote constantly, and became the favorite comic dramatist both of the higher and lower classes. His plays continued to be performed after his death, certainly as late as the reign of Diocletian. The grammarian L. Ælius Stilo declared "that the Muses would use the language of Plautus, if they were to speak Latin." Cicero considers his wit as equal to that of the old Attic comedy. Aulus Gellius calls him *homo linguæ atque elegantiæ in verbis Latinæ princeps*. With his works St. Jerome used to refresh himself after spending nights in tears for his sins. There is great uncertainty as to the number of the plays of Plautus. When Varro wrote there were 130 which went under his name, although some were not considered his, being supposed either to have been written by another person of the same name, or to have been old plays rewritten and improved by the poet himself. Varro could enumerate only 21 which were without any question authentic. L. Ælius placed the number at 25. Those mentioned by Varro were the comedies most carefully preserved, and are all extant with one exception, the *Vidularia*, which being last was probably torn off in the manuscript. Molière imitated the *Amphitruo* in his *Amphitryon*, and the *Aulularia* in his *Avare;* and Shakespeare the *Menæchmi* in his "Comedy of Errors." The *Amphitruo* was also imitated by Dryden in his "Two Socias;" the *Mostellaria* by Fielding in "The Intriguing Chambermaid," and by Regnard in "The Unexpected Return;" and the *Trinummus* by Lessing in his *Schatz*. The *Captivi* is usually considered the finest work of Plautus, and has been pronounced by Lessing "the best piece which has ever come upon the stage." His plots were mostly taken from the Greek writers of the new comedy, although in his treatment of the subject he does not slavishly adhere to his models. Horace censures him for the inharmoniousness of his lines and the coarseness of his jests. It is a singular fact that the real name of this poet was not known until it was demonstrated in an essay published by Ritschl in 1842, that it was Titus Maccius, and not Marcus Accius, as it had always been printed. The text of Plautus is very corrupt, some of the scenes having been forged at a later period. A palimpsest manuscript was found in the Ambrosian library of Milan, which was as old as the 5th century, and this also contains interpolations. The *editio princeps* was published at Venice in 1472, by Georgius Merula. The best modern editions are those of Bothe (4 vols. 8vo., Berlin, 1809–'11) and Weise (2 vols. 8vo., Quedlinburg, 1837–'8). Thornton and Warner translated all the plays into English (5 vols. 8vo., 1767–'74).

PLAYFAIR, JOHN, a Scottish natural philosopher and mathematician, born in Benvie, Forfarshire, March 10, 1748, died in Edinburgh, July 19, 1819. He was the eldest son of James Playfair, minister of Benvie, and was sent at the age of 14 to the university of St. Andrew's to be educated for the Scottish church. Here he showed so remarkable a talent for mathematics and natural philosophy, that he was occasionally selected by Professor Wilkie to lecture to his classes on natural history; and at the age of 18 he offered himself as a candidate for the mathematical chair in the Marischal college of Aberdeen. Of 6 competitors two only excelled him, and the successful one, Dr. Trail, attributed his success chiefly to his greater age. Upon the death of his father in 1772 he was induced, as a means of providing for the support of his mother and the education of her younger children, to enter the ministry, and in 1773 he obtained possession of his father's living of Benvie, the duties of which and the education of his younger brothers chiefly occupied him during the next 9 years. In 1779 his first scientific paper, "An Essay on the Arithmetic of Impossible Quantities," was published in the 68th volume of the "Philosophical Transactions." In 1782 he resigned his living to become a private tutor; and in 1785, in consequence of an arrangement between Dr. Adam Ferguson and Dugald Stewart for an exchange of chairs, he became joint professor of mathematics with the former in the university of Edinburgh. In 1805 he was appointed general secretary of the Edinburgh royal society, and in the same year succeeded Dr. Robison as professor of natural philosophy, which position he held until his death. His literary productions comprise contributions to the "Transactions of the Edinburgh Royal Society" and the "Edinburgh Review," and a number of separate publications, of which a collected edition appeared in 1822 (4 vols. 8vo., Edinburgh). In 1795 appeared his "Elements of Geometry," prepared for his university classes, and of which many editions have been published. It was succeeded in 1803 by his "Illustrations of the Huttonian Theory of the Earth," his most labored work, and one distinguished alike by clearness of reasoning and the skill and eloquence with which facts are made to support and explain the system. In 1815–'16 he made an extensive geological tour in France, Switzerland, and Italy, to procure materials for an enlarged edition of the "Illustrations," which however he did not live to complete. In 1814 he published for the use of his classes "Outlines of Natural Philosophy" (2 vols. 8vo.), containing the substance of his lectures. His last important work was the elegant "Dissertation on the Progress of Mathematical and Physical Science," prepared for the "Encyclopædia Britannica," and left by him in an incomplete state. Lord Jeffrey says: "He possessed in the highest degree all the characteristics of a fine and a powerful understanding, at once penetrating and vigilant, but more distinguished perhaps for the caution and sureness of its march, than for the brilliancy or rapidity of its movements;" and he adds that he "was certainly one of the best writers of the age."

PLAYFAIR, LYON, an English chemist, born in Bengal in 1819. He was educated at St. Andrew's university in Scotland, and in 1834 studied chemistry at Glasgow under Professor Graham, the present master of the mint in England. Subsequently he became a pupil of Liebig at Giessen, where he took the degree of doctor of philosophy; and upon his return to England he published a translation of Liebig's "Reports on the Progress of Organic Chemistry." For several years subsequent to 1843 he held the position of professor of chemistry at the royal institution in Manchester, and during the same period was a member of the commission for investigating the sanitary condition of the large towns of England. He took an active part in the movements preliminary to the opening of the great exhibition of 1851, and for his efficient services during the whole exhibition was appointed by the queen a ompanion of the bath. He was subsequently ppointed inspector-general of museums and chools to the government, and in 1858 was lected to the chemical chair in the university f Edinburgh, which position he still occupies.

PLEADING. The pleadings in a cause are he alternate allegations, by plaintiff and de-endant, of those matters of fact which constitute on the one hand the ground of action, nd on the other the ground of defence. The cience of pleading in general consists of the rinciples of those rules and formulas according o which, for the sake of method and certainty, hese allegations are uniformly expressed. Spe-ial pleading is the invention of the English common law; it is particularly designed to develop the precise point in controversy, and to resent it in a shape fit for decision. Other ystems allow the parties to make their statements independently of each other and at large, nd then require the court, or sometimes the itigants themselves, to select from the undigested mass, as precisely as may be possible, the matter of dispute. But it is the distinctive feature of the English method that it compels the parties themselves so to guard and narrow their respective statements, that the particular question for decision, and nothing else, shall be developed in the first instance. The very essential effect of this pleading is to clear away the undisputed or immaterial matter which conceals the issue. The system of English pleading, as it existed before its overthrow 10 years ago, was one of great antiquity. Like the *brevia* or writs, that is, the formulas which were essential to the institution of different kinds of suits, pleading originated probably among the Normans, and was introduced by them into England at the time of the conquest. To go still further back, it may perhaps be safely asserted that the *brevia* and pleading of the English law had a remoter origin in the Roman jurisprudence; for it can hardly be doubted that the forms of procedure, which were their immediate models, were, like those of other continental nations of that age, framed on precedents furnished by the imperial or even by the ancient law of Rome. It has been well suggested, however, that the strict and subtle technicalities of the English pleading, which most resembles the earlier Roman forms, were not borrowed from them, but were rather the fruit of the school logic of the middle ages. It is to the period of the later and more liberal Roman law, if to any, that we owe the suggestion of any of our forms of pleading.—The pleadings were once oral altercations in open court in the presence of judges. This was certainly the mode of pleading in the time of Henry III., in the earlier part of the 13th century; and it is supposed to have continued until a much later period. These oral pleas were made either by the suitor himself or by his pleader, who was called *narrator* or *advocatus*. It was the office of the presiding judges to direct the allegations of the parties so as to develop an issue, that is, a specific matter, which one party affirmed and the other denied. While these pleadings were going on, an officer of the court made minutes of the declarations of the parties, and added to them memoranda of the issue and of the acts of the court and the parties during the progress of the cause. These official notes formed the record, and were completed by the addition of all the material incidents in the case until it was finally disposed of. That part of the record which preceded the issue comprised the pleadings alone, and these, it has been seen, were for a long time oral. Gradually the practice changed. At first probably the allegations, though made alternately as before, were now entered on the record in the first instance, and by the pleaders themselves. This seems to have been the mode in the reign of Edward IV., in the latter part of the 15th century. It was no doubt for the purpose of avoiding the inconveniences of this method that the modern plan was devised of putting the pleadings in separate papers, and either mutually exchanging them or filing them in the proper office of the court, when at a subsequent stage of the proceedings they were all together copied into the court records. It would be a long labor, if indeed it were possible, to follow out the historical development of English pleading. It is enough to say that it had become a most elaborate and intricate science, and was so for a century or more. The system, which had been designed to reduce to the utmost simplicity and certainty the controversies of suitors, had become so overgrown and embarrassed with refinements and technicalities as to be very often rather a hindrance than a help in the prosecution of causes. That the system still possessed great excellence could not be denied; but it was equally clear that in various respects it was mischievously technical, subtle, and absurd, and that in many ways it could be put to bad uses. These abuses of pleading grew in great part out of the undue prominence which had been permitted to its incidental and purely formal parts. Its substantial elements, consisting indeed only of those plain logical processes which are inseparable from the orderly examination of every disputed proposition, did not deserve the reproach to which the perversion of some artificial rules had exposed the whole science of pleading.—A sketch of the more usual forms of pleading will show the distinction which may be made between matters of substance and matters of form, and will properly preface a notice of the present modes of process. The single design of special pleading was, by eliminating all else, to reach the distinct point in controversy for the purpose of submitting it to a court or jury. In the outset of the case, therefore, the plaintiff set forth simply the facts which gave him, as he claimed, a good cause of action. This declaration, like every other good pleading, contained, or rather implied, a complete logical proposition. Its major premise was the general principle or rule of law, within which the minor premise, that is, the particular facts, were supposed by the plaintiff to be included, and the conclusion or legal inference was that judgment which he sought from the court or jury. But as it is one of the fundamental principles of the theory of pleading that legal propositions are never to be recited, but are presumed always to be in the mind of the court, the major premise and the conclusion are suppressed, and the declaration is reduced to the statement of the mere facts. Now comes the defendant, who in his answer or plea may, in the first place, traverse or deny the plaintiff's facts. If he does so he also proposes a trial of the point thus affirmed on the one side and denied on the other. If the plaintiff accepts the tender, and he must do so if it be well made, the parties are at issue and the pleadings are at an end. But the defendant may be willing to admit the facts, but may conceive that they are not included in the proposition of law on which the plaintiff in fact rests, and so do not afford a sufficient legal ground of action, or that they are stated in a form which violates some of the rules of pleading. In neither case has he any facts to adduce, and therefore instead of pleading he demurs; that is to say, as the derivation of the word imports, he waits to see whether in the opinion of the court he must answer. This demurrer may be general, suggesting that the declaration is insufficient in point of law, or it may be special, assigning particularly that it is and how it is inartificial and so defective in form. Again, the defendant may neither traverse nor demur, but may admit or confess, as the phrase is, the plaintiff's facts, and allege new facts in avoidance of them. In the first pair then, so to speak, of substantial pleadings, the defendant must either demur, or plead by way of traverse, or by way of confession and avoidance. In the first two cases an issue, in one instance of law, and in the other of fact, is necessarily produced. In the last, the pleadings must still go on until one of these issues is reached, the subsequent pleas being alternately by plaintiff and defendant—replication, rejoinder, surrejoinder, rebutter, and surrebutter. Further than the last the pleadings rarely extend; for as no case can involve an inexhaustible store of new and relevant facts, there must soon be an end of pleas in confession and avoidance, and an issue of fact or of law will then be easily developed. These various forms of pleas, traverses, demurrers, tender and joinder of issue, and the various forms of general and special issues, form the essential parts of pleading. But beside these there belonged to the science certain accidental parts, such as dilatory pleas and pleas in abatement, by which a party excepted to the jurisdiction of the court, to the competency of the plaintiff, or to the writ or declaration; imparlances of several kinds, profert and oyer, counterpleas, new assignments, and numerous others incident to the various phases of suits, all of them contrived to render the procedure more exact and certain, and all of them essential in greater or less degree to the system. Some of these rules, however, as well substantial as accidental, concerned mere matters of form. The violation of these rules was good ground of demurrer. For example, of the multiform rules which governed the production of the issue, of those particularly which demanded its unity, certainty, directness, and materiality, many were purely formal. Defects in these respects were taken advantage of by special demurrers. These pleas did not regard at all the merits of the case; they did not deny that the party whose pleading was objected to had a good ground of action or of defence; but simply raised the question whether the statement or denial of facts was made in that particular technical way which the rules of pleading required. Even though the cause of action was confessedly good, yet if the statement was inartificial (and in England, the question whether it were or not could be carried through all the courts, and even to the house of lords), the party must submit to loss of his suit or pay often heavy costs to the other side for the privilege of amending. The art of pleading possessed, then, two distinct systems of rules, the substantial and the formal. So far as only the former were looked at, the science was justly pronounced ingenious and excellent. In this view it deserved such praise as that of Lord Mansfield, who said that "its rules were founded in strong sense and in the soundest and closest logic;" of Sir William Jones, who declared that "the system was reducible to the strictest rules of pure dialectic;" or of Chancellor Kent, who pronounced it "a science equally curious, logical, and masterly." But there was another aspect of the matter which was not so engaging. Thus Sir Edward Coke, who, in language often quoted, spoke of good pleading as the sure oracle of the law, the very *lapis Lydius* or touchstone of its true sense, yet admitted that "in diligently considering the course of the books of years and terms, from the beginning of the reign of Edward III., he observed that more jangling and question grew upon the matter of pleading and exceptions to form than upon the matter itself." In short, the formalities and technicalities devised and insisted on, though they were for the sake of securing greater nicety, had become so numerous; so many fictions had been engrafted on the system for the same purpose; so completely, by the gradual accretion of all sorts of refinements and the want of judicious legislative interposition in removing them, had the substantial rules of pleading been overbalanced and often defeated by those which were only formal; by all these means, so many technically fair but really unfair advantages were offered to dishonest and quibbling pleaders, that at last the complaints against the whole science of special pleading became so loud, that nothing but its almost entire abolition could quest them. Partial and important reforms were effected in the reign of William IV. The statute 3 and 4 William IV., c. 27, § 36, swept away 50 or 60 forms of actions, leaving then only 6, or, including the 3 real and mixed actions, dower, *quare impedit*, and ejectment, 9. The so called new rules of Hilary term, 1834, simplified these remaining forms of action, and rearranged the pleadings connected with them, so that they recovered in good part some of their old vigor and excellence. But that which they sought to do and partially did, was more effectually accomplished by the common law procedure act of 1852. In that year the commissioners appointed to report upon the subject proposed to parliament a system of pleading which, with slight exception and variation, was then adopted, and now regulates the process of the English courts. The commissioners ranked the most prominent objections to the science of special pleading under 5 principal heads, viz.: the admission of fictions; prolixity of forms; the allowance of arrests of judgment after verdict, on the ground of defects in the pleadings once passed by and then first taken advantage of; vagueness and uncertainty in some cases; and finally, unnecessary precision and undue technicality in others. With respect to the first of these classes, the report proposed that all rules which compelled fictitious recitals and purely immaterial statements should be annulled. This suggestion reached the fictions involved in trover and ejectment; the fiction of color, that is, the pleading of feigned matter by means of which the party averring it seemed to have a good cause of action, though in truth he had only an appearance or color of cause; and all the like artificial contrivances. Prolixity was to be avoided by the adoption of short and plain forms in the place of the tedious verbiage of the old-fashioned pleadings. Arrests of judgment after verdict were matter of just complaint. They were granted, for instance, on motion of a plaintiff, when, though a verdict had been found for defendant, the former could show to the court that the plea was not a legal answer to the declaration; or when a good and a bad count had been inserted in the declaration, and damages had been given generally; for the law held in such a case, that it was impossible to discriminate between that part of the penalty which was inflicted for the matter laid in the good count and that charged in the bad. These abuses were also corrected by the act. The objection of undue precision and technicality was also well made. It particularly applied to the so called rules for the production of an issue. If their several requirements were violated by false averments of time, quantity, or quality, even though these points were immaterial; by duplicity, that is, by the allegation of several distinct matters in support of a single demand, or the setting forth of several distinct answers to a plea; if they offended by repugnancy, ambiguity, or obscurity; if they stated that argumentatively, or in the alternative, which ought to have been stated directly and positively; no matter what might be in these cases the substantive merits of the cause, it could easily be hindered and even defeated by the operation of a special demurrer. The commissioners wished to retain some of the rules which have been just now referred to, proposing to restrict them within limits which would secure their legitimate operation; but it was special demurrers which had particularly excited the popular dislike of the system of pleading, and it was found impossible to save any rules on which these objectionable pleas could establish themselves. With trifling qualifications, all the reforms proposed by the commissioners were adopted by the procedure act. No ground of special demurrer was allowed to remain. The still surviving forms of action, assumpsit, debt, covenant, trespass, case, with their venerable subtleties, were abolished. The old terms of art and technical forms of pleas were all cleared away, and the whole theory and intent of the present mode of procedure under the act are directed to the framing of simple narratives of facts by plaintiffs, and plain and fair answers to them by defendants. It is more than probable that for the sake of method and certainty some rules of form will still be found indispensable, and will be gradually developed; but these will be framed in consonance with that modern, equitable, and enlightened administration of law of which the abolition of the difficult and in great part useless art of pleading is one of the clearest and worthiest evidences.—In the older United States the science of special pleading had been received as part and parcel of the common law; but many of its more odious features either were never adopted, or were early, or have been gradually, reformed by legislative enactments. Still the system preserved enough of its faults, even with us, to excite complaint, and to provoke demands for its removal. The most remarkable reform thus made in this country was perhaps that effected in New York in 1848. In that year the separate equity jurisdiction which had hitherto existed there was suppressed. The code adopted for the regulation of legal processes expressly declared that in the future there should be no distinction between legal and equitable remedies; the common law practice and pleading were put out of the way, and gave place to the present system, which, in its general features, very closely resembles the equity procedure. One form of action only is allowed. The pleadings are few, concise, and must be framed in language easily understood. Allegations are to be liberally, not strictly, construed. Facts are to be respected rather than pleadings; and the latter may at any time in the progress of the suit be revised and accommodated to the proofs. In all respects the code seeks, by the utmost liberality, to assure easy and efficient remedies to suitors. Changes have been made in a like spirit, and in the same direction, in

Massachusetts and in other states; and to no part of the whole province of jurisprudence has reform addressed itself in this country more earnestly and more acceptably than to the reconstruction of the forms of process, and to the restoration of its essential efficiency and simplicity to the necessary science of pleading.

PLEBEIANS (Lat. *plebeius*, from *plebs*, the common people), a class of Roman citizens not included either among the patricians or the clients. Their origin is doubtful, although it has been supposed that they were inhabitants of the conquered territories, or were clients who had dissolved their connection with their patrons, or partly both. Originally the plebeians were excluded from the senate, from all offices of state, from the making of laws, and from marriage with the patricians. The constitution of Servius Tullius recognized their political existence, and divided them into tribes. Tarquinius Superbus, however, abolished all the privileges conferred on them by the preceding king; and although on his expulsion these were professedly restored, yet when all fears of his return had been laid aside their condition was exceedingly grievous. The first important step made toward their full consideration in the commonwealth was the establishment of the tribuneship in 494 B. C., a privilege which was still further increased by a law of Volero Publilius in 471 that the election of these magistrates should take place in the *comitia tributa*, in which the power of the plebeians was predominant. After the overthrow of the decemvirs, another point was gained by the *lex Valeria Horatia* in 449, which declared that the *plebiscita*, or decrees of the *comitia tributa*, should be of equal authority with the decrees of the *comitia centuriata*, and should become laws if sanctioned by the senate and confirmed by the *curiæ*. A change in the constitution was again made in 445, by the law of the tribune Caius Canuleius, which legalized the marriage of the two classes; but the demand of his colleagues that the consulship should be thrown open to plebeians was so strenuously resisted by the patricians, that a compromise was finally agreed upon, in accordance with which was established the new magistracy of military tribunes with consular power, to which members of both orders were declared eligible. Yet this was but a barren victory, so far as regarded its immediate effects, as the tribunes were usually chosen from the patricians. But the great point was finally gained in 366, by the passing of the Licinian laws, one of which abolished the office of military tribune, and declared that one of the consuls should always be a plebeian. The rogation to that effect was proposed in 376 by C. Licinius Stolo and Lucius Sextius, and the reading of it was then stopped by the 8 other tribunes, who had been gained over by the other party. Year after year these two men were elected to the tribuneship in the face of the fiercest opposition of the great patrician houses; but after 10 years of struggle their rogations became laws. Afterward the dictatorship, censorship, prætorship, and finally by the *lex Ogulnia* in 300 B. C. the priesthood were thrown open to plebeians. The *lex Valeria* was extended by the law of the plebeian dictator, Q. Publilius Philo, passed in 339, providing that the *plebiscita* should not require the confirmation of the *curiæ* in order to have the force of laws; and it was still further extended by the *lex Hortensia* in 286, declaring that they should not need the sanction of the senate. Henceforth the distinction between the two orders gradually disappeared.

PLEIADES, a celebrated group of stars situated on the shoulder of the constellation Taurus, regarded by Mädler as the central group of the system of the milky way. Alcyone, the brightest of the Pleiades, a star of the 3d magnitude, is considered to occupy the apparent position of the central point round which our universe of fixed stars is revolving.

PLEODONT. See LIZARD.

PLESIOSAURUS, an extinct gigantic enaliosaurian or marine reptile, found principally in the lias (secondary) formation of England, in company with the still larger ichthyosaurus. The head was of small size, supported on a long, flexible, snake-like neck, the body and tail short, with 4 limbs in the shape of powerful swimming paddles, like those of turtles or cetaceans; the skin was probably naked. This singular genus, named by Conybeare, to a lizard's head united the teeth of a crocodile, a neck like a serpent's body, the trunk and tail of a quadruped, the vertebræ of a fish, the ribs of a chameleon, and the fins of a whale. The apertures through which the air was respired are just in front of the orbits on the highest part of the head, and not at the end of the snout as in crocodiles; the paddles were probably invested with a sheath of integument, and from the natural curvature of the bones must have had a more elegant and tapering form and greater flexibility than in cetaceans. From the above details of structure it has been supposed that this animal paddled along, rather slowly, near the surface of the water, with its long neck raised and arched like that of a swan, ready to seize any fish or other marine animal which came within its reach; at times also concealing itself among the sea weeds in shallow places, its body immersed, and breathing carried on through the apertures on the top of the head; it was neither so active nor so formidable as the more robust ichthyosaurus. There are nearly 20 species described, of which the best known is the *P. dolichodeirus* (Conyb.), which attained a length of 10 to 12 feet; there were about 50 teeth in each jaw; the neck was as long as the body and tail together, having 33 vertebræ, 10 more than the longest neck of a bird; the ribs were united in front by several cartilages, enabling the animal to readily and fully inflate the lungs, and take in a supply of air for a prolonged immersion; the coracoid bones were very large, producing an elongation of the sternum, and indicating that the animal was aquatic, and able only with difficulty to drag itself along on land. The less strong and less numerous teeth show a less carnivorous disposition than in the ichthyosaurus; the lighter general conformation was suited rather for tranquil waters than to encounter powerful waves. Species are found also in the oolite and cretaceous strata, though less abundantly than in the lias, in which their numerous remains and coprolites show that the waters must have swarmed with them. For full details on the species, see Owen's "Report on British Fossil Reptiles," in "Reports of the British Association" for 1839.—The genus *pliosaurus* (Owen) includes the gigantic reptiles of the Oxford and Kimmeridge clays of England, intermediate between the plesiosaurus and the ichthyosaurus; the teeth and the bones of the limbs and trunk were like those of the former, the first being stouter and more trenchant; but they had the short neck, massive head, and cetacean-like form of the latter genus. It is interesting to note that pliosaurus did not appear until after both the genera which it in part resembles; no fragment of their bones, according to Pictet, has been found in the lias or oolite, and none until the time of the Oxford clays. The best known species is the *P. brachydeirus* (Owen), for an account of which see Owen's report in "Reports of the British Association" for 1841.

PLETHO. See Gemistus.

PLEURISY (*pleuritis*), inflammation of the pleura, the membrane which lines the chest, and also covers the lungs. Pleurisy has been recognized and described as a distinct disease from the earliest times, but practically, before the discoveries of Laennec, it was impossible in many cases to distinguish it from pneumonia. The disease, though rare in old age and in early infancy, is confined to no period of life. Prolonged exposure to cold, external violence, and the existence of tubercles of the lungs may be considered its most frequent causes, though in many instances we are unable to trace it to any particular source. The disease may be either acute or chronic. Acute pleurisy ordinarily commences with a chill, which is soon followed by a sharp pain limited to a single spot, and most commonly seated just below the breast on one side. This pain is often very intense, preventing the patient from taking a full breath, and increased by motion, by pressure, and by cough. It lasts a variable length of time, but gradually subsides as effusion takes place. In not a few instances pain is altogether absent. Cough comes on early, is short and commonly dry, and adds greatly to the distress of the patient. The respiration early in the disease is short and difficult; as the pain subsides the patient breathes more easily; but when effusion to any amount has taken place, any exertion rarely fails to render the breathing abnormally frequent. Before effusion takes place the patient commonly lies on the back or sound side, rarely on the affected side; after it the patient generally lies on the back or on the affected side. Fever is commonly present, the skin is hot and dry, the pulse frequent and sometimes hard, the urine scanty and high-colored. In the first stage of acute pleurisy the respiratory murmur is feeble, and the breathing, as before observed, is short and jerking; very early in the disease friction sounds, either slight and grazing or rubbing in character, may be heard; these depend on the exudation of plastic lymph. During this period the percussion sound remains almost or entirely unaffected. Sometimes the disease stops short at this point. Where effusion takes place, the most depending part of the chest on the affected side gradually becomes dull on percussion; as this dulness increases the respiratory murmur is lost on auscultation, or is replaced by a distant bronchial breathing; the friction sound is lost over the part occupied by the fluid, though it may sometimes still be heard above it. The vibratory thrill that is felt by the hand applied to the walls of the chest when a patient speaks is abolished over the seat of the effusion. When the effusion is moderate in amount, the height to which it rises posteriorly can very readily be marked out by percussion, and this will be found to vary with the varying position of the patient. It is at this time, and commonly near the inferior angle of the scapula, that a peculiar modification of the voice, ægophony (Gr. αἴξ, a goat, and φωνή, voice), can be heard by the ear or stethoscope applied to the walls of the chest while the patient is speaking. It consists of a variety of bronchophony in which the voice acquires a tremulous, cracked character, which has been compared to the bleating of a goat. When the effusion is very great it distends the pleural sac, the lung deprived of air being compressed against the spinal column. The diaphragm is now pushed downward, the intercostal spaces are bulged out, the side is larger by measurement than the opposite one, and is comparatively motionless in respiration. The heart is displaced, and when the effusion is on the left side can sometimes be felt beating to the right of the right nipple. In cases of recovery, as the fluid is absorbed the respiratory murmur and normal percussion note gradually return from above downward; for a long time, however, and sometimes permanently owing to the thickness of the false membranes formed from the plastic lymph effused, the respiratory murmur is feeble and the percussion sound dull at the lower part of the side. In some cases the side is restored to its natural form; in others it becomes retracted, the shoulder being drawn down, the ribs approximated, the spine curved, and the whole side rendered smaller and sunken.—When acute pleurisy occurs in a strong and healthy young adult, general bloodletting may be required; but in a majority of cases local bloodletting by means of cups and leeches is all that is necessary, and this has a remarkable influence over the pleuritic pain. Homœopathists avoid bloodletting by the use of aconite, aconite and bryonia, or colchicum. After bloodletting diuretics may be administered, and of these the best are the acetate and bitartrate of potassa, digitalis, and squill. Where the disease is obstinate it may be advisable to give mercury, but it should be given in small doses and stopped immediately upon the slightest signs of ptyalism being evinced. When the acute symptoms have subsided, the application of a succession of blisters to the affected side has a decided influence in promoting the absorption of the effusion; or instead of blisters, resort may be had to bromide and iodide of potash, or a course of sulphur. The diet should be low, and the patient where the effusion is extensive or increasing should abstain as much as possible from fluids. Perforation of the thorax has been recommended, and it would appear from numerous trials that, performed carefully, the operation is attended with little risk; but in acute pleurisy it should only be resorted to in those rare cases in which the amount or rapid increase of the effusion threatens the patient with immediate suffocation. In such cases care should be taken by the use of a proper instrument to prevent the admission of air into the thorax.—In chronic pleurisy the effusion remains for a long time stationary, and either gives rise to an acute febrile excitement or to one of a hectic character. It may be the result of an acute pleurisy, it may come on in patients debilitated by previous disease, or it may be complicated with the tubercular diathesis, the last being the case in the majority of instances. The effused fluid may be either serum mixed with flocculent lymph or pus. When the strength of the patient is good, a gentle mercurial course with diuretics and the use of flying blisters or ioduretted liniments will often succeed in removing the effusion. Bromide and iodide of potash are often all that is necessary. If the patient be broken down, tonics and cod liver oil with iodine may be advisable, while ioduretted liniments are freely employed. In young persons, particularly in children, if there be no tubercular complication, the operation for empyema is generally successful.—In some persons pleurisy gives rise to extensive effusion without causing any symptoms to attract the attention of the patient. Sometimes a person may be seen with one pleural cavity distended with fluid, and yet pursuing his ordinary occupations scarcely conscious that he is ill. This is latent pleurisy, the treatment of which is the same as in acute pleurisy, except that it should be less active.

PLEURO-PNEUMONIA (Gr. πλευρα, the side, and πνευμων, the lungs), an inflammation occupying the pleura and the substance of the lungs at the same time. The term pleuro-pneumonia is also applied to a peculiar epizootic disease among cattle, which is especially characterized by certain lesions of the thoracic organs. Although writers have attempted to trace the history of this affection to the most remote periods, no description sufficiently exact upon which to found any decided opinion had been offered previous to the year 1765, when Bourgelat, the founder of the royal veterinary school of France, gave an excellent account of pleuro-pneumonia as it occurred among the cattle of Champagne. Until 1792 the disease appears to have been confined chiefly to the cattle of the mountainous regions, such as the Vosges, the Jura, the Alps, Upper Silesia, and Piedmont; but soon after that date, and until the year 1820, it extended through the most of Europe. This period was marked by desolating and bloody wars, and the movements of troops, carrying with them large numbers of cattle for their support, are supposed by many writers to have been the cause of this extension. From 1820 to 1827 the disease invaded the highly cultivated regions and rich valleys of Italy, Germany, and France, where it has continued to a greater or less extent to the present time. Pleuro-pneumonia was introduced into Holland in 1833, and committed the most terrible ravages, particularly in the southern portions. According to the official reports, Holland lost, from 1837 to 1839, 28,000 head of cattle by this disease alone. It made its appearance in Belgium in 1837, and in England in 1841. During the winter of 1859 and 1860 this fatal disease became very prevalent in the London dairies, more particularly upon the S. side of the Thames. The attacks were marked with much virulence, and the fatality was reported to be as great as 95 per cent. From its introduction into England in 1841 until the present time, pleuro-pneumonia has existed not only in the United Kingdom, but also in most of the countries of northern and western Europe.—The disease first appeared in the United States, in the states of New York and New Jersey, in the year 1843, introduced, as it was supposed, by a cow imported from Germany. It however did not spread to any extent, and does not seem to have attracted much notice. In the spring of 1859 pleuro-pneumonia made its appearance in Massachusetts, and during that year destroyed many cattle. Affections of the lungs had always been observed to a limited extent either as the result of common inflammation, or of improper management as regards stabling and food; but nothing possessing the characteristics of the present epizootic had ever been noticed. The disease first made itself apparent in a cow which had recently arrived from Holland, having been imported together with two other cows and a heifer by Mr. Chenery. These animals were obtained from Purmerend, about 10 m. N. of Amsterdam, where no disease was known to exist at the time. They were sent to Rotterdam, where pleuro-pneumonia is said to exist generally to a greater or less extent, and there they remained several days before being shipped. After a passage of 47 days they arrived at Boston. On examination they were found to be in a bad condition, being much emaciated and bruised, and one of them unable to stand. They were taken to Mr. Chenery's farm, situated upon a high hill in the town of Belmont, about 6 m. N. W. from Boston. The barn in which they were placed is square, about 50 feet each way, and the part in which the cattle are kept not far from 8 feet high. The arrangement is such that the heads of the animals are directed toward a square opening in the centre, from which they are fed. There is an opening in the roof for ventilation, and a few windows in the sides of the barn. The building, being closely and substantially constructed, was undoubtedly deficient in ventilation, particularly considering the number of cattle which were housed within it, 42 at the outbreak of the disease. The first of the cows in a bad condition when landed at Boston died at the end of a week, on May 31, and the second two days after. They were not examined, it being supposed that they had died solely from the effects of the voyage and the treatment they had then received, and not from any disease of the lungs. About a month after this the third cow was found to be sick. She died after an illness of 9 days, and 75 days after leaving Rotterdam. There was no post-mortem examination. The fourth animal remained in good health. About Aug. 1 a cow imported from Holland in 1852 was taken sick and died in 20 days. From this time other fatal cases followed in rapid succession, so that in the course of two months Mr. Chenery had lost about 30 animals. Examinations were made, and it was abundantly shown that the disease was essentially an affection of the lungs and pleura. No isolation was thought necessary or attempted until Sept. 1, and then only for a short time. This was not practised again until the ensuing spring. No attempts were made to prevent the communication of the disease to cattle in the adjoining pastures, and notwithstanding this freedom of communication no instance of such transmission is known to have occurred within 20 m. of Belmont. Mr. Chenery lost no cattle from pleuro-pneumonia after Jan. 8, 1860. The day on which the first cow died (June 20), 3 calves were sold to a farmer in Brookfield, a town about 50 m. W. from Belmont. They were taken by railroad the entire distance, with the exception of the last 5 m. On the way, while being driven, one of the calves was observed to falter, and at the end of the journey was evidently sick. It was then placed in a barn where there were 40 head of cattle, and remained there 4 days. Afterward it was placed in another barn containing 20 cattle, where it died in 10 days. The other calves remained well. About two weeks after the death of the calf, one of the oxen of the herd of 40 became sick and died after two weeks' illness. Two weeks after this another ox sickened and died, and afterward at longer or shorter intervals others died, until 17 oxen and cows were lost, and, as subsequently appeared, the whole stock became greatly diseased. During the winter, 6 or 8 of the oxen of the herd of 40, where the sick calf remained 4 days, were employed in teaming and apparently well. They remained a single night with a herd which afterward became diseased. Another animal of this same herd was sold to a man in a neighboring town, and he also lost a number of his cattle. A yoke of oxen also from this herd were sold and went into another herd in the same town, where they remained only 5 days, and one third of this last herd became diseased. This same yoke, still apparently in good health, were placed in a team of 22 yoke of cattle employed in moving a building a distance of 4 or 5 m. The whole of these cattle are said to have become diseased, and subsequently 11 other herds to which they belonged took the affection. It is a singular fact that animals which had become diseased in Brookfield were driven to other towns, and, although other animals were near them and much exposed during their passage, yet the amount of subsequent disease was very small, and it did not extend beyond a space of 10 or 12 m. square around Brookfield. The appearance of this malady in Belmont and Brookfield caused the people to seek from the legislature the enactment of such laws as would arrest the progress of the disease, and cause its extirpation if possible. Certain acts were passed, and a board of medical commissioners appointed to investigate the subject. Before they had entered upon their duties, however, the progress of the disease appears to have been stayed, and they were unable to discover any case or cases of the affection which were recent or in an active stage. Their investigations therefore were confined to the surviving animals which were diseased, or which were supposed to have been exposed to the disease. The results showed "that animals that had been ill and had recovered their usual signs of health presented more or less evidence of previous disease in the lungs, now completely arrested, and that some of those which had been freely and continuously exposed presented no evidence of disease either during life or after death." In no case did the examinations reveal disease in an active state. Directly or indirectly this epizootic proved fatal to nearly 1,000 head of cattle in Massachusetts.—The most unmistakable signs of pleuro-pneumonia are derived from auscultation and percussion of the chest, but we cannot by these means alone distinguish this disease from simple inflammation of the lungs. Among the earliest external symptoms is a peculiar short, dry, painful cough, observed more especially in the morning, or when the animal rises after lying down, or is allowed to drink. There is loss of appetite and a diminution in the secretion of milk. The animal becomes sluggish and dull, and if at pasture separates itself from the rest of the herd. There is an unusual dilatation and contraction of the nostrils, accompanied with a short, quick respiration. In young, powerful animals, the mucous membrane of the nose is at the commencement of the disease red and dry; but as it advances the color changes to a yellowish white, and there flows from the nostrils a clear and thin, or a viscid and variously colored fluid. Masses of hardened excretions, sometimes as large as the finger, are often thrown off from the bronchial tubes. Chills occur from time to time, and the horns and ears are alternately cold and warm. A peculiar stiffness affects the muscular system generally, and the animal shrinks from pain if pressure is made upon the chest behind the shoulders, or upon the lumbar regions. The local signs are often present in a slight degree for many weeks, without the manifestation of any constitutional symptoms. At the commencement of the disease in strong young animals the pulse is full and hard, from 25 to 40, instead of from 22 to 25 as in health; but in those which are weak and badly nourished it is soft and full. Finally it becomes in all soft and rapid. When the febrile symptoms first set in, the animals stand with the back curved upward and with the head and neck outstretched; as the disease advances, they almost always stand with the anterior portion of the body immovable. They rarely lie down, and then only for a short time, resting either upon the affected side or upon the breast bone. Toward the close of the disease, when suffocation is imminent, they lie with the head and neck stretched out and the mouth open. The hair loses its lustre and stands up, the skin becomes dry, and the perspiration has a peculiar odor. Appetite and rumination cease entirely in the febrile stage. The act of drinking is difficult and excites cough. The eye has a wild, staring look in the well fed, but in the weak and impoverished it is sunken in the orbits. From the dry mouth there flows more or less viscid, dirty, offensive fluid, or a frothy saliva. The urine is of a dark brown color, and has a strong odor. The fecal matter at the commencement of the disorder is less abundant, firm, and is also of a dark brown color. At a later period in the disease there is either constipation, or the fæces become hard and black, or green, watery, and offensive. The duration of the disease depends upon a variety of circumstances, upon the character of the epizootic, the strength and general condition of the animal, and more especially upon the length of the non-febrile or chronic stage. If this be long, the disease may last several weeks or even months. If, on the contrary, the febrile period make its appearance early, or at the commencement of the disease, the latter may terminate in from 7 to 14 days, seldom earlier, and often later. If the affection is to prove fatal, there is great emaciation; the extremities, the ears and horns become cold, the respiration is more and more labored, and life terminates either from suffocation or extreme weakness. An imperfect recovery may sometimes take place, and the animal afterward die of an effusion into the pleura and pericardium, or of a chronic pulmonary œdema. Occasionally complete recovery takes place, but this is only possible when the disease is checked at the commencement or at an early period.—The morbid appearances in pleuro-pneumonia vary according to the period at which the animal dies or is killed. In animals killed early in the disease no exudation is found, but the interlobular cellular tissue is, in isolated portions, more filled with blood than is natural. If the disease is a little more advanced, we find this tissue thickened by a deposit into its meshes which renders it firmer. The pulmonary tissue also becomes more or less œdematous, or filled with a watery fluid, so that in some parts no air can enter, while in others it is only partially excluded. At the commencement these appearances are generally seated in the deeper portions of the lung, the pleura not being affected. If, however, superficial portions are attacked, the pleura participates, becomes opaque, and still later is covered by a whitish layer upon its surface, and by a deposit beneath it similar to that mentioned as occurring in the interlobular tissue. In very rare cases, these changes take place not only in the interlobular tissue, or in this and the pleura, but also in the very substance of the lung itself, which is the seat ordinarily of œdema only. The disease generally attacks only one lung. In a more advanced stage the lung undergoes such changes as to present when cut a marbled appearance; this appearance occurs in masses of variable size, sometimes involving one quarter or one half of a whole lung. At the same time the pleura is covered with a layer of false membrane, the thickness of which varies in different cases. A similar product is found also upon the pleura covering the ribs; also upon the diaphragm and the pericardium. An effusion of fluid takes place into the cavity between the two pleuræ, more or less compressing the lung. Still later the lungs are found much enlarged, and their weight much increased, from 4 or 5 lbs. in their normal condition to 20 or 30 lbs. They are firm, compact, liver-like, and there is an absence of crepitation. The cut surface presents the same marbled appearance as before, only in a more marked degree. This peculiarity is owing to the decided contrast in color between the layers of infiltrated interlobular tissue, which is sometimes from one to two lines thick, and the lobules themselves which they enclose. A sort of network of a somewhat irregular quadrilateral form, not unlike the veining of some kinds of marble, is thus formed. From the cut surface a red serum or watery fluid flows, which when removed leaves the lung permeable to air.

On close examination the smaller air tubes do not present a trace of exudation, and in the larger ones the mucous membrane is perfectly normal. The new substance found in the interlobular tissue varies in different parts. When it is in contact with the lobules it resembles cellular tissue in process of formation. At the same time it cannot be distinguished from that which forms in other inflammatory conditions in the neighborhood of organized parts. The portion of new material furthest removed from the living tissue is frequently not organized, and may form a cheesy layer very friable and composed of distinct laminæ. As the disease advances, in many cases irregular portions of the lung of various sizes are partially or entirely separated, and afterward become enclosed in a sac of organized tissue several lines in thickness. This change is not unlike what we find in tubercular disease, excepting that in this last the encysted masses are much smaller. These masses are not always completely detached, but are retained in connection with the surrounding portions, thus remaining for some time partially organized. Within this sac in recent cases pus is found, sometimes amounting to a pint or more; and loose, floating in the pus, is the hard mass of separated lung tissue, easily recognized by its structure. In favorable cases, the fluid contained in the sac becomes gradually absorbed, leaving behind a yellow, granular, brittle mass, sometimes 3 or 4 inches in diameter. The smaller of these in course of time undergo further change, by which they are converted into chalky concretions. As a general rule these lie as inert masses, unconnected with the neighboring lung tissue, although sometimes giving rise to a good deal of irritation, and not unfrequently thus causing death. The condition of the blood in pleuro-pneumonia has not been sufficiently examined to enable us to decide with any certainty how far it varies from the healthy standard. In the other organs usually no changes are found, and if any exist they are not essential.—As to the nature of pleuro-pneumonia, there exists a great variety of opinions. Many regard it as a local and specific disease, and as eminently contagious; while others regard it as differing in no respect from ordinary inflammation of the lungs, occurring in an epidemic form, without the properties of contagion. As regards this point, Prof. Simonds, who may be properly regarded as the highest European authority on this subject, says: "Pleuro-pneumonia signifies inflammation of the pleura and the substance of the lungs; the disease itself was not really of an inflammatory character. On the question of its contagiousness, we had but too strong evidence that it was contagious, and unhappily for the country this fact had been too much lost sight of. In fact, this disease was an epizootic. . . . Many diseases were disseminated both ways. The morbific matter entered the system, and when seated there poisonous exhalations were given off. This was the case in small pox. After the disease had reached a certain stage, pustules were formed, and each pustule contained the same morbific matter as was originally inhaled. It was not the case that every animal exposed was infected, any more than it was with man. There must be a susceptibility as well as a cause. . . . The malady itself was not an inflammatory, but a local and specific one. The morbific matter enters into the blood by respiration, and then concentrates itself in the lungs. This affection was in many respects very peculiar. It is an eminently fatal disease. . . . It always was a fatal disease, and always would be. In no one case has an animal ever been cured; the disease is sometimes arrested, but never cured. . . . When does its contagion cease? is a question upon which there has been much discussion, and which is still undecided. As soon as the animal sickens, the disease is contagious. If it was arrested, it was not easy to say how soon the animal might safely mix with others." Delafond gives the following as a portion of the results of his investigations: "The malady, while in a herd of cattle, presents all the general characters of contagious affections. The number of well authenticated examples of contagion amounts to 505. It is not certain that those who take care of affected animals can communicate the disease to those which are healthy. Twenty-six veterinary surgeons of high standing in France, Germany, Italy, Switzerland, Belgium, and Holland, have published their opinion in favor of the contagiousness of the disease. The time of incubation is from 24 to 25 days; but as it is difficult to settle precisely the moment of contagion, we must admit that the time is from 30 to 40 days—more often within, very rarely beyond this. The nature of the virus, like that of all contagious diseases, is still unknown. Its seat appears to be the affected lung. The expired air, the nasal mucus, the saliva, the emanations from the affected organs, are the ordinary vehicles. Finally, the contagious atmosphere around the animals is limited, and cannot be carried far by currents of air." The evidence upon this point of contagion is exceedingly contradictory, and yet it is one of the most important questions, so far as the prevention or extirpation of the disease is concerned. Those who oppose the view of contagion see a sufficient cause in certain combined influences. They believe that the atmospheric conditions and those circumstances, of a character but little understood, leading to the spread of epidemics generally, are also in action in this. Both contagionists and non-contagionists admit that the disease may and does arise under circumstances which preclude the probability of any contagion, that the disease in fact may arise spontaneously. "If," says Wyman, "it arises spontaneously, then the circumstances for its propagation, if contagious, are the most favorable possible, and the disease should spread with the greatest certainty and rapidity; but this certainty and rapidity have not been observed to accompany spontaneous development."—As regards the origin of the disease in Massachusetts, there is no possibility that the first animal which sickened could have been exposed to any animal ill of the disease within 75 days, unless we assume that the two cows which died from supposed ill treatment on the voyage died of pleuro-pneumonia, of which there is no evidence whatever. There is no reason to suppose that the disease existed previously among other cattle of the herd, and we are therefore compelled to admit that it remained in a state of incubation during 75 days, or that it arose spontaneously at Belmont. On the other hand, the outbreak of the disease in Brookfield upon the introduction of the calf from Belmont looks very much like the product of contagion. At the same time, there are many points which are not easy of explanation. There is no doubt that animals became sick after the introduction of the calf among them, but it may be questioned whether the outbreak did not occur in consequence of certain other conditions, existing in a limited territory. How also can be explained the fact, that if any of the diseased cattle came in contact with a herd in Brookfield, the contact was said to be followed by disease in some of the herd; but when the diseased animals were driven to other towns, and mingled with other herds, such exposure was not followed by disease? The disappearance of the disease was also peculiar, and not such as would be expected if the contagious element was as great as has been represented. Without pursuing this subject further, we may remark that we do not consider that the contagious properties of pleuro-pneumonia are by any means clearly established. In other countries this disease has gone from place to place in the form of an epidemic, and has not been controlled by measures which, as a general rule, are found to control other contagious diseases. It pursued a similar course in Massachusetts; it took its origin in Belmont, spread for a time in certain localities while the epidemic influence lasted, and then disappeared. The most stringent measures of slaughtering and isolation did not prevent its diffusion.—With regard to the treatment of pleuro-pneumonia, very little that is satisfactory can be said. By way of prevention, the diseased animals should be immediately separated from the healthy. Especially should all overcrowding be avoided, and strict attention should be paid to proper ventilation and food. Experience has amply shown that inattention to these measures tends to produce disease among the healthy, and to increase its severity where it already exists. Inoculation has been practised in various countries, by inserting the serous fluid taken from the lungs of animals affected with pleuro-pneumonia into the bodies of the healthy, but with no satisfactory results.

PLEYEL, Ignaz, a German composer, born at Ruppelsthal, near Vienna, in 1757, died in Paris, Nov. 14, 1831. A pupil of Haydn, he visited Italy, where he became acquainted with Cimarosa, Guglielmi, Paisiello, and Pugnani. In 1787 he was appointed chapelmaster in the cathedral of Strasbourg, but lost this post during the revolution. A few years later, having removed to Paris, he became a publisher of music, and afterward established a pianoforte manufactory. He wrote trios, quartets, and sonatas for the piano, which had remarkable success in their time.—His son, Joseph Étienne Camille, also a composer and pianist, born in 1788, died in 1855, succeeded him in the direction of his manufactory, and made various improvements in the construction of the instruments. The pianist Kalkbrenner was his partner.—Camille's wife (Mlle. Marie Mocke), a pupil of Kalkbrenner, was once considered one of the greatest living pianists. She still enjoys a high reputation.

PLICA POLONICA (Lat. *plica*, to knit together), a disease of the hair bulbs peculiar to Poland, and so named from the manner in which the hair is matted together. In this disease the hair bulbs are said to become swollen and acutely sensible; they secrete a viscid substance having a smell of rancid fat, by which the hair is matted together, and this, growing to an extraordinary length and swarming with vermin, becomes horridly filthy and offensive. The general opinion is, however, that the disease is merely the product of filth and neglect, and requires for its cure nothing but the free use of the scissors and the subsequent application of soap and water. The writer once saw a Polish female patient who was said to have plica, in whom the growth of hair was enormous, and this, untouched for years by a comb, formed a tangled mass traversed by myriads of vermin; but under the superincumbent filth the hair bulbs were perfectly sound and natural.

PLINY. I. The Elder (Caius Plinius Secundus), a Roman author, born A.D. 23, died in 79. The two cities of Verona and Novum Comum (the modern Como) contended for the honor of being his birthplace, and the weight of authority seems to incline in favor of the latter. He belonged to a noble and wealthy family, and when 23 years old served in Germany under L. Pomponius Secundus, whose life he afterward wrote, and was made commander of a troop of cavalry. While serving in this region he composed a treatise *De Jaculatione Equestri*, and began a history of the Germanic wars, which was finished in 21 books. Returning to Rome in 52, he studied jurisprudence, and practised as a pleader, but does not seem to have been very successful. About this time he wrote a treatise, in 3 books, on the education of an orator, entitled *Studiosus*, and during the reign of Nero composed a grammatical work in 8 books, called *Dubius Sermo*. Appointed procurator of Spain, he held that office until a little before A. D. 73, when he returned to Rome, and became an intimate friend of Vespasian. Probably at this time he continued the history of Aufidius Bassus, in 31 books, which brought the narration of events down to his own time. An account of his death is given in a letter of the younger Pliny to Tacitus (*Epist.* vi. 16). He was stationed at Misenum in command of the fleet when, on Aug. 24, A. D. 79, his attention was directed by his sister to a cloud of very unusual size and shape, which appeared sometimes white and sometimes blackish and spotted. It was afterward discovered that it proceeded from Vesuvius, and was the precursor of the great eruption which destroyed Herculaneum and Pompeii. He immediately went to an eminence near at hand to obtain a closer view of this phenomenon, which shot up to a great height. Desiring to make a fuller examination, he ordered a light vessel to be got ready, and provided himself with tablets to take down his observations. At the solicitation of the mariners of Retina, he went to their assistance, and commanded the ships to be launched to save the inhabitants of other cities upon that coast. Proceeding to the very point of danger, he dictated observations upon the phenomena and attendant terrors of the scene. So close did he come to the mountain, that there rained upon his ships a storm of pumice stone, pieces of burning rock, and hot cinders, which kept constantly falling thicker. Moreover, the sudden retreat of the sea left them in danger of falling aground. In this emergency the pilot advised him to return; but Pliny, remembering the maxim of Terence that fortune favors the brave, ordered the steersman to carry him to Pomponianus, who was at Stabiæ. The latter was about to set sail in the greatest consternation; but Pliny, in order to quiet his apprehensions, ordered a bath to be got ready for himself, and partook of his supper with apparent unconcern, assuring his friends that the flames, to which the darkness of the night gave a terrific appearance, arose from the burning of the villages which the peasants had abandoned. He then retired to rest and slept soundly; but the court of the house was filling so fast with cinders, that he was aroused and joined his friends, who were in doubt whether to remain in the house, which was now continually rocking violently from side to side, or to trust themselves to the fields. They decided upon the latter course, tying upon their heads pillows to protect themselves from the storm of stones and cinders. It was now day, but the profound darkness was relieved only by the light of the torches. Going to the shore, they found the sea too tempestuous to embark, and Pliny lay down upon a sail spread out for him. A strong smell of sulphur, the forerunner of approaching flames, obliged the friends to retire; but no sooner had Pliny's slaves raised him from his recumbent position than he fell down dead, suffocated, according to the generally received theory, by some noxious vapors, for he had naturally weak lungs; according to another theory ("Transactions of the American Academy of Arts and Sciences," new series, vol. vi.), from apoplexy following unusual exertion or excitement, or possibly from a fatal crisis in some disease of the heart previously existing. Three days afterward his body was found, bearing no marks of violence.—Pliny was one of the most industrious of writers. As an instance of the economical use of his time, his nephew relates that when once his reader did not pronounce a word correctly, some one present told him to repeat it. Pliny, asking the person whether he had understood it before, and receiving an affirmative answer, said: "Why then would you make him go back again? We have lost by this interruption about ten lines." In Rome he always rode in a chariot to save time, and once blamed his nephew for walking so much, inasmuch as he thus wasted much time which might be profitably spent in study. So great a mass of information had he collected by this course, that while he was procurator of Spain he was offered for his materials 400,000 sesterces by Largius Licinius. He bequeathed to his nephew 160 volumes of *Electorum Commentarii*, written extremely fine on both sides. The only work of his extant is the *Historia Naturalis*, in 37 books, which embraces astronomy, meteorology, geography, mineralogy, zoology, botany, and medicine, beside treating of painting and statuary. The number of authors quoted in this work amounts to between 400 and 500, and the number of volumes to about 2,000. "He was," says Cuvier, "an author without critical judgment, who, after having spent a great deal of time in making extracts, has arranged them under certain chapters, to which he has added reflections, which have no relation to science properly so called, but display alternately either the most superstitious credulity, or the declamations of a discontented philosophy, which finds fault continually with mankind, with nature, and with the gods themselves." There have been many editions of his work, the first of which was published at Venice in 1469. Among the others may be mentioned those of Hardouin (5 vols. 4to., Paris, 1685); Lemaire (10 vols. 8vo., Paris, 1827–'33); Panckoucke (20 vols., Paris, 1829–'33); and Sillig (5 vols. 12mo., Leipsic, 1831–'6). It has been translated into English, German, French, Spanish, Italian, Dutch, and Arabic. An English translation was published by Philemon Holland (London, 1601), and there is another by Dr. Bostock and H. T. Riley in Bohn's "Classical Library" (6 vols., London, 1855). II. THE YOUNGER (CAIUS PLINIUS CÆCILIUS SECUNDUS), a Roman author, nephew of the preceding, born probably in Comum in 61 or 62, died about 116. He studied rhetoric at Rome under Nicetes Sacerdos and Quintilian. He composed at the age of 14 a Greek tragedy. In his 19th year he spoke frequently in the forum, and afterward was employed to plead causes before the courts of the centumviri and the senate. After serving in Syria as a military tribune, he was made quæstor Cæsaris, prætor about A. D. 93, consul in 100, and in 103 proprætor of the province of Pontica, where he remained nearly two years. He was also curator of the channel and banks of the Tiber, and it would seem from his epistles that he also attained the rank of senator. He and his friend, the historian Tacitus, were considered the two most learned men of their time. His only extant works are the *Panegyricus*, written upon his appointment to the consulship in 100, and which has been severely criticized for its fulsome praise of Trajan; and his *Epistolæ* in 10 books. The first 9 books of the latter are addressed to various individuals, but the 10th, which is most important, is taken up with the correspondence between Pliny and Trajan. In this book occurs the celebrated letter in regard to the early Christians, in which he characterizes their religion as a "perverse and extravagant superstition," and the reply of the emperor, which shows him to have been the more enlightened man of the two. The first edition of the *Epistolæ* is that of Venice (4to., 1471), as well as the first of the *Panegyricus* and *Epistolæ* together (8vo., 1508). Among the best editions of both works may be mentioned that of J. M. Gesner, by G. H. Schäfer (Leipsic, 1805), which contains a life of Pliny by Cellarius, and that of Gierig (2 vols. 8vo., Leipsic, 1806). The edition of the *Epistolæ* by Cortius and Longolius (4to., Amsterdam, 1734) is said to be the best. A life of Pliny, more elaborate than that of Cellarius, has been written by Masson (8vo., Amsterdam, 1709). There have been two English translations of the *Epistolæ*, one by Lord Orrery, the other by Melmoth.

PLIOCENE (Gr. *πλειων*, more, and *καινος*, recent), in geology, one of the tertiary groups as arranged by Lyell, so named because the plurality of its fossil shells belong to recent species. The term post-pliocene is applied by Lyell to those more recent groups in which no extinct species of fossil shells are found, but which are below those that contain relics of man. (See GEOLOGY.)

PLOCK, a government of Russian Poland, bounded N. E. by Augustowo, S. and S. W. by the Bug and the Vistula, which separate it from Lublin and Warsaw, and N. by Prussia; area about 6,000 sq. m.; pop. 570,000. It consists of parts of the old palatinates of Masovia and Plock and of the territory of Dobrzyn. Beside the Vistula and Bug it is watered by the Narew, Wkra, Drewenz, and other rivers. The soil is level and fertile. The capital, Plock, on the Vistula, is one of the oldest towns of Poland; pop. 11,000.

PLOTINUS, a philosopher of the Neo-Platonic school, born in Lycopolis, Egypt, about A. D. 204, died at Puteoli in 262. At the age of 28, having a great desire to learn philosophy, he went to Alexandria, and attended the lectures of Ammonius Saccas, the founder of the eclectic school, with whom he remained 11 years. When in 242 the emperor Gordian undertook his expedition against the Persians, Plotinus accompanied the army with the intention of studying the philosophy of the East; but on the death of the monarch he barely escaped with his life to Antioch. In his 40th year he went to Rome, and there taught the doctrines of his master Ammonius, but only orally, as he had agreed to keep them secret; and although his fellow pupils, Herennius and Origen, began to publish them, he did not follow their example until the first year of the reign of Gallienus. When 10 years later Porphyry became his scholar, he had written 21 books, and at the instigation of the latter subsequently composed 24 more, to which after the return of Porphyry to Sicily he added 9. In Rome he remained until his death, and was a great favorite not only with men of science, but with senators and statesmen; and so great confidence was reposed in him, that many Romans on their death beds intrusted him with the guardianship of their children and of their estates. So much attached to him was the emperor Gallienus, that had it not been for the efforts of some of the courtiers he would have rebuilt two cities in Campania for the purpose of allowing Plotinus an opportunity of founding a commonwealth, which should be modelled after the ideal republic of Plato. He died from an accumulation of disorders at the country house of a friend. Plotinus never corrected nor read through a second time his manuscript, and paid no attention to spelling or the division of syllables. His handwriting was so execrable that, owing to a weakness in his eyes, he could scarcely read it himself; and as his thoughts were put down as they occurred and without any systematic connection, he is one of the most obscure writers to be found in any language. So conscious was he himself of this fault, that he chose his pupil Porphyry to revise his productions. These are in 54 books, called the Enneads, and treat of the most abstract subjects of thought, such as "Entity and Unity," "The Essence of the Soul," and "The Unity of the Good." According to his biographer, so ashamed was he that he existed in the body, that he would neither reveal his parentage, his ancestry, his native country, nor even his birthday. When an effort was made to have his portrait drawn, he answered: "Is it not enough to drag after us whithersoever we go that image in which nature has shut us up? Do you think that we should likewise transmit to future ages an image of that image as a sight worthy of their attention?" So great indeed was his contempt for the body, that he had no concern in regard to his health, and was very scanty in the use of food, generally refraining altogether from eating meat. Although his writings are obscure, they have exercised considerable influence upon modern philosophy, having been diligently studied by Cudworth, Henry More, Norris, Gale, and others. There is moreover a striking resemblance between the doctrines of Plotinus and the pantheistic ideas of Spinoza, evinced in the treatise of the former written to show that all being is one and the sense. His life, written by his most illustrious disciple, Porphyry, is the only authority upon his history. The Enneads were first translated into Latin by Marsilius Ficinus (Florence, 1492). In 1835 the entire Greek text was first published by Creuzer (3 vols. 4to., Oxford). The "Select Works of Plotinus" (London, 1834) have been translated into English by Thomas Taylor; and a French version of the Enneads by M. Bouillet was completed in 1861 (3 vols. 8vo., Paris).

PLOUGH, an instrument for breaking up, turning over, mixing, or loosening the soil, drawn by horses, mules, or oxen, and guided by a man who follows behind, holding the plough by the handles. Steam power has also been recently applied to ploughs. The plough of the ancient Egyptians was altogether of wood, a single crooked *stick* serving for the tail, which, extending below the point at which the horizontal beam was secured to it, formed the point or share, which was forced into the ground as the animals attached to the beam drew it forward. The share was stiffened by a rope which passed up from it to the beam, and the handle was divided so as to present a hold for each hand of the ploughman. A horizontal stick also connected the two handles by which the plough might be guided. Wilkinson thinks it probable that the point was shod with a metal sock either of bronze or iron. In the Old Testament metallic ploughshares are alluded to more than 7 centuries B. C.: "They shall beat their swords into ploughshares." (Isa. ii. 4; Micah iv. 3.) In the time of Hesiod two sorts of ploughs were in use among the Greeks. One was formed of a limb of a tree having two opposite branches diverging like the arms of an anchor from its shank. The main stem served as the beam or pole by which the plough was drawn; one arm, sometimes shod with iron or bronze, entered the ground, and by the other the implement was pressed into the ground and guided. The other was constructed of three sticks secured together by nails; one was the beam, which at its lower end was joined to the nearly horizontal share, and from this proceeded the tail or handle. The ploughs now used in Greece must be nearly or quite as simple as the ancient Egyptian plough, being made of two curved pieces of wood, one longer than the other. The long piece forms the beam, and to its lower end is secured the other stick in such a manner that one end of it passes up for a handle and the other end projects a foot or more forward of the lower end of the beam, forming the share, which is iron-shod. The share is braced by a cross bar connecting with a beam above. Virgil (Georgics, i. 169, 170) describes how the limbs of the elm may be caused by continual pressure to grow into the form of the crooked plough. In his time earth or mould boards were in use, attached to each side of the share, from which they rose bending outwardly, so as to turn to each side the soil as it was broken and loosened by the share. In some of the old Roman ploughs the colter was also introduced, being a sort of knife depending from the beam for the purpose of cutting through the soil and roots in advance of the share. Small wheels at the forward end of the beam were in use about the time of Pliny; they serve to prevent the share from entering too deeply into the ground. Among the aborigines of North and South America the plough appears to have been almost entirely unknown. The Peruvians, who were the most skilled in agriculture, employed, as described by Prescott, a rude substitute constructed of a strong, sharp-pointed stake, traversed by a horizontal piece 10 or 12 inches from the point, on which the ploughman might set his foot and force it into the ground. Six or eight strong men were attached by ropes to the stake and dragged it forcibly along, accompanied by women, who followed to break up the sods with their rakes.—Until the middle of the 18th century wrought iron was used for the parts of the plough that entered the ground, each part being rudely forged by itself with no little labor. Cast iron mouldboards were first substituted for those of wrought iron about the year 1740 by James Small, a Scotchman; in 1785 Robert Ransom of Ipswich, Eng., patented the cast iron share; and before 1790 the "land side," or that portion of the plough forming the side opposite to the mouldboard, was also made of cast iron, thus completing all the wearing parts in this material. In the United States a cast iron plough was patented in 1797 by Charles Newbold of New Jersey, and as early as 1800 such ploughs were in use near New York city, having a share and mouldboard in two parts. The construction of the mouldboard engaged in 1798 the attention of Thomas Jefferson, who wrote an elaborate article on the subject. In 1804 David Peacock obtained a patent for a plough having the mouldboard and land side of cast iron and separate, while the share was of wrought iron edged with steel. In 1818 a patent was granted to Richard B. Chenaworth of Baltimore for a plough having the 3 parts, mouldboard, land side, and share, all distinct and of cast iron. Several other patents of similar character were granted previous to the year 1820. In the most approved ploughs now in use, of the breaking-up class, the mouldboard is made of plate steel, its external surface concave and corresponding in its curve to the segment of a cylinder, of which, however, it would comprise but a small portion. Affixed to the plough with the proper obliquity, mouldboards of this character are said to turn the sod more completely and with much less friction than those of any other form. They are made separate from the share, which is also of steel or of cast iron hardened by chilling, and upon the front of this rises the colter, instead of being attached as in most ploughs to the beam a little distance ahead of the share. The breaking-up ploughs are the most important of the several sorts of this implement. They are made of many sizes adapted to the soil to be broken up, and may be drawn by one small horse, or require the full strength of 4 strong horses to carry them through the hardest gravelly soils. The depth to which they penetrate is regulated, as in other ploughs, by the contrivance at the end of the beam called the clevis, to which the draught chain is attached. This is a sort of rack or elongated iron staple, into which the chain is hooked, high up for deep ploughing, and lower down if the ploughing is to be shallow. The greatest depth reached by those of the largest size is about 18 inches, and the width of the furrow about 24. As the breaking-up ploughs are run through soil of some tenacity, as prairie or grass lands, the furrow is regularly laid flat over to one side; and as the plough comes round again another adjoining slice is laid against the former one; and so the work goes on till the whole field is covered with the long overturned slices of earth and sod laid flat or slightly lapped at different angles on each other, as the nature of the soil may require; in stiff clayey soils an angle of about 45° is best. Side-hill ploughs are breaking-up ploughs with the mouldboard so arranged that, after running through the furrow along the side of a hill, it may be instantly shifted round and secured on the other side of the plough. By this contrivance the plough may pass directly back and turn the next furrow down the slope of the hill against the one which preceded it. Another modification of the breaking-up plough is presented in the double mouldboard plough, which is designed for turning two furrows at once in opposite directions—a very expeditious mode of breaking up the ground for ditching. This class of ploughs is again modified in the variety known as the skim or Michigan plough. This has in the usual place of the colter under the beam a miniature plough, with its share and mouldboard. This, running near the surface, takes off the sod in advance of the deeper ploughing, and thus, it is found, materially diminishes the amount of draught required to do the whole work at once. Most of the modified forms of mouldboards, ploughshares, &c., are introduced with the special object of reducing the friction to a minimum and thereby lessening the amount of horse power. The beams and handles of ploughs are for the sake of lightness generally preferred of wood, though some are still made in the manner much in vogue a few years ago, especially in England, entirely of iron. Some double or triple ploughs are constructed so as to cut 2 or 3 furrows at once. The ploughs are secured in a frame at such distances apart as to turn all the ground over which they pass, leaving no untouched places. They are adapted only to light soils, and penetrate to no great depth. By reducing the size of the plough bodies and increasing their number, the implement becomes the cultivator, which is made to cut at once a number of parallel shallow furrows. For merely stirring and loosening the soil to produce the effect of hoeing, ploughs of great simplicity are in use, which are not very different from some of the ploughs of the ancient Greeks and Egyptians. One class of these, known as bull-tongue ploughs, are largely used in the southern cotton and corn fields. The share is pod-shaped, and is driven through the ground with the convex surface forward. Other ploughs specially designed for southern use, and largely supplied like the preceding from northern manufactories, are known as the rice trenching plough, the scooter plough, the cotton scraper, &c. The cheapest breaking-up ploughs for this trade are sold in New York at only $1.85 each, and the heaviest of them for cotton fields cost only $4.50. The cost of ploughs of this class for sugar cultivation varies from $4.50 to $16. The most powerful breaking-up ploughs are made for $[illegible]. Subsoil ploughs are designed not to turn up the surface, but to loosen the soil below the depth ordinarily reached in ploughing, for the purpose of admitting a freer circulation of air and moisture under and about the roots of the plants. The ploughshare, long and slender, is strongly secured to the lower end of an iron bar like a colter, which extends downward from the end of the beam to the required depth. This bar cuts through the soil without disturbing it at the surface, while below it is shaken and lifted by the passage of the share.—A form of plough called the potato plough has of late come into use for digging potatoes. In the place of the mouldboard iron bars, set about 2 inches apart, extend back 1½ or 2 feet from the share on both sides, rising up toward the plough tail. As this machine is run under the potato hills it lifts up the tubers and throws them to the surface, while the earth falls back on each side and through the bars. A trench plough of great power, invented by Mr. A. B. Allen of New York, was put in use in 1861, designed to break up and intimately mix the subsoil and surface soil to the depth of 2 to 3 feet, especially for vineyards, nurseries, plantations of forest trees, and the cultivation of crops which require a deep tilth. It is drawn forward by a strong wire rope connected with a horse whim or capstan; this is firmly secured on the border of the piece of ground to be ploughed, and is moved along this border on the completion of every half dozen furrows or thereabout.—In Sept. 1859, a practical test was made of the steam plough of Mr. Joseph W. Fawkes of Lancaster co., Penn., at the fair grounds of the Illinois state agricultural society at Freeport, Ill., and it was recommended by the committee that the first prize of $3,000 be awarded to him for its satisfactory operation. One great obstacle in the working of very heavy ploughing machines is the necessity of passing over wet and boggy places in which the wheels of the machine sink and the whole becomes immovable. To guard against this liability, Mr. Fawkes made the weight to be borne by a hollow cylinder of wood 6 feet long and 6 feet in diameter, which is set under the platform on which the engine and upright boiler are fixed. This cylinder being made to revolve acts as a driving wheel, carrying all the machinery along with it. In front of the drum is the fire box, and behind it is the water tank. In the extreme front are two iron guide wheels 3½ feet in diameter and 15 inches broad, making a steering truck, which is turned by a wheel on the platform above in charge of the engineer. The engine is of 50 horse power, and its weight with 12 barrels of water and fuel 10 tons. Its entire length is about 18 feet. The ploughs, 8 in number, are attached to a frame, which is suspended by chains passing over grooved pulleys in two beams or davits that project backward from the platform of the engine. The chains pass forward to a windlass by which the fireman may raise the whole gang up from the ground or let them down. The frame of ploughs is drawn along by other chains passing under the platform. In operation it was found that an acre could be ploughed in 12 minutes. "A strip of land 240 yards long and 20 feet wide was ploughed in 4 minutes; and the headlands of 50 feet were crossed, one in 27 seconds, the other in 30, the ploughs being elevated and lowered in the time." Its daily capacity was considered equal to ploughing 25 to 40 acres, and at an expense on the smaller amount accomplished of 64½ cents an acre, allowing for consumption of one ton of bituminous coal and one cord of wood $9, labor of 3 men $4, oil $1, wear and tear $2, and interest (10 per cent. on $4,000) $1.12. The ordinary price for prairie breaking is $2.50 per acre.—The highly cultivated soils of England are especially well suited for steam ploughing, and considerable success has attended the trials of the several methods there attempted. In some of these methods the engine moves through the field dragging the ploughs after it; in others the ploughs are under the engine platform, to which they are firmly attached; and in others the engine is stationary and draws the ploughs by wire ropes passed around drums on the engine and through pulleys secured at a distance. In 1856 Mr. Boydell exhibited at Chelmsford an engine of 8 horse power for drawing ploughs, which weighed with the water it carried 9 tons, and moved upon a portable track in pieces like an endless chain, which the wheels themselves laid, and, after turning on them, raised up to be again laid down in front. The machine was steered by a truck of two small wheels in front. It was reported capable of drawing 10 ploughs in light land at 6 inches depth at the rate of 3 miles an hour; but the ploughs are said to have been little larger than cultivators or grubbers, and the engine was unable to overcome with them any little ascent. A number of machines having the engine and ploughs all attached to the same frame have been exhibited in England. In one of these (Cousin's), described in the "Mechanics' Magazine," vol. lxix. p. 26 (1858), a series of ploughshares and mouldboards are arranged on diagonal lines proceeding from the front corners of the frame, and each of these ploughs has projecting in front of its share an Archimedean screw, which being made to revolve in the ground aids to draw the machine along while it also loosens the soil before the plough. Mr. H. M. Platt of New York has also patented a revolving screw share, which takes the place of the ordinary share, and by its revolution lifts and completely cuts up and pulverizes the furrow. Several patents have been granted in England to Mr. John Fowler, and prizes also (one of 500 sovereigns in 1859) have been awarded for his methods of ploughing by means of one or two steam engines. In the former case the engine, having two upright drums or capstans, is set at a point in the field which may be called the apex of the triangular space occupied by the apparatus. At each of the other angles is set a guide pulley through which a strong wire rope passes from one of the drums to the other, and to this rope between the pulleys the ploughs are attached. By the movement of the engine the rope is first wound around one of the drums and unwound from the other, and, the furrow being run through, the motion is reversed and the ploughs are run back in the other direction. Eight and even 12 ploughs have been worked on the single rope, half of them pointing in one direction and the other half in the other. They are attached to a frame which is balanced upon the axle of a carriage, and is moved up and down like a see-saw. The guide pulleys are moved as required to reach the unploughed portion of the field. In the use of two engines, one was placed at each end of the furrow and an endless wire rope was employed, which was passed several times around the drum of each engine, and thus the ploughs between them were drawn in either direction by their joint action. They were held in place by being attached to low trucks loaded with earth, and having thin sharp wheels which penetrated into the ground. These were easily moved along the margin across the ends of the furrows as the ploughing proceeded, but were not readily drawn sidewise from their places. For accounts of other steam ploughs, see the "Mechanics' Magazine" for 1856 and 1857.

PLOVER, the common name of the *charadriinæ*, a large group of wading birds, very generally distributed over the world. They have a moderately long and slender bill, with culmen depressed at the base but vaulted at the tip, much as in the pigeons; sides compressed, and in the groove are placed the nostrils; wings long and pointed; tail moderate, broad, and generally even; tarsi usually long and rather slender; the outer and middle toes more or less united at the base, the hind toe wanting or very small; claws compressed and curved; the head is very large, the neck short and thick, and the folded wings reach beyond the tail. The genus *vanellus* (Linn.) has been described under LAPWING.—In the genus *charadrius* (Linn.) the bill is shorter than the head, strong and straight; the 1st quill the longest;

hind toe wanting. The prevailing color is yellowish gray, spotted; the tail transversely banded; no collar on the neck; tarsi and lower thighs uniformly reticulated; legs bluish green. They are usually seen in small flocks near the sea, in the summer often going inland; the food consists of small insects, mollusks, worms, and berries, and is usually sought in the evening or at night; they are strong and rapid fliers, though for short distances, and fast runners; the note is a plaintive whistle easily imitated, as sportsmen well know; the nest is a slight hollow in the sand, lined with dried grass, and the eggs, commonly 4, are placed with the small ends together; the young leave the nest as soon as hatched; if disturbed on or near the nest, the parent birds use various devices to lead the intruder from it, pretending lameness or inability to fly. The golden plover (*C. Virginicus*, Borck.) is about 10½ inches in length and 22½ in alar extent; in the male the upper parts are brownish black, with numerous spots of golden yellow, on the upper tail coverts generally assuming the form of transverse bands; entire under parts in the breeding season black with a brownish bronzed lustre; bill black. After the autumnal moult the black of the under parts gives place to light grayish with darker spots and streaks. It is found all over North America, and in South America, N. Asia, and Europe; it is called bullhead and field plover; it breeds in the north, going south in winter. It very much resembles the European golden plover (*C. pluvialis*, Linn.), except that the axillaries in the latter are white instead of ashy; the eggs are said to be delicious, as also are the young and old birds. The dotterel of Europe (*C. morinellus*, Linn.), very common, is blackish ash with a white band behind the eyes and another above the breast; breast and flanks reddish brown, and end of tail white. Boie separated from *charadrius* the genus *ægialitis*, comprising several smaller species, with lighter and uniform unspotted plumage, with neck and head generally banded with dark, and without continuous black on the abdomen. The 5 following plovers belong to this genus of Boie. The kildeer (*C. vociferus*, Linn.) has been noticed under that title. Wilson's plover (*C. Wilsonius*, Ord) is about 7¼ inches long and 14½ in alar extent; bill 1 inch, robust; entire under plumage, forehead, and stripe over eye, white; band of black above the white one on forehead; wide transverse band on breast brownish black; upper parts light ashy brown; a ring of white around the back of neck; bill black and legs yellow. In the female there is not the black on the forehead, and the pectoral band is reddish and ashy brown. It is found on the Atlantic coast of the middle and southern states and in Brazil; it is a constant resident in the south, and breeds there, sometimes going as far north as Long island; the breeding season commences about June 1; the eggs are 1¼ by 1 inch, dull cream-colored, with a few pale purple dots and dark brown spots; it is very plump in autumn, and is excellent for the table; it feeds both by night and day. The ring plover (*C. semipalmatus*, Bonap.) is a little smaller than the last, light ashy brown above, tinged with olive; under parts, front, throat, and ring around the neck, white; a black band across the breast, extending around the back of the neck below the white ring; bill orange, black-tipped, and legs yellow; female similar, but lighter; young without the black frontal band, and the pectoral band ashy brown. It is found throughout temperate North America, and is common on the Atlantic coast; it breeds in the north, in Labrador about June 1, in rocky mossy districts in the interior; the nest is a cavity in the moss, sheltered from the north winds and exposed to the sun, near the pools formed by the melting snow; it goes south about the middle of August; the flesh of the young birds is juicy and tender; it associates with other birds of similar habits, and is not at all shy. The piping plover (*C. melodus*, Ord) is about as large as the last, but of a much lighter brown, almost ashy, the feathers with a whitish edging; there is no black band from the bill through and under the eye; the white collar around neck, and the black frontal and pectoral bands less, the latter usually not meeting in front; rump and upper tail coverts almost white; tail white at base, tipped with black. It is found throughout eastern North America, as far as Nebraska occasionally, and in the southern states; it breeds all along the sandy coasts from Labrador to Florida; it rarely goes far inland, and does not frequent rocky or muddy places. It is a very rapid flier and runner, and is so nearly the color of the sand on which it squats close when alarmed that it is hard to detect. The notes are very soft and mellow, approaching those of a song bird, whence its name. It is seldom pursued by sportsmen, on account of its small size, though its flesh is very delicate and savory. The European ring plover (*C. hiaticula*, Linn.) so nearly resembles the *C. semipalmatus* of America as to be with difficulty distinguished from it. There are about 40 other species of the genus *charadrius*.—In the genus *squatarola* (Cuv.) the bill is nearly as long as the head, strong and straight; tail long, broad, and rounded; hind toe very small, not touching the ground. Two species are described, found in both hemispheres, migrating from the temperate to arctic and antarctic regions, where they pass the warmer months; they frequent river margins and marshes as well as the sea shore, running with rapidity and uttering at the same time a shrill piping whistle; the food consists of worms, slugs, and various insects; the nest is a slight hollow in the ground lined with dry grass. The black-bellied plover (*S. Helvetica*, Cuv.) is the largest of the American birds of this group, having a length of about 12 inches. Most of the lower parts, the front of the neck, and around the tase of the bill to the eyes, are black; above white, nearly pure on the forehead, barred with brownish black on the back and tail, and tinged with ashy on the sides; abdomen, under tail coverts, and tibiæ white; quills brownish black; bill and legs black. In winter the plumage is dark brown above, spotted with white and yellow, and white below, with dark brown lines and spots on the breast. It is widely distributed over America, and along the sea coasts of most parts of the world; it migrates chiefly by night, resting and feeding by day; it is very shy except in the breeding season, which is the same as to time as in the other species. The name plover, applied to the various birds of this group, is a corruption of the French *pluvier*, derived from the fact that their flocks are in the habit of migrating during the rainy season in autumn.—The bird called the upland or field plover is Bartram's sandpiper, belonging to the sub-family *totaninæ*, and is the *actiturus Bartramius* (Bonap.), or *tringa Bartramia* (Wils.). This bird is 12 inches long; the bill is not longer than the head, curved at the tip, the cleft extending nearly to the eyes; the upper mandible is grooved for ⅔ of its length, and the feathers extend on it further than on the lower; wings and legs long; tarsus longer than middle toe; outer toe most webbed; tail more than half the wing, graduated. The general color is brownish black above with a greenish lustre, the feathers edged with ashy white and yellow; lateral tail coverts yellowish white, with black arrowheads; wide stripe over eye and under parts pale yellowish white, nearly pure white on abdomen, with brownish black lines on the neck; legs light yellow. This is the most terrestrial of the family, frequenting as its name imports the upland dry places, sometimes in the neighborhood of and at others far removed from the sea. It is spread over eastern North America, South America, and Europe, very abundant in the interior of the Atlantic states, preferring plains and cultivated fields; it is one of the few species which have not decreased with extended cultivation. It passes the winter in the vast prairies of the south-west, going in spring and summer as far north even as the Saskatchewan, returning in the autumn; it is seen in large and small flocks, and sometimes in pairs; it is very wary, a swift flier, and a rapid runner; the notes are plaintive and mellow; the food consists of beetles, grasshoppers, crickets, seeds, and berries; it is fat and juicy in the autumn, and excellent eating; the habits are the same as in the true plovers, which, though ranked among waders, rarely enter the water except on the very edge of the sea and ponds.

PLOWDEN, EDMUND, an English lawyer, born about 1517, died in 1584. He studied at Cambridge and Oxford, and in 1552 was admitted to practise physic and surgery. He then studied the common law, according to Wood; but Plowden in the preface to his "Commentaries" says that he began the study of the law in the 20th year of his age. In 1557 and 1560 he was reader, or lecturer, of the Middle Temple, and at the end of the reign of Queen Mary was made sergeant at law. He wrote "Commentaries or Reports of Divers Cases in the Reigns of Edward VI., Mary, and Elizabeth" (London, 1571, 1578, 1599, 1613, and 1816), and "Queries, or a Moot-Book of Cases, translated, methodized, and enlarged" (8vo., London, 1662). His works are regarded as the most accurate and authoritative of the old reports.

PLUM, a hardy fruit, which originated from the bullace (*prunus insititia*, Linn.), a variety of the sloe (*P. spinosa*, Linn.), and from the *P. domestica* of Linnæus. The sloe is a large, spiny shrub, or small scrubby tree with a clear stem 3 to 4 feet high; its bark is black, whence it is termed black thorn; its leaves dark green; its flowers solitary, white; the stamens, 20 to 30, have orange anthers; the style 1 or sometimes 2; the fruit a globose black drupe covered with a beautiful blue bloom when ripe. It is a native of S. Russia, the Caucasus, and the banks of the Volga, but has spread into other parts of the world. It belongs to the natural order *drupaceæ*. (See PEACH.) The bullace has spiny branches, flowers in pairs, ovate or lanceolate leaves, and roundish fruit.—The domestic plum (*P. domestica*) has spineless branches, mostly solitary flowers, lanceolate leaves, grows 16 to 20 feet high, and shows a resemblance to the sloe, though larger in all its parts. The original species and its two principal varieties have a wide geographical range, extending from Norway to Barbary, and from Portugal to Cashmere and even Nepaul. Damascus was formerly celebrated for this fruit, and the many kinds known as damsons probably originally came from there. The cherry plum or myrobalan has a handsome red globose fruit, which is depressed at base; its nut is furnished with a small point. It is a very interesting fruit, and may be regarded as the first remove from the bullace. The myrobalan is spoken of favorably as an ornamental tree, deserving a place in gardens on account of its early flowering. The apricot-like plum has the appearance of an intermediate state between the wild apricot and the wild plum; it is regarded however as a sub-variety of the domestic plum. The finer kinds of garden plums are found to vary greatly from each other in the size of foliage, earlier or later blossoming, size and shape of the fruits, and in the smoothness or downiness as well as vigor of their young shoots. The number of approved kinds, according to the latest English catalogues, is 274; the best American authorities reduce that number considerably. A large number of choice sorts have originated in the United States, and some of great size and beauty of fruit. Those known as the Lombard, red gage, golden drop, &c., with all the damsons, bear fruit well in sandy soils; while the Smith's Orleans, Washington, Duane's purple, &c., seem suited to a northern climate; and the imperial gage, Coe's golden drop, and Huling's superb are better suited to a southern. In this country the garden plums are usually propagated by sowing the nuts or stones of any free-growing kinds, and budding them with the choicer sorts when they are two years old. The seedlings of the Mirabelle plum are used when dwarf trees are wanted. The plum will grow well in almost any soil, but with some exceptions heavy loams and earths abounding in clay seem best. Muck from salt water marshes and from docks has been found very serviceable. Common salt promotes the health and luxuriance of the garden plum, and is disagreeable to insects which infest it.—The plum is liable to a singular disease, known as the black wart, which, seizing upon the young branches, ends by destroying them. From some examination we are led to think that its origin is in the too great tendency in some soils to make fruit buds, and an inadequate supply of inorganic materials in the soil to ripen and perfect the wood. This tendency causes a tumid swelling of the tender tissues, which is mistaken by the plum weevil for the fruit, stinging which to deposit its eggs only aggravates the evil; after a while the bark bursts and cracks, and a small but gregarious fungus (*sphæria morbosa*, Fries) appears upon the surface and finishes the work. The plum weevil alluded to is the *rhynchænus nenuphar* (Harris), a small coleopterous insect, which pierces the young fruits as soon as they are set, and causes them to prematurely fall, so that valuable crops are thus annually lost. The best preventive discovered is shaking the trees daily for a few weeks and catching the beetles in outspread sheets, when they must be killed. The fallen plums should be also carefully gathered up and burned.—The chief uses of the plum are for dessert and for preserving in sirups. In France several distinct sorts are raised expressly to manufacture into a sort of dried preserve called *brignoles*. The fruits are not gathered until the sun has dried off the dews; the trees are slightly shaken so that only the ripest may fall into cloths laid under them for the purpose; they are then spread in shallow baskets, which are kept in a cool and dry place. The next day the skin is removed without the use of any iron instrument, which would spoil their color, when they are dried in the sun on wooden sieves or wicker frames, after which they are threaded at the tip on little rods so as not to touch each other, and hung up to dry in the sun and air until every particle of moisture appears to be evaporated; the stones are then removed and the shape of the plum restored. After a second careful drying in the sun they are arranged in little round flat boxes and are ready for sale.—The best prunes are made of the variety known as the St. Catharine plum and the *prune d'Agen*. After being exposed in the air for several days till they have become soft, they are shut up close in spent ovens and left for 24 hours; they are then taken out and replaced after the ovens have been slightly reheated. On the next day they are taken out and turned by slightly shaking the sieves on which they have been laid. The ovens are heated again, and they are put in a third time; and after remaining 24 hours they are taken out and left to get quite cold. After some manipulation they are submitted to oven heat twice more, and then put loosely into small, long, and rather deep boxes for sale. From the bruised pulp of plums and from the kernels fermented with honey and flour, and the mass subjected to distillation, an excellent spirit is obtained in the south of France.—The sloe and bullace have both become naturalized in the United States. Four native species are also known to our flora. The Chickasaw plum (*P. Chickasa*, Mx.) is a shrub or small tree, with thin, lanceolate, acute, smooth, sharply serrate, glandular-toothed leaves; short-peduncled flowers; smooth calyx, and a yellowish red globose drupe, of ½ inch diameter, thin-skinned, and of an agreeable flavor. It is found in old fields and thickets in the southern states, but probably is only native to the country west of the Mississippi river. The wild yellow or red plum (*P. Americana*, Marshall) is a bushy tree 8 to 20 feet high, with ovate or somewhat obovate, conspicuously pointed or doubly serrate, very veiny leaves; the fruit roundish oval, ¾ inch in diameter, with a turgid stone; the skin is tough and acid, but the pulp is of a pleasant taste. This species has a wide range, along banks of streams in Canada to Georgia and Texas. It has been introduced into cultivation, and has undergone some modifications in the form and structure of its fruit. The beach plum (*P. maritima*, Wangenheim) is a low shrub with straggling branches and subject to several forms; its fruit is often an inch in diameter and pleasant to the taste, but sometimes astringent. It is peculiar to sandy coasts, ranging from Massachusetts to New Jersey; and in the variety with smaller red or purplish fruit, it reaches to Virginia and Alabama. The *P. glandulosa* (Hooker) has been noticed in Texas by Drummond, having a stem less than one foot high and very crooked thorny branches, small oval, obtuse leaves, and umbels of 1 or 2 flowers, but with unknown fruit. Some other species of plums have been described by Thunberg and others as natives of Japan, China, &c., but little is known regarding them.—The wood of the plum, especially of the wild species, is hard, and bears a polish, but is apt to crack, and fit chiefly for handles to tools and for walking sticks. The spiny branches of the sloe are used for dead hedges and to protect the stems of valuable trees from cattle. Its leaves dried make a substitute for tea, and all kinds of domestic animals are fond of them; the bark is used as a febrifuge, and the fruit is styptic; the bark also has been used in tanning; a decoction of it in alkali dyes yellow, and in sulphate of iron it forms a beautiful black ink; its unripe fruit has been pickled as a substitute for olives, but the flowers are purgative. The gum of the common plum tree resembles tragacanth.

PLUMB LINE, or PLUMMET (Lat. *plumbum*, lead), an instrument consisting of a weight, usually of lead, hanging to a string, used by artificers and others to fix vertical lines, or more correctly those in the direction of terrestrial gravity. This instrument was in use by the ancients, and is referred to in the books of Amos, vii. 7, 8, and Isaiah, xxviii. 17. One limb of a carpenter's square being set in a vertical position by a plumb line attached to it, the other limb must be horizontal; and so the instrument may serve to determine horizontal as well as vertical lines. By means of a quadrant scale between the two legs of the square and a plumb line suspended from the central point of junction, angles of inclination of the surface upon which the instrument stands from the horizontal or vertical may be read. In surveying and astronomical instruments the plumb line is sometimes used as a means of fixing and regulating their position, but the spirit level is generally employed instead.

PLUMBAGO. See GRAPHITE.

PLUMER, WILLIAM, an American politician, governor of New Hampshire, born in Newbury, Mass., June 25, 1759, died in Epping, N. H., Dec. 22, 1850. When he was only 8 years of age his family removed to Epping, and in that place he lived until his death. He was admitted to the bar in 1787, became speedily successful as a lawyer, and for many years took an active part in the political movements of New Hampshire. He was 8 times elected a representative to the state legislature, of which he was speaker for two years, and subsequently he was a member and for two years president of the state senate. In 1792 he was one of the delegates to the convention for revising the constitution of the state, in the proceedings of which body he bore a prominent part. In 1802 he was elected to the U. S. senate, and in 1812, 1816, 1817, and 1818 was chosen governor of New Hampshire. In 1820 he was a presidential elector, which was the last public office he filled, as from this time he devoted himself to literary pursuits. He contributed largely to the periodical press, but otherwise published little, although he left many manuscripts.—A life of Gov. Plumer has been written by his son, William Plumer, jr., and edited by the Rev. A. P. Peabody, D.D. (8vo., Boston, 1856).

PLUNKET, WILLIAM CONYNGHAM, baron, an Irish lawyer, born in Enniskillen in July, 1764, died Jan. 4, 1854. He was the second son of a Presbyterian minister, who removed to Dublin while William was still young, and dying soon afterward left his family to the care of his congregation. William was graduated at Trinity college, Dublin, obtained a scholarship, entered Lincoln's Inn in 1784, and was called to the Irish bar in 1787. His professional progress was slow, but he became king's counsel in 1798. When the rebellion broke out he gave professional aid to the patriots, and was publicly accused of being an associate in their proceedings, but the charge was disproved. He entered the Irish parliament in 1798 as member for Charlemont. He opposed the legislative union with England in 1800, and his speeches in the debates on that measure raised him to the first rank of his party; they also greatly increased his practice at the bar, to which he returned when the union was accomplished. In 1803 he was made solicitor-general for Ireland, and on the outbreak of Emmet's rebellion was selected by the crown as one of the lawyers for the prosecution. His speech on that occasion exposed him to much obloquy, and to the abuse of Cobbett, whom he successfully prosecuted upon a libel suit. In 1805 he was made, by Pitt, attorney-general for Ireland, and was continued in that position under Lord Grenville. He held a seat in parliament during the same period, and made several able speeches in favor of Catholic emancipation. On the dissolution of the ministry in 1807, he retired, but in 1812 reëntered parliament as member for Trinity college. He was again made attorney-general for Ireland in 1822, and one of his first official acts was to prosecute a large number of Orangemen for riot. Made master of the rolls in England in 1827, he was compelled through the jealousy of the English bar to abandon the office, and soon after was elevated to the post of chief justice of the common pleas in Ireland, and was ennobled. In 1830 he was appointed lord chancellor of Ireland, and held the office, except for a brief interval, until 1841, when he finally retired to private life.

PLUSH (Fr. *peluche*), a textile fabric distinguished by its velvet nap or shag on one side. It may be entirely of worsted, or of cotton, or silk; but it is usually composed of a woof of a single woollen thread and a twofold warp, the one wool of two threads twisted, the other goats' or camels' hair. As the hair warp is raised by one treadle and the woollen warp is depressed by the other two treadles, the woof is passed between. Afterward the hair warp is cut with a fine-pointed knife, thus producing the velvety appearance. Plush is especially a French manufacture, though it was long since made by the English and Dutch.

PLUTARCH, a Greek biographer and philosopher, born in Chæronea in Bœotia. The little that is known of his life has been collected chiefly from his own works. He was studying philosophy under Ammonius at Delphi when Nero visited Greece in A. D. 66. He also visited several parts of Italy, and remained for some time at Rome, where he lectured during the reign of Domitian. It is probable that he spent the later years of his life at Chæronea, where he says that he wrote the life of Demosthenes. Here he discharged the duties of a magistrate, and was also a priest of Apollo. He was married to a lady of his native city named Timoxena, and had 5 children, to one of whom, Lamprias, is attributed the catalogue of his productions. The statement of Suidas that Plutarch was the preceptor of Trajan is probably unfounded. Of the time and manner of his death we have no knowledge, although it is certain that he lived to an advanced age. Fabricius conjectured that he died when 70 years old, in the reign of Hadrian. The great work of Plutarch is his "Parallel Lives." In this he writes a biography of a Greek and of a Roman, and then makes a comparison between the two, although in some cases the comparisons are now lost. There are 46 of these lives extant. The other works ascribed to him, numbering about 60, are ranged together under the general title of *Moralia*, but 11 of them are on historical subjects. Some of these essays were probably not written by Plutarch. His "Lives" he himself preferred to his other works. The first edition of the "Lives" in the Greek text appeared at Florence in 1517, and the latest and best is that of C. Sintenis (4 vols. 8vo., Leipsic, 1839–'46). Of the numerous translations of the work, the excellent French one of Amyot was rendered into English by Sir Thomas North in 1612. Dryden's translation is really the work of other hands, the poet himself having written scarcely any thing but the dedication to the duke of Ormond, and the life of Plutarch. There is another English translation by John and William Langhorne. A revision of Dryden's has been edited by Arthur Hugh Clough (5 vols. 8vo., Boston, 1860). The first edition of the *Moralia*, very incorrect, was that of the elder Aldus (fol., Venice, 1509). The best is that of Wyttenbach (8 vols. 4to., Oxford, 1795–1821). It has been translated into French by Amyot, into German by Kaltwasser, and into English by Howard (London, 1603). The first edition of the complete works is that of H. Stephens (13 vols. 8vo., Geneva, 1572).

PLUTO, in ancient mythology, the god of the lower world, usually known in Greek mythology as Hades. He was a son of Saturn and Rhea, and was brother of Jupiter and Neptune; and when the world was divided among the three, he obtained for his share "the darkness of night." His wife, called by the Greeks Persephone and by the Romans Proserpine, was the daughter of Ceres, and was violently carried from the upper world. Of all the gods, he was the most hated of mortals, and his temple and statues do not seem to have been numerous. In Homer he is always called Hades, but among the later Greek writers that term came generally to be applied to the abode of the dead itself. By the Roman poets Dis, Orcus, and Tartarus are used as synonymous with Pluto.

PLUTUS (called also Pluton), in ancient mythology, the god of wealth. He was the son of Jasion and Ceres, and is said to have been blinded by Jupiter so that he might distribute his gifts without regard to merit, he having previously granted them to the good exclusively. When coming to mortals he is slow-footed and lame, when going from them swift-winged. He appears to have been usually represented as a boy with a cornucopia.

PLYMOUTH. I. A S. E. co. of Mass., bordered E. by Massachusetts bay, and S. partly by Buzzard's bay, and watered by Taunton and North rivers; area estimated at 700 sq. m.; pop. in 1860, 66,784. Its soil is not fertile. The agricultural productions in 1855 were 139,617 bushels of Indian corn, 231,865 of potatoes, 19,948 tons of hay, 8,628 lbs. of wool, and 399,878 of butter. The coasting trade and fisheries occupy much of the industry of the county. In 1855 there were 18 vessels of 3,519 tons engaged in the whale fishery, and the receipts of oil were: whale, 45,108 galls., value $33,831; sperm, 108,756 galls., value $188,291. The mackerel and cod fishery employed 96 vessels of 7,368 tons, returning 12,555 barrels of mackerel, and 39,792 quintals of codfish. There were 5 cotton mills, 20 forges, 23 rolling, slitting, and nail mills, 18 furnaces for hollow ware and castings, 12 tack and brad factories, and 33 establishments for the manufacture of rail cars, coaches, and other vehicles. In 1858 there were 127 churches and 6 newspaper offices. The Old Colony and Cape Cod railroads, beside branches, give the county extensive communication with the large cities of New England. Capital, Plymouth. II. A N. W. co. of Iowa, bounded W. by the Sioux river, and intersected by Floyd river; area estimated at 850 sq. m.; pop. in 1859, 112; productions in 1859, 400 bushels of wheat, 865 of oats, 11,125 of Indian corn, 2,625 of potatoes, and 317 tons of hay.

PLYMOUTH, the shire town of Plymouth co., Mass., 37½ m. S. E. from Boston by the Old Colony railroad; pop. in 1860, 6,274. The township is one of the largest in the state in point of area, extending on the coast about 16 m. from N. to S. Plymouth village is situated at the N. end of the township, and is compactly built, chiefly of wood. It is a port of entry, and the harbor is formed partly by a beach 3 m. long, which extends N. and S. and protects it from the waters of Massachusetts bay. The harbor is large, but shallow. A considerable number of trading and fishing vessels are owned here. The manufactures of the town are of more importance than the coasting and fishing trade. They consist of cotton goods, as cloth, duck, and thread; iron ware, as hoops, nails, rivets; cordage, of which the factories are extensive; sails, boots and shoes, articles of clothing, &c. The most noted edifice is Pilgrim hall on Court street, built in 1824–'5, which contains a large hall and curiosities relating to the pilgrims of the Mayflower and other early settlers of Massachusetts, together with historical paintings, and portraits of distinguished citizens. Among the antiquities is a chair that belonged to Gov. Carver, the sword of Capt. Miles Standish, and a variety of aboriginal weapons and implements.—Plymouth is the oldest town in New England. The pilgrim fathers landed here Dec. 11, 1620, O. S., on a granite bowlder lying on the shore, near which it has been proposed to erect a monument, the corner stone of which was laid Aug. 1, 1859.

PLYMOUTH, a fortified seaport of Devonshire, England, situated at the head of the sound of the same name, on the river Plym, 220 m. W. S. W. from London; pop. in 1871, 52,221. Taken in its widest sense, the name comprehends what are called the "Three Towns," viz., Plymouth, Devonport, and Stonehouse. Plymouth proper is a very thriving and handsome town, covering about 1 sq. m. of ground. The royal hotel is an extensive structure with a theatre and assembly rooms attached, erected by the corporation of the town at a cost of £60,000. In the Cottonian public library there are many rare and valuable works, a large collection of MSS., paintings, drawings, &c. The place owes its celebrity to its fine harbor and dockyard. (See DEVONPORT.) It is supplied with water brought from Dartmoor by a channel 24 m. long. The manufactures, with the exception of those connected with the naval establishments, are of little importance. The fisheries are very productive.—Plymouth was a place of some importance in 1438. The British fleet rendezvoused here at the time of the threatened invasion of the Spanish armada; and the port equipped 7 ships and a fly boat as its share of the fleet. It sided with the parliament against Charles I., and was several times unsuccessfully besieged by the royal forces. It returns 2 members to parliament.

PLYMOUTH BRETHREN, a Christian denomination which arose a little more than 30 years ago in Great Britain. Among its early prominent leaders was John Darby, an Anglican clergyman, after whom the members of the denomination on the continent of Europe have frequently been called Darbyites. From a doubt as to the apostolic succession in the church of England, Darby proceeded to reject altogether the idea of a still legally existing Christian church, and maintained that Christians of like opinions should gather together in small bands to prepare for the second advent of the Lord, which Darby hoped he would live to see. The Brethren have no written creed or confession, and every one is allowed entire freedom of belief; yet they hold the total depravity of man, the necessity of regeneration by the Holy Spirit, and the atonement by the sufferings and death of Christ. They reject all special designation or ordination to the office of the ministry, but regard all true Christians as priests, who, if they are found able to edify the brethren, are authorized to preach and administer the sacraments without any human call or ordination. As a body, they practise adult baptism only; they do not make it a condition of membership, yet generally succeed in convincing their members of the importance of being rebaptized. Their worship consists simply in adoration, praise, and thanksgiving to God. They partake of the Lord's supper every Sunday morning, and believers only are expected to meet then. In the afternoon or evening of the Lord's day they preach to such as are not yet converted.—The Plymouth Brethren spread first through Great Britain, and particularly in the town of Plymouth, where they gained perhaps 1,500 believers; hence the name. They soon became divided into three parties. At the head of one of them was Darby; at the head of a second Newton, whose peculiar doctrines respecting the person of Christ were generally repudiated by the denomination as heretical, and afterward retracted by the author. Among the other congregations which refused to be involved in the bitter personal controversies between Newton and Darby, the Bethesda congregation of Bristol was prominent. The leader of this congregation, George Müller, is the author of the well known autobiographical work, "The Lord's Dealings with George Müller," republished in America, with an introduction by Dr. Wayland, under the title of "A Life of Trust" (Boston, 1861). Notwithstanding their internal divisions, the Plymouth Brethren have of late been making great progress in Great Britain, and in 1860 a revivalist of some note, the Rev. Mr. Guinness, was baptized by one of their leading men, Lord Congleton. In 1850 they had 132 places of worship, which number, we believe, has since been considerably increased. At present gatherings of them exist, varying from a small number to many hundreds, in most of the cities and large towns of England, Scotland, and Ireland, also in remote country districts and villages.—Darby was induced in 1838, by the opposition which he met in England, to remove to Switzerland. He gathered a number of adherents in almost every town of the canton of Vaud, and in several towns of Geneva and Bern. A French periodical, *Le témoignage des disciples de la parole* (afterward called *Études scripturaires*), was started for the propagation of their tenets, and a kind of seminary established for training missionaries. They suffered some losses from the political revolution in the canton of Vaud in 1845, and later from the organization of a free reformed church; yet they still have congregations in most of the towns of Vaud, of which the most numerous are those of Lausanne and Vevey. From Switzerland they spread into France, where they have congregations in Paris, Lyons, Marseilles, and a number of other places. They have been still more successful in Italy since 1848, where nearly all the numerous so called free evangelical associations, under the leadership of Dr. De Sanctis, Professor Mazzarella of Bologna, Count Guicciardini, and others, have adopted their principles to a greater or less extent. A few scattered congregations are found in Germany, at Cape Colony, in Australia, New Zealand, and Canada. They made their appearance also in the East Indies, where Bishop Wilson of Calcutta published a pastoral letter against them. In the United States there are gatherings in Philadelphia and various other places. Here also dissensions have shown themselves; in Philadelphia, for example, there is a second meeting, not recognized by the others, on account of holding views on the non-eternity of future punishment which the Brethren generally consider heretical. A full account of the dissensions among the Plymouth Brethren of England is given by Estéoule, *Le Plymouthisme d'autrefois et le Darbyisme d'aujourd'hui* (Paris, 1858). The best, though very brief, sketch of their origin, rise, and progress, of their present condition and principles, and of the literary productions of the denomination, may be found in Mrs. H. Grattan Guinness's "Answer to the Question: Who are the Plymouth Brethren?" (Philadelphia, 1861).

PLYMOUTH SOUND, a large inlet of the English channel, situated about 12 m. N. N. E. from the Eddystone lighthouse, 3 m. wide at the entrance, and extending inland about the same distance to the town of Plymouth. The coast is generally rocky and abrupt, and the rocky island of St. Nicholas rises out of the water at its head, near the N. shore. On the W. side is Cawsand bay; and further up in the N. W. corner of the sound is the estuary of the Tamar, which is called Hamoaze, and forms the harbor for the ships of war. The estuary of the Plym or Laira forms another harbor, which is called Catwater; it is capable of containing 1,000 sail of ordinary vessels, and is generally used as a harbor for merchant ships and transports. The Catwater opens into the N. E. corner of the sound, and is not so deep as Hamoaze. There are both wet and dry docks connected with it. Sutton pool is a tide harbor, also used by merchant vessels; and a pier at Mill Bay accommodates the largest steamships at all states of the tide. The harbor of Hamoaze is 4 m. long, has moorings for nearly 100 sail of the line, and 15 fathoms of water at ebb tide. An extensive breakwater protects the sound against gales from the southward. (See BREAKWATER.)

PNEUMATICS (Gr. πνεῦμα, wind, air), that branch of general mechanics which treats of the equilibrium and motion of elastic or aëriform fluids, *i. e.*, of gases and vapors. Many portions of this subject being embraced and treated under special topics, as ATMOSPHERE, BALLOON, BAROMETER, DIVING BELL, WINDS, &c., a statement of the general theory only, with such applications as are not elsewhere made, will here be in place. The fact that air is material, and of course that all similar bodies are so, as truly and in the same sense as water or iron, is one that requires to be admitted and kept in view from the outset. It may be mentioned, in illustration of the materiality of air and other gases, that in running, swinging the hand, or standing in a wind, we become sensible of the contact of the air. Any one attempting to run, drawing after him an open umbrella, with the concave side toward him, will become convinced that, however imperceptibly air glides out of our way in our ordinary movements, making room without apparent resistance, it is in reality a material mass, possessing considerable density, having the property of inertia in common with all matter, and actually opposing resistance to all efforts which directly tend to impart motion to it. Many gases, as the air, are permanent, preserving their gaseous form under all degrees of temperature or compression to which they have yet been subjected. Other gases, as chlorine and ammonia, are by the agency of cold and pressure caused to change their state, becoming liquids or solids, and for the time, of course, losing the peculiar properties of the aëriform condition; these are non-permanent gases. By like agencies, all vapors proper are made to return to the liquid form. As ordinarily understood, pneumatics treats of the action only of bodies in the form of the permanent gases, of which common air is conveniently taken as the representative; and vapors in the perfect or "dry" state, as invisible steam, before condensation has begun to charge them with moisture and diminish their expansive force, as well as the liquefiable gases when above their point of liquefaction, belong to the same class, and follow the same laws. But the principles of this science can be so extended as to investigate the elasticity and action of the vapors and non-permanent gases, through all stages of condensation, down to the liquid condition. Unless when otherwise stated, the principles which follow will relate to the permanent gases only, air being taken as the common type.—The distinguishing characters of these bodies grow out of the facts that their molecules do not sensibly cohere, but can move with perfect freedom both about and away from each other; and that between these molecules there exist repulsive forces greatly exceeding any forces of attraction that may act, causing them at all times to strive to recede from each other, and with considerable energy. From these circumstances it follows: 1, that all gases can be compressed, or if allowed will expand, and so far as yet known, in the case of perfect gases, these results take place to an indefinite extent; 2, that, when compressed, a perfect gas will always exert a pressure in the contrary direction, or against the compressing force, thus manifesting the peculiar form of elasticity possessed by these bodies, or what is called their expansive force, and the measure or amount of which for a given case is termed the tension of the gas or vapor; 3, that, wherever a gas or vapor is found to exist as a body, having appreciable density, this is invariably the result of some confining pressure applied to it from without, and compelling its particles into a certain degree of proximity; 4, that when a body of gas is kept from expanding, this is because the pressure from without equals and balances its tension at the time; and 5, that when a body of gas is at rest throughout all its parts, this is because, at every point within it, the various pressures exerted in different directions are in equilibrium. The difference ween liquids and gases in the last respect is, in a body of the former, at rest, there is uilibrium at every point between an applied essure by weight or otherwise, and reaction an incompressible mass; but in the gas the uilibrium is between an applied pressure and e repulsive force or tension from within. eat, increasing this repulsion, augments the nsion; and unless a correspondingly greater ternal pressure is then brought to bear, the uilibrium is destroyed. If this take place at point within the gaseous body, the result is a inging or current; if exerted throughout its tire volume, the pushing out of the enclosing rriers by expansion. Illustrations of these nciples are numerous. If a little air only be rfectly enclosed in an India rubber bag, and at continuously applied, the tension and volume the enclosed air are so increased as to swell , or even to burst the bag. The same results y be secured in a precisely opposite way, by acing the bag, prepared as before, in the reiver of the air pump, and gradually exhaustg, *i. e.*, reducing the density and tension of e confined atmosphere about the bag; the mpressing force on the enclosed air being us lessened, the tension of this body of air in excess, and expansion follows, going on till this tension is so lowered as to equal the m of the outer pressure and the cohesion of e rubber, or until the latter gives way. So, e atmosphere is a confined and compressed dy of air, gravitation holding and squeezing down to a stratum of moderate depth, over e earth's whole surface. But in any body gas so situated, though rigidly under this nfining pressure, the particles will still posss complete freedom of motion about each her; and any diminution or increase of presre at points within the mass will be followed currents, such as winds; in other words, twithstanding any degree of compression om without, such a body is still perfectly uid. Now, the fundamental laws of the rest d motion of liquids are consequences, not of eir property of liquidity, but of their fluidity. ence, with such modifications as are required the want of cohesion in the gases, their mpressibility and expansive force, all the laws hydromechanics become strictly true also for riform bodies—the same principles which perate in the ocean (of water) or in the essel of water, also having place in the aërial cean or in the enclosed volume of perfect apor. Among these may be named: 1, hat equal pressures in every direction are erted upon and by every point in a gaseus body at rest; 2, that a pressure made on confined body of gas, as in a liquid mass, perfectly transmitted in every direction, and the atmosphere to great distances; 3, that ch pressure is proportional to the area of surce receiving it, and so multiplied when the ceiving surface is larger than that communiting it; 4, that pressure on a given surface a given depth, due to weight, is calculated in a similar way; 5, that the free surface of any such body, as the upper aërial surface, tends to a level at any place; and 6, that within any body of gas, at any given depth, there is exerted a supporting *or* buoyant power, which is as the density or tension of the gas at the place. The difference in the two sets of cases is, that while liquids balance by simple pressures, gases and vapors always balance by their tensions. Even the hydrostatic paradox finds its counterpart in the case of gases; any quantity of the latter, however small, balancing any other quantity, however great, so long as the tensions of the two are equal. Thus it is that, so long as the elasticity of the included equals that of the surrounding air, the vast mass of the atmosphere does not overbalance the minute body of air in the lungs, nor the still less collections of air distributed through our tissues, and so act upon these as to compress them and destroy the organs. And the whole mechanical operation of breathing is simply a flux and reflux of so much air as will restore the equality of tensions, or equilibrium, of the air within and without the lungs; such equilibrium, however, being, under nervous and muscular action, as often disturbed again by enlargement and diminution of the cavity of the thorax. Man is permeated by his atmosphere, and like all animals fitted to exist only in a stratum extending between certain limits of density. If he ascends from ordinary levels to the height of 2 or 3 miles, the outer tension becomes deficient, and the fluids of the body rupture their enclosing vessels outward; if he descends to great depths, the outer tension preponderates, and the air cells of the lungs or other membranes are burst inward, or the pressure causes congestion within the unyielding walls of the cranium. So, upon explosion of the large amount of powder in a mill or magazine, the superincumbent air being lifted upward, that in the vicinity is rarefied, and houses situated in this portion, if closed, often have their windows burst outward by expansion of the air within them. Air could be substituted for water in the hydrostatic press, and with the same gain of power, were it not that its compressibility enables the load as well as the power to descend upon it, so that a part of the work is lost in producing compression.—Aristotle asserted that air has weight, and suggested, though in an impracticable form (the use of a bladder of air), the experiment by which this truth was finally established. Many subsequent writers supposed in a general way that air is heavy, and thus explained such facts as the difficulty of raising the piston of a syringe when air is not allowed to enter it. Galileo still more clearly conceived of the air as a ponderable mass, and proceeded to adduce some of the hydrostatical principles already referred to. Torricelli proved the weight and pressure of the air, and measured its amount, in the experiment which led to the construction of the barometer (1643); and Pascal confirmed these results by showing that at heights above the ordinary level the mercurial column supported by the air is shorter (1647). The weight of a column of air resting on a horizontal square inch, at the sea level, is, at an average temperature, very nearly 14.6 lbs.; and a pressure of this amount is conveniently termed a pressure of one atmosphere. The first pneumatic law, investigated by Boyle in 1650, and by Mariotte in 1676, and known as Mariotte's law, affirms that, at a given temperature, the volume of an aëriform body at rest is inversely as the compressing force. Direct consequences are, that the density and the tension are proportional to the compressing force. The second great law of tension and pressure is that of Dalton and Gay-Lussac (1801), by both of whom it was independently discovered, according to which, when the tension of a gas or vapor is constant, the density diminishes as the increase of temperature; in other words, for equal increments of temperature, a gas or perfect vapor expands by the same fraction of its own bulk; this being $\frac{1}{480}$ of its volume at 32° F., and for each degree above that point, or about $\frac{3}{8}$ of its volume between 32° and 212°. Amontons compounded the ratios given by these two laws, obtaining a third, which expresses the relation of tension to temperature, when the density is constant. Professor Potter (1858) adds a fourth, an empirical law, for cases in which the quantity of heat remains constant; namely, that in any sudden condensation or rarefaction, the difference of temperature varies as the cube of the rarefaction. Of air, or any other permanent gas, the tension remains unimpaired under compressing force applied for any length of time. It was found, however, not long after the announcement of the laws of Mariotte and Dalton, that vapors and nonpermanent gases undergo compression in a ratio greater than that of the increase of pressure upon them, and that near the point of condensation this deviation becomes very great. More recently, Mariotte's law has been found to need still further qualifications. Despretz (1829) announced that carbonic acid, ammonia, cyanogen, and some other gases, undergo at all temperatures a compression more rapid than that of the increase of pressure, and in a ratio uniformly increasing; while above 14 atmospheres the result with hydrogen was the opposite. Regnault has confirmed these results, and has even shown a deviation from the law in the case of a confined body of pure air. He obtained, for instance, a 10 and 20 fold density of air by applying respectively 9.9 and 19.7 atmospheres of pressure; of carbonic acid, by 9.2 and 16.7 atmospheres; of hydrogen, by 10.05 and 20.26. The slightly different results since obtained by Natterer are regarded as less trustworthy. It follows that Mariotte's law is to be accepted as but approximately true, the variations being different for different gases; but the deviation, especially in air, is so slight, that for ordinary determinations of the volume of gases, and in the use of air in manometers or pressure gauges, it may be overlooked. Such gauges are of two kinds, according as the intention is to estimate rarefaction or increased density in a confined body of air, steam, &c.; the former being called vacuum gauges, the latter condensing gauges. Essentially, the simple manometer, in either form, is but a tube, straight or bent, containing a column of mercury, the space at one extremity of which is in communication with the enclosed gas or vapor. Above the other extremity, if the object be to measure rarefaction, the atmosphere is allowed to press, or a vacuum is left; rarefying the enclosed body, the column of mercury falls by reason of diminishing support or preponderance of the outer air, and the amount of descent shows, on a prepared scale by the side of the tube, the degree of rarefaction. The straight vertical column of mercury supported by the atmosphere, being about 30 inches in height, a descent of 1 inch shows the subtraction of $\frac{1}{30}$ of the density and tension of common air; and this quantity is conveniently spoken of as "1 inch of pressure," or "1 inch of mercury," half the atmospheric tension being 15 inches of pressure, and so on. In the condensing gauge, the confined body of air in the outer end of the bent tube is of course compressed to half its volume, that is, in a uniform tube, to half its length, when the tension within the engine or apparatus is 2 atmospheres; to one fourth, when it is 4 atmospheres; and so for any number of parts, as shown by a scale. The earth's atmosphere being subject to compression by its own weight, it results, as stated more at length in the article ATMOSPHERE, that at heights in it increasing in an arithmetical ratio, the density and tension diminish in a geometrical ratio. Now, all the relations expressed in Mariotte's law and its consequences are conveniently exhibited in a table like the following; and by including the last column, that of heights, the 0 of heights being the sea level, and the height 1 denoting that experimentally found as 2.705 miles, all the relations in the first 4 columns become represented as they exist theoretically, and very nearly actually, in our atmosphere:

Pressures.	Densities.	Tensions.	Volumes.	Heights, in the air.
1	1	1	1	0
1/2	1/2	1/2	2	1
1/4	1/4	1/4	4	2
1/8	1/8	1/8	8	3
1/16	1/16	1/16	16	4
...	...	...	...	..
1/1024	1/1024	1/1024	1024	10
&c.	&c.	&c.	&c.	&c.

In the atmosphere, however, other causes of slight deviation from the relation of density to height exist. Among these are: 1, that the earth's attraction diminishes somewhat, about $\frac{1}{2000}$ part for each mile near the earth, at points taken in ascending through the atmosphere; 2, that the attractions of the sun and moon at some times and places conspire with, at others

pose, the action of the earth; 3, variations
e to changing temperatures; 4, admixture
vapors, &c., in the lower atmosphere. The
neral effect is a slightly more rapid diminu-
n of density than that above given, with
crease of altitude. Exemplifications of the
nets of equilibrium, and of disturbance of
uilibrium in bodies of gas or vapor, and of
e relations of tension to volume expressed
Mariotte's law, are numerous, and in view
these principles very readily understood.
hus, upon the large tanks inverted and dip-
ng beneath in water, called gasometers, em-
oyed at gas works for containing the illumi-
ting gases to be distributed, any increase of
essure is applied, this pressure is speedily
t throughout the bodies of the fluid filling
e mains and service pipes, branching in all
rections and miles in length, and from the
ousands of burners in which these pipes ter-
inate the gas jets with increased velocity and
lume. The action commonly called suction
is in all cases purely mechanical. Performed
y the mouth, the air in its cavity is first partly
pelled, and the cheeks dilated, while ingress
f more air through the mouth and nostrils is
revented; hence, the body of air included
ithin the mouth, and between it and the sur-
ce to which the suction is applied, or, in case
f raising a liquid, that also in the tube reach-
g from the mouth to the liquid, is considera-
y rarefied; its tension diminishes in propor-
on, the external air preponderates, and the
rface or liquid is impelled toward the mouth;
it be a liquid, by repeating the operation, a
ntinued flow, though not to a greater eleva-
n than about 32 feet, is secured. With this
ew and explanation that of the common
mp is identical. In the exhausting syringe,
tight piston ascending through a cylinder,
hich is below in communication with a con-
ed body of air, enlarges the space presented
the air, and this expands to fill the whole
ace; by the action of valves opening out-
ard, the portion entering the cylinder is ex-
lled. The air pump, in its most perfect con-
uction, is no more than such an exhausting
ringe, in a form and with additions securing
e greatest convenience of use. The pro-
ss of cupping depends on the pressure of the
ernal atmosphere, which forces a portion of
e fluids of the body, chiefly blood, into the
rtial vacuum in certain ways secured in the
pping glass. The siphon, the pneumatic ink-
and, and the pneumatic bracket, alike be-
me serviceable through the pressure of the
r. The balloon is rendered practicable by
e equal upward pressure, or buoyancy, which
fluid, experiencing at any given depth a cer-
in downward pressure (in this case, its
eight), must exert. The numerous instruc-
ve or amusing experiments made with the
r pump, including that one so famous in the
story of the sciences, because so efficient in
lightening the public mind in regard to the
eat truth of atmospheric pressure, namely,
that of the Magdeburg hemispheres, are all but illustrations of, and very obviously explained by, principles such as those now presented. In Hero's fountain, a condensation of air going on by the influx of water into one vessel, is made by increase of tension to cause a jet of water from another vessel with which the former communicates. The action of the bellows, of fan wheels and blowing machines, for furnaces, ventilation, &c., may be understood upon simple pneumatic principles; and the phenomenon of intermitting springs is supposed to be due to the presence of a siphon-shaped conduit leading from a cavity within elevated ground to the point at which the spring emerges. The phenomena of natural circulation of air through mines by means of two upright shafts of unequal length, hence containing atmospheric columns which, through difference of temperature within the shafts, are of unequal weight, as well as the draught of chimneys, ventilation in all its forms, the land and sea breezes, and indeed all winds, are obvious examples of currents due to a disturbance of the atmospheric equilibrium at given places. The causes leading to such disturbance, in the latter cases, are considered under METEOROLOGY.—Aëro-dynamic problems, or those investigating the flow and delivery of gases through orifices, in tubes, and in currents, and the consequences of the impact and momentum of moving air, are of too intricate a character to be presented fully except in special treatises on the subject. Torricelli's principle for liquids, that the velocity of discharge from an orifice is that which the body of liquid would acquire in falling freely from the height of its surface to the orifice, applies quite as strictly to gases as to liquids. Now, a heavy body, in falling through one foot, acquires a velocity of 8 feet per second; and the velocities of discharge being as the square roots of the depths, and the height of the surface of a homogeneous atmosphere above the sea level being 27,720 feet, it follows that, at the latter level, the velocity with which air should jet into a vacuum through an opening not too small, will equal nearly the product $8\sqrt{27,720}=1,332$ feet. Experiments show that the actual velocity, as in the case of water, is somewhat less; that for orifices in a thin wall it is about 65 per cent. of that named; for short cylindrical spouts, .93; and for conical, narrowing outward, .94. These facts correspond in a degree with the results in spouting liquids, and show that, as well as in these, the "contracted vein" exists in the efflux of gases. The movement of gases through pipes is also subject to retardation similar to that affecting the delivery of liquids; and roughness of the inside of tubes, sharp angles, inequalities of size, &c., here also increase the amount of retardation. This retarded flow has proved, unexpectedly, a chief difficulty in the way of using the pneumatic power transmitter proposed by Papin—in substance a hydrostatic press containing air, with

a long pipe connecting the two pistons, so as to allow of action at distant points. So, in the case of a blowing tube constructed in Wales to catch the air impelled by a waterfall, and convey it to a distance, in order to feed the blast of a foundery, the time estimated for the delivery of the air being 6 seconds, it was found that the jet of air did not arrive until after the lapse of 10 minutes; and being then but feeble, the plan proved worthless. The remarkable retardation of gases in tubes must be due in a considerable degree to adhesion of the gases to the solid surfaces, a principle well known; and Robison has also supposed much of it due to an undulation arising from this and other causes in the transmitted air. It is well ascertained that, beside varying in the force of horizontal movement, producing gusts, winds also undulate vertically, as do water waves. Moreover, winds are retarded by obvious causes near the surface of the earth, just as a stream of water flows slowly at its bottom; and thus they are always less violent in cities than in the open country. Similar influences must modify their flow at the sides, and above, and especially where winds flow in unlike directions along an aërial plane dividing them.

PNEUMONIA, Peripneumonia, or Lung Fever, inflammation of the proper substance of the lungs. Pneumonia is one of the most frequent forms of inflammation; it is common to all ages, attacking equally the old man and the newly born infant. It prevails more frequently in spring and autumn than in summer and winter, in cold and temperate than in tropical climates. The prolonged exposure to cold is the cause to which it is most frequently attributed, but in many instances careful research cannot assign an exciting cause; it occurs oftenest among the ill fed, the intemperate, and those who suffer from crowding and want of ventilation; consecutive pneumonia, as it is then termed, often arises in the course of typhoid, of typhus, and eruptive fevers. In many cases the patient is feverish and unwell for 3 or 4 days before the actual invasion of the disease; this is almost invariably marked by well defined rigor, followed by pain in the side, cough, accelerated breathing, and fever. The pain in the side, commonly felt beneath the nipple, is no guide to the seat of the disease; it is generally caused by accompanying inflammation of the pleura, is lancinating in character, increased by inspiration and by motion of the thorax; according to Grisolle it occurred in 272 out of 301 patients. Accelerated breathing is an invariable symptom, the respirations varying from 30 to 50 in a minute, though they may be as frequent as 80. The pulse does not increase in the same ratio as the respiration; the ordinary relation of 4½ pulsations to a respiration is disturbed, and is reduced to 3, 2, or even less. Dr. Walshe says he has seen this perverted pulse ratio prove the first sign of pneumonia, appearing before crepitation or rusty expectoration. Cough is an almost invariable symptom, occurring commonly at the commencement of the disease; it is not paroxysmal, and is not aggravated at night. In a great majority of cases the cough is accompanied by expectoration, which is pathognomic of the disease. It is tenacious, semi-transparent, little aërated, and of a lemon, orange, or rust color, according to the amount of blood with which it is combined. When free blood occurs in the expectoration, according to Walshe, the pneumonia is complicated by the presence of tubercles. As the disease subsides the expectoration gradually becomes opaque and bronchial. In some cases, instead of being transparent and viscid, the expectoration is diffluent, watery, and of a dark color resembling prune or licorice juice. This is always a serious symptom. The pulse is most commonly frequent, full, and strong; the skin is hot; during the height of the disease the face is often deeply flushed, sometimes almost livid. The pathognomonic physical sign of the first stage of pneumonia is the crepitant rhonchus; this is fine, dry, equal, and heard chiefly at the end of the inspiration. To distinguish it it is often necessary to make the patient cough. In a short time the crepitant rhonchus is replaced by bronchial respiration; the breathing is loud, blowing, and tubular, and when the patient speaks the voice has the diffused resonance to which the term bronchophony is applied. At the limits of the bronchial respiration, while the inflammation is extending, the crepitant rhonchus is still heard. As bronchial respiration replaces fine crepitation, percussion becomes dull over the affected portion of the lung; at the same time the vibratory thrill felt when the patient speaks, by the hand placed upon the chest, becomes more marked. When pneumonia is central and the inflamed part of the organ is separated from the parietes by healthy lung tissue, both percussion and auscultation may give negative results. When the attack of pneumonia results in recovery, as the general symptoms diminish in intensity and the expectoration becomes white or grayish, the bronchial respiration becomes less strongly marked, and over the parts last attacked a coarser and moister crepitation recurs; this is the redux crepitant rhonchus. With the return of the crepitant rhonchus the percussion note becomes clearer, until gradually the lung recovers its former condition. When on the other hand the attack is fatal, the general symptoms, with the exception of pain, persist and are aggravated; the expectoration becomes of a dirty gray color, striated, and finally perhaps wholly purulent; the complexion grows pale, yellowish, and earthy looking; the skin is covered with a viscid sweat, and death is preceded by the tracheal rhonchus. In general the intelligence remains unimpaired to the last. On post-mortem examination the lungs are found in various stages of inflammation, and frequently the three stages commonly recognized are seen in the same patient. In the first stage of inflammation, engorgement, the lung substance is heavier, of a darker color, does not crepitate when pressed between the fingers, and on being cut into gives exit to a frothy, sero-sanguinolent liquid. In the 2d stage, that of red hepatization, the lung is dark-colored, compact, friable, its tissue being easily broken up by the finger; its substance when cut into, or better when torn, presents a multitude of small rounded granulations. In the 3d stage, gray hepatization, while presenting many of the characteristics of the 2d, the lung tissue is of a gray or yellowish color. At first this grayish color presents itself in scattered points, but these gradually coalesce. The lung is still more friable than before, and is easily broken down into a pulp; on being incised a thick fluid of a disagreeable odor, a mixture of blood, pus, and mucus, escapes. In rare instances abscesses are formed in the lungs as a consequence of pneumonia.—The duration of pneumonia is rarely less than 7 or more than 10 days. Very fatal in young infants and in old people, it is attended with but little danger between the ages of 6 and 50, when uncomplicated and occurring in patients of good constitution. When pneumonia is double, when it is complicated with heart disease, with albuminuria, or with delirium tremens, when it occurs in constitutions deteriorated by fatigue, privations, or excess, its gravity is very greatly increased. It sometimes occurs as an epidemic, and is then a severer disease than when it is sporadic.—But a few years ago not many would have been bold enough to question the curative influence of bloodletting in pneumonia, and yet it is now repudiated altogether by many practitioners of the highest authority. It is certain, however, that in strong, healthy, young adults, a single full bleeding will often relieve the breathing, remove the pain, and diminish the force and frequency of the pulse; in other cases, where the pain in the side is severe, it is best to have recourse to cupping glasses. Afterward small doses of tartrate of antimony combined with morphia may be given every 2 or 3 hours. The patient should be kept in bed, the chest should be covered with an oiled silk jacket, and the diet should be bland but nutritious. Where patients are feeble, broken down, or advanced in years, general bloodletting is inadmissible, and even antimony must be used with great caution. A nutritious diet, and the administration of carbonate of ammonia, and frequently of stimulants, form, in such cases, the appropriate treatment.—Chronic pneumonia, except as an attendant upon tubercle or cancer, is an exceedingly rare affection. In it the lung becomes dry, gray, reddish, or black, indurated, and impermeable to air. It may occur as a primary disease, or may follow an attack of acute pneumonia. The patient gradually loses flesh and strength; there is cough with trifling expectoration and no hæmoptysis, and slight but irregular fever. The physical signs are dulness on percussion over the affected part, with feeble, harsh, or bronchial respiration, and increased vocal fremitus. When it affects the upper lobe of the lung, the diagnosis between chronic pneumonia and phthisis must be exceedingly difficult. The disease is generally a fatal one, and the treatment usually consists in supporting the strength of the patient and allaying the symptoms which may arise during its progress.

PO (anc. *Padus* and *Eridanus*), a river of N. Italy, which has its source in two springs about 6,000 feet above the level of the sea, near lat. 44° 40′ N., long. 7° E., on the E. side of Monte Viso, one of the Cottian Alps, and flows into the Adriatic by a delta, the most important branches of which are the Po della Maestra and Po di Primaro, between lat. 44° 51′ and 45° N., and long. 12° 20′ and 12° 30′ E., after a very circuitous but generally E. course of rather more than 450 m. It receives a great number of tributaries both from the Alps on the N. and the Apennines on the S. The most important of the former are the Dora Riparia, Chisone, Sangone, Dora Baltea, Stura, Sesia, Ticino, Olona, Adda, Oglio, and Mincio; and of the latter the Vraita, Tanaro, Scrivia, Staffora, Trebia, Nura, Taro, Parma, Enza, Secchia, and Panaro. About 50 towns of considerable size are situated on its banks or those of its tributaries, and boats can ascend to within 60 m. of its source, but the current is so rapid as to render navigation difficult. Destructive floods are liable to happen at all seasons from heavy rains, and during the summer months from the melting of snow on the mountains; and the flat country through which the lower part of the river flows renders artificial embankments necessary to confine it to its channel. Below Piacenza dikes have been formed, but extensive inundations occasionally happen. The bed of the Po, like that of the Nile, is being continually raised by the deposits made by the river. This rising of the level of the water renders it necessary to make a corresponding increase in the height of the embankments, and the effect of these operations has been that in many places the surface of the river is from 15 to 20 feet higher than the country through which it flows. The breadth of the bed of the Po from the junction of the Ticino to the formation of the delta varies from 400 to 600 yards, and the depth from 12 to 35 feet. The basin of the Po includes an area of about 40,000 sq. m., and comprises the whole of Piedmont and Lombardy, parts of southern or Italian Tyrol, western Venetia, and the Swiss canton of Ticino, a part of the canton of Grisons, the duchies of Parma and Modena, the territories of Bologna, Ferrara, and Ravenna, and a small part of Tuscany. Fish are abundant in both the main stream and its tributaries, the most valuable kinds being salmon, shad, and sturgeon.

POACHING. See GAME LAWS.

POCAHONTAS. I. A central co. of Va., intersected by Greenbrier river; area, 710 sq.

m.; pop. in 1860, 3,958, of whom 252 were slaves. It has an elevated and mountainous surface, being traversed by the Greenbrier range toward the W., and bounded S. E. by a main range of the Alleghanies. A large portion of the land is infertile. The productions in 1850 were 51,949 bushels of Indian corn, 11,806 of wheat, 52,998 of oats, 5,911 tons of hay, 24,422 lbs. of wool, and 76,080 of butter. There were 7 churches, and 200 pupils attending public schools. Value of real estate in 1856, $1,218,147, being an increase of 27 per cent. since 1850. Capital, Huntersville. II. A N. W. co. of Iowa, drained by Lizard and other small rivers; area, 625 sq. m.; pop. in 1860, 103. It produced in 1859 1,265 bushels of Indian corn, 1,125 of potatoes, and 298 tons of hay.

POCAHONTAS, daughter of Powhatan, an Indian chief of Virginia, born about 1595, died in Gravesend, England, in March, 1617. She was early remarkable for the friendship she manifested for the English colonists of Virginia, a striking evidence of which was given when she was about 12 years old. Capt. John Smith having been taken prisoner, it was decided to put him to death. His head was laid upon a stone, and the savages were brandishing their clubs preparatory to dashing out his brains, when Pocahontas threw herself upon the captive's body, and saved his life. When Smith had returned to Jamestown, he sent presents to Pocahontas and her father; and after this the former "with her wild train visited Jamestown as freely as her father's habitation." In 1609 she passed one dark night through the wood to inform Smith of a plot upon the part of her father to destroy him. In 1612 she was living in the territory of the Indian chief Japazaws, having probably gone thither on account of the resentment of her father at her conduct. Capt. Argall bribed Japazaws to betray her into his hands, and having gained possession of her person began to treat with Powhatan for her restitution, but the parties were unable to agree. While on shipboard, however, an attachment sprang up between her and an Englishman named John Rolfe, and the consent of Sir Thomas Dale and of her father having been gained, they were married at Jamestown in April, 1613. A peace of many years' duration between the English and the Indians was the consequence of this union. Before her marriage she had become a Christian, and had been baptized, receiving the name of Rebecca. In 1616 she accompanied Dale on his return to England, where she was an object of great interest to all classes of people, and was presented at court by Lady Delaware. When Smith went to visit her in London, after saluting him she turned away her face and hid it in her hands, and remained in this position for 2 or 3 hours. For some reason she had been taught to believe that he was dead, and there is but little doubt that her husband was a party to the deception. Pocahontas prepared to leave England with regret, but she suddenly died as she was on the point of embarking. She left one son, who was educated by his uncle, a London merchant, and in after life went to Virginia, where he became a person of note and influence. A number of his descendants still exist in that state.

POCOCK, **Edward**, an English divine and orientalist, born in Oxford in Nov. 1604, died there, Sept. 10, 1691. He was graduated at Oxford in 1622, and turning his attention to the study of the oriental languages, prepared an edition in Syriac of the 2d epistle of St. Peter, the 2d and 3d of St. John, and that of St. Jude, parts of the Syriac New Testament which had not previously been edited. Having been ordained priest in 1629, he went out to Aleppo as chaplain of the English merchants in that city, and there remained 5 or 6 years, studying Hebrew, Syriac, Ethiopic, and Arabic. Returning in 1636, he was appointed first incumbent of the Arabic professorship founded by Laud, by whom he had been commissioned, while in the East, to procure ancient coins and manuscripts. He soon went again to the East at the instance of Laud, remained at Constantinople nearly 4 years, and having obtained many valuable manuscripts, came home in 1640 by way of Italy and France, making at Paris the acquaintance of the celebrated Maronite Gabriel Sionita, and of Hugo Grotius. Resuming his lectures and studies at the university, he was presented in 1643 to the rectory of Childrey in Berkshire; and so little display did he make of his learning that he was characterized by one of his parishioners as "a plain honest man, but no Latiner." In 1647, through the influence of Selden, he obtained the restitution of his salary as Arabic professor for the preceding 3 years, which on the execution of Laud had been withheld from him. Charles I. while a prisoner in the isle of Wight in 1648, nominated him to the professorship of Hebrew with a canonry of Christchurch added; but in Nov. 1650, he was ejected from the latter, and was about to be deprived of the former when a petition from the heads of houses and the masters and scholars at Oxford was so favorably received, that he was permitted to enjoy both places. In 1655 an information was laid against him by the commissioners appointed by parliament "for ejecting ignorant, scandalous, insufficient, and negligent ministers;" and probably he would have been removed from his rectorship had it not been for the indignant remonstrances of many of his Oxford friends, especially Dr. Owen. Some time before he had published *Specimen Historiæ Arabum*, consisting of extracts from Abulfaragius in the Arabic with a Latin translation and notes appended; and in 1655 appeared at Oxford his *Porta Mosis*, which were 6 prefatory discourses to the commentaries of Moses Maimonides upon the Mishna. He had a considerable share in the preparation of Walton's polyglot Bible, which appeared in 1657; and in 1658 he published at Oxford, in 2 vols. 4to., his Latin translation of the "Annals" of Eutychius. At the restoration he was made canon of Christchurch, as the grant was originally, and shortly after published an Arabic version of Grotius's tract *De Veritate*, and an Arabic poem of Abu Ismael Tograi with a Latin translation and notes. His great work, however, was the translation of the *Historia Dynastiarum* of Abulfaragius, with the text and notes (2 vols. 4to., Oxford, 1663). He published in 1674 an Arabic version of the church catechism and liturgy; in 1677 his "Commentary upon the Prophecies of Micah and Malachi," in 1685 that on Hosea, and in 1691 that on Joel. At the time of his death he had long enjoyed the reputation of being the first orientalist in Europe.—Pocock's son, Edward, published in 1671, under his father's direction, the philosophical treatise of Ibn Tofayl, with a Latin version and notes, being the same which was afterward translated into English by Ockley. He also translated into Latin the work of Abdallatif on Egypt, but it was not published until 1800. Another son, Thomas, made an English translation of the work of Menasseh ben Israel, *De Termino Vitæ* (12mo., London, 1699).—An edition of Pocock's theological writings appeared at London in 1740 (2 vols. fol.), with an account of his life and writings by Leonard Twells, M.A.

POCOCKE, Richard, an English traveller, a distant relation of the preceding, born in Southampton in 1704, died in Meath in Sept. 1765. He was graduated at Oxford in 1731. In 1737 he began his travels in the East, and after his return in 1742 published his "Observations on Egypt," the first volume of a work under the general title of "A Description of the East and some other Countries." The second volume, entitled "Observations on Palestine, or the Holy Land, Syria, Mesopotamia, Cyprus, and Candia," appeared in 1745. In the same year he was made archdeacon of Dublin, in 1756 bishop of Ossory, and in 1765 bishop of Meath.

PODIEBRAD, George, king of Bohemia, born in 1420, died March 22, 1471. He was the son of Herant of Podiebrad and Kunstat, a Hussite nobleman. The Hussite war, which was agitating Bohemia during his youth, enlisted all his feelings; but while the Bohemian king and German emperor Sigismund lived he acted with the moderate party. After that monarch's death, the Hussites repudiated the election of Albert of Austria, and chose as their ruler Casimir, brother of Ladislas III., king of Poland. Albert, however, succeeded in driving the Hussites and Poles to Tabor, and began the siege of that fortress; but Podiebrad by a successful sally forced him to raise it, and to retreat to Prague. Among the Hussites he now became second only to Henry Ptacek of Lipa, and after the death of that leader in 1444 he succeeded him as regent during the minority of Ladislas, the son of Albert. For a long time he was engaged in conflicts with Meinhard of Neuhaus, the leader of the Catholics, but in 1450 the Calixtines triumphed, and in 1451 Podiebrad was recognized as ruler by the whole country. His authority was confirmed when the deputies of Hungary, Austria, and Bohemia met in Vienna to agree upon a plan for the government of their respective countries, and the guardianship of the young king Ladislas. After the death of that monarch (1457), Podiebrad was elected king of Bohemia, May 7, 1458, and was crowned in 1461; and in this position he maintained himself both against foreign and domestic enemies. No sooner had he ascended the throne than he banished, according to agreement, the Taborites, Picards, Adamites, and all other religious sects not Catholic. The pope, however, annulled the compacts entered into between the Calixtines and the Catholics, and excommunicated Podiebrad in 1463; but through the mediation of the emperor Frederic the contest was settled for a time. But the new pope, Paul II., deposed Podiebrad, and caused a crusade to be preached against him throughout Germany; and on this account the king of Bohemia in 1468 declared war against the emperor, and ravaged Austria as far as the Danube. The emperor now induced Matthias Corvinus, king of Hungary, to take up arms against Podiebrad, and the Catholics of Bohemia were also excited to insurrection. Podiebrad recalled the exiled heretics, suppressed the domestic insurrection, drove back the Hungarians who had invaded his territory, and negotiated an armistice with Matthias, April 14, 1469. The latter, however, soon broke his agreement, and was chosen king of Bohemia by a mock diet held at Olmütz; but Podiebrad succeeded in having Ladislas, eldest son of Casimir IV., king of Poland, of the house of Jagiello, chosen as his successor. The war continued until an armistice was agreed upon, July 22, 1470; and upon his death in the following year he was succeeded by Ladislas, while his two sons, Victorin and Henry, returned to the position of Bohemian nobles.

PODOLIA, formerly a province of Poland, and now a government of Russia, bounded N. by Volhynia, N. E. by Kiev, E. and S. by Cherson, S. W. by Bessarabia, and W. by Austrian Galicia; extreme length 250 m., breadth 140 m.; area, 16,675 sq. m.; pop. in 1856, 1,750,547. Kamieniec, or Kamenetz Podolskoi, the capital, is the only town of importance. An offset of the Carpathian mountains enters Podolia from Galicia and traverses it in a S. E. direction, but in no part exceeds 600 feet above the sea. The surface in other directions is flat, with a general slope to the S. E. The principal rivers are the Dniester and southern Bug; the former constitutes the S. W. boundary, and the latter rises on the N. frontier, and flows S. E. There are no lakes of any considerable size, but small ones are numerous in the western part. The most valuable minerals are saltpetre, limestone, and alabaster. The climate is mild, and the soil particularly fertile. Different kinds of grain, potatoes, hemp, flax, and tobacco are raised in

The early history of the laureateship in England is traditional. The common story is that Edward III. in 1367, emulating the crowning of Petrarch at Rome, granted the office to Chaucer, with a yearly pension of 100 marks and a tierce of Malvoisie wine. The legend probably arose out of an annuity of 20 marks granted by that monarch to his "valet Geoffrey Chaucer," with the controllership of the wool and petty wine revenues for the port of London, the duties of which he was required to perform in person. There is no evidence even that this laborious office was conferred on the ground of poetical merit. Henry Scogan is mentioned by Ben Jonson as the laureate of Henry IV. John Kay was court poet under Edward IV., and Andrew Bernard held the same office under Henry VII. and Henry VIII. John Skelton received from Oxford, and subsequently from Cambridge, the title of poet laureate; and Spenser is spoken of as the laureate of Queen Elizabeth, on the ground of having received a pension of £50 a year when he presented her the first books of the "Faery Queen." The names of Samuel Daniel and Michael Drayton were also associated with the laureateship, although the latter "was one of the poets," says Southey, "to whom the title of laureate was given in that age, not as holding the office, but as a mark of honor to which they were entitled." Up to this time the laureateship had not been established, nor can there be found any certain trace of wine or wages. But the introduction into England from Italy of masques during the reign of Elizabeth rendered necessary the employment of poets, and in 1619 James I., probably to save expense, secured the services of Ben Jonson by granting him by patent an annuity for life of 100 marks. Although not mentioned in the document as the laureate, he was doubtless deemed such. In 1630 the laureateship was made a patent office in the gift of the lord chamberlain, the salary was increased from 100 marks to £100, and a tierce of Canary wine was added, which, however, was commuted in the time of Southey for £27 a year. From that time until the present there has been a regular succession of laureates. The following is a list of those who have held the office, with the dates of their accession and withdrawal:

Ben Jonson.......	1630-1637	Colley Cibber.....	1730-1757
William Davenant.	1638-1668	Wm. Whitehead...	1758-1785
John Dryden......	1670-1689	Thomas Warton...	1785-1790
Thomas Shadwell..	1689-1692	Henry James Pye.	1790-1813
Nahum Tate......	1693-1714	Robert Southey...	1813-1843
Nicholas Rowe....	1714-1718	Wm. Wordsworth.	1843-1850
Lawrence Eusden..	1719-1730	Alfred Tennyson...	1850.

As might be inferred from many of the names in this list, political considerations often controlled the appointment to the office. Such considerations removed Dryden and substituted in his place Shadwell, whose appointment the earl of Dorset vindicated, "not because he was a poet but an honest man." To such an extent was the degradation of the office carried by its connection with unworthy names, that a strong feeling was raised in favor of its abolition. After the derangement of George III. in 1810 the performance of the annual ode was suspended, and subsequently fell completely into disuse. Upon the death of Pye the office was offered to Walter Scott, who declined it, but recommended Southey; and the latter was appointed with the virtual concession, which has since become the rule, that he should write only when and what he chose. Wordsworth wrote nothing in return for the distinction, and Tennyson has written but little.

POETRY (Gr. ποιεω, to make), imaginative composition in metrical or highly fanciful language. In this work the history of poetry is treated in connection with the literature of the several nations of the world, and with the biography of individual poets. See also Bacchanalian Songs, Ballad, Drama, Epic, Elegy, Lyric, and Sonnet.

POGGENDORF, Johann Christian, a German natural philosopher, born in Hamburg, Dec. 29, 1796. Having devoted considerable attention to pharmacy, chemistry, and natural philosophy, he went to Berlin in 1820 for the purpose of prosecuting his studies, and in 1821 published in the *Isis* a treatise "On the Magnetism of the Voltaic Pile," in which were developed for the first time the principles of the application of the multiplicator. In 1824 he was appointed editor of the "Annals of Natural Philosophy and Chemistry," which under his direction became one of the first scientific journals of Germany. In 1834 he became professor of natural philosophy in the university of Berlin, and in 1838 member of the academy of sciences. He was engaged with Liebig in editing a "Dictionary of Chemistry," for which however he did little after the first volume. In 1853 appeared his "Studies for a History of the Exact Sciences," the forerunner of a "Biographical, Bibliographical, and Historical Dictionary of the Exact Sciences," begun in 1858. His scientific investigations have been directed chiefly to electricity and magnetism.

POINDEXTER, George, an American politician, born in Louisa co., Va., died in Jackson, Miss., Sept. 5, 1853. He began his career as a lawyer in Milton, Va., but in 1802 removed to Mississippi territory, where soon after he was commissioned by Gov. Claiborne as attorney-general, which appointment he held when Aaron Burr was arrested by the territorial authorities. He was involved in many quarrels, personal and political, and from one of these a duel resulted in which he killed Abijah Hunt, then the most extensive merchant of the South-West. Bitter and prolonged controversies grew out of this affair, and Mr. Poindexter and his seconds were charged with gross unfairness, but the charges were never satisfactorily sustained. In 1807 he was elected delegate to congress, where he soon became distinguished as a debater. He remained in congress until

1816, when, against the remonstrance of a majority of the bar of Mississippi, he received the appointment of U. S. judge for that district. It was an office that demanded the highest grade of professional attainment, owing to the conflicting tenures and extensive litigation arising from ill defined and fraudulent grants of land made by the Spanish and British authorities, formerly proprietors of the public domain; and, notwithstanding the previous enmity to him and doubts of his integrity, it is acknowledged that Judge Poindexter discharged the duties of his office with eminent ability and impartiality. After the admission of Mississippi as a state in 1817 he was elected its first representative in congress. In the great debate in the house in the beginning of 1819 on the conduct of Gen. Jackson in the Seminole war, the speech of Poindexter was regarded as the ablest delivered, and to it more than to any other Jackson owed his triumphant acquittal. After the close of his term he was elected governor of Mississippi, notwithstanding the most violent assaults upon his character, including a false charge of gross cowardice in the battle of New Orleans, where he served as volunteer aid to Major-Gen. Carroll. In 1831 he was chosen a member of the U. S. senate, where, from being a personal and political friend of Jackson, he gradually took his place in the ranks of the opposition. He occupied, as he contended, a middle ground between the parties of Clay and Calhoun; but there was little practical difference between Calhoun and himself. He became exceedingly obnoxious to Gen. Jackson, and was suspected by him of complicity in the attempt made upon his life at the capitol. In 1835, disgusted at the conduct of his own state, and influenced also by the prospect of political promotion that had been held out to him in Kentucky, he removed to Louisville, but his expectations were disappointed. He was commissioned by President Tyler to investigate certain frauds in the New York custom house, and finally resumed his citizenship in Mississippi, and his connection with his old political friends.

POINSETT, a N. E. co. of Ark., bordered E. by the St. Francis river and Lake St. Francis, and drained by the L'Anguille and several other rivers; area, 1,850 sq. m.; pop. in 1860, 3,621, of whom 1,096 were slaves. It has a level surface and fertile soil. The productions in 1850 were 164,099 bushels of Indian corn, 2,715 of wheat, 8,800 of oats, and 1,017 bales of cotton. In 1850 there were 5 churches, and 220 pupils in public schools. Capital, Bolivar.

POINSETT, Joel Roberts, an American statesman, of Huguenot descent, born in Charleston, S. C., March 2, 1779, died in Statesburg, S. C., in Dec. 1851. His education was completed in Europe at a private school near London, and he studied medicine and the natural sciences at the university of Edinburgh, after which he entered the military academy at Woolwich. In 1800 he returned to Charleston and commenced the study of the law, but from ill health he returned in 1801 to Europe, and remained a number of years, visiting nearly the whole of the continent. Returning to the United States in 1809, he was sent by President Madison to South America to ascertain the political condition of the country. He visited Rio Janeiro and Buenos Ayres, and thence crossed the continent to Chili, establishing friendly relations in behalf of the U. S. government. On his return to South Carolina he became a member of the legislature, and in 1821 was elected to congress from the Charleston district. In the succeeding year he visited Mexico in a semi-diplomatic capacity to report upon the condition of the country and the policy of opening diplomatic relations with the emperor, Iturbide. He was twice reëlected to congress, and upon the accession of Mr. Adams to the presidency received the appointment of minister to Mexico. The distracted state of the country at that time rendered it difficult for a diplomatic agent to avoid committing himself in favor of one or another of the various factions into which the people were divided, and Mr. Poinsett was accused by the aristocracy and the church party of interfering against them. He justified his course in a pamphlet published after his return. He held the office at considerable personal risk for 18 months, negotiating during that period a treaty of limits and one of commerce, and was recalled by President Jackson. Returning to Charleston in the midst of the nullification excitement, he attached himself to the union party, of which he became the leader, and which, though asserting the state rights doctrines, held that nullification was disunion, and that the passage by congress of a protective tariff did not justify so extreme a measure. After the defeat of the union party, for whose cause Mr. Poinsett labored with great earnestness, he retired for several years from public life. In 1837 he was appointed by President Van Buren secretary of war, in which capacity he urged the maintenance of a portion of the militia on a war footing—a measure which was denounced as an attempt to organize a standing army. During his residence in Washington he took much interest in the welfare of the city, and endowed the national institute with a valuable museum, beside distributing large collections of objects of antiquarian interest among the public institutions of New York, Philadelphia, Charleston, and other places. The last 10 years of his life were passed in retirement. On his return from Mexico he published a volume of "Notes" on that country (Philadelphia and London, 1824), and he was an occasional contributor to the "Southern Quarterly Review," the "Democratic Review," and other periodicals. He left a large body of correspondence, notes, and memorials relating to the greater part of his career, but which have not yet been edited.

POINT COMFORT. See Old Point Comfort.

POINT DE GALLE, a fortified town in Ceylon, situated upon a rocky promontory at the S. W. extremity of the island, 72 m. S. S. E. from Colombo, 572 m. from Madras, 2,150 m. from Aden, and 1,213 from Penang; pop. about 5,000. It is the coaling depot and port for transshipping passengers and goods from one line to another for the steamers that ply between Calcutta, Australia, and Suez, Bombay, Penang, Singapore, and China, with branches to the Dutch and Spanish possessions in the Indian archipelago. The native artisans are celebrated for their skill in making gold and silver ornaments, workboxes, &c.

POINTE COUPÉE, a S. E. parish of La., bordered E. by the Mississippi river and W. by the Atchafalaya; area, 576 sq. m.; pop. in 1860, 17,720, of whom 12,903 were slaves. It has a low and level surface, subject to overflow by the river, and a fertile soil. The productions in 1850 were 199,790 bushels of Indian corn, 43,643 of sweet potatoes, 8,560 hhds. of sugar, 821,546 galls. of molasses, and 1,622 bales of cotton. There were 2 churches, 1 newspaper office, and 160 pupils attending public schools. Capital, Pointe Coupée.

POINTER (*canis avicularis*), a well known sporting dog belonging to the race of hounds, which it resembles in general aspect, character, and colors. Though frequently called Spanish, and probably introduced by the Phœnicians into western Europe through Spain, the breed is generally believed to have originated in the East. Their habit of standing fixed and pointing to game is the result of a long course of severe training; and, from the succession of generations educated to this purpose, the faculty has become innate to such a degree that young dogs of the pure breed point with scarcely any instruction; good dogs have been known to stand pointing for an hour at a time. When shooting supplanted hawking and coursing, in the latter part of the 17th century, the pointer and other trained dogs took the place of the more powerful, fiercer, and swifter hounds. The hair of the pointer is smooth, sometimes marked like the fox hound, but generally with more spreading dark colors; and some of the best breed are entirely black. The thorough-bred Spanish pointer has the nostrils separated by a deep groove, and their wings dilated and very sensitive. The position of the pointer, with his head to the game and one fore foot raised, is familiar to all; a good dog will not only stand thus at the scent of his game, but will instantly back if he sees another dog point, in company with him.

POISON, any substance which, introduced in small quantities into the animal economy, seriously disturbs or destroys the vital functions. Under this head are obviously included a vast number of bodies belonging to the mineral, vegetable, and animal kingdoms, some solid, others fluid, and others gaseous, and deleterious vapors and miasmata imperceptible to the senses. The science which treats of these is designated toxicology. Until of late years the true nature and effects of poisons were little understood, although poisonous mixtures were much used among the ancient Greeks and Romans as a means of destroying life. What the preparations were of this character which they employed we have no means of ascertaining, and it is altogether uncertain whether the deadly hemlock was a plant we can now identify. (See Hemlock.) Among the multitude of substances that rank as poisons are many, some possessing the most active qualities, which are also useful drugs, and which, administered in suitable quantities, are recognized among medicines in universal employment and of the most beneficial character. Such are the preparations of opium, tobacco, the salts of mercury, and even arsenic. The active ingredients of several articles used for food are also in a concentrated state virulent poisons, as caffeine, &c.; and various other articles of food, as shell fish and eggs, sometimes affect some persons as poisons.—The action of poisons upon the human system is variously exhibited. Some merely corrode and destroy the textures they come in contact with, and the sympathetic influence of such injuries may reach the vital functions. Others produce local inflammations, and some act upon the nerves of the parts they reach. Some poisons, most virulent when introduced into the circulation, as the venom of snakes, may be swallowed with impunity. But most poisons, however they may be introduced into the system, whether through the cuticle, by respiration, or by the alimentary canal, are rapidly disseminated, probably through the blood, and their influence is felt in those organs which are peculiarly sensitive to their action. Many soon reach the brain and produce a fatal coma. Arsenic attacks the stomach and intestines. As remarked by Dr. Christison: "The spine is affected by nux vomica, the kidneys and bladder by cantharides, the lungs by tartar emetic, the heart by oxalic acid, the liver by manganese, the salivary organs by mercury, and many of the glands by iodine." Some of them, moreover, as arsenic and mercury, affect at the same time different organs. The quantity of many of these substances required to produce poisonous effects is extremely minute; in the case of poisonous reptiles and insects, and the virulent fluids of dead bodies after certain diseases, it is quite insignificant. Strychnia and prussic acid may either of them prove fatal in a few minutes to a strong man when taken in the dose of a grain. But various circumstances greatly modify the action of the poisons. Some persons are much more susceptible to their influence than others. Many are almost sure to be affected by passing through a wood where certain poisonous plants grow, while others may even handle the plants themselves with impunity. The classification of poisons into three great divisions, founded on the symptoms they produce, is noticed in the article Medical Jurisprudence, vol. xi. p. 849; the treatment adapted to correct the effects of the several poisons in the article Antidotes; and the characters of the most important poisonous substances are given under their respective names.—In the case of the bites of poisonous snakes, several effective modes of treatment are reported of late as having been introduced in the western states. Popular remedies have been large draughts of whiskey, and chewing and swallowing tobacco, and also applying it to the wound. The alcohol does not apparently act as an antidote, but it stimulates the nervous system, keeping it above the depressing influence of the poison till this is overcome by the natural curative action. The tincture of iodine applied externally has proved a very remarkable remedial agent. The method of using it in recent cases or within 15 hours after the bite is to inject the cellular tissue in and about the wound with the tincture by means of a sharp-pointed silver syringe, and apply the same upon the swollen parts and 2 or 3 inches beyond them. If the case is further advanced, wine or brandy is given in addition, with iodide of potassium and chloride of potassium largely diluted in water and followed by tonics. Dr. B. J. D. Irwin of the U. S. army reports the discovery of an antidote to the poison of the rattlesnake, in common use with universal success by the Mexicans and Indians. This is a plant known among them as the *golondrinera*, and which proved, when examined by Prof. John Torrey of New York, to be a species of *euphorbia*, several of which, as the *E. capitata*, *E. corollata*, *E. palustris*, and *E. villosa*, are also celebrated as specifics against the bites of poisonous animals. The golondrinera is the *E. prostrata*, a plant of frail delicate appearance, somewhat like the gold-thread, and having long reddish stems that spread and interlace with each other. Its flowers, which appear from April to November, are very small, white with dark purple throat. They are axillary, and have 4 petals and 4 sepals. All parts of the plant, even the large root, contain an abundance of milky juice, in which its medicinal properties reside. It grows plentifully in dry gravelly and sandy places, by roadsides and in farm yards. Its juice is extracted by bruising portions of it in a mortar. A considerable portion of water is added, and several ounces of the mixture are administered to one bitten by any of the venomous snakes, scorpions, tarantulas, or other poisonous reptiles, which abound in Arizona and Sonora. The remedy is said never to fail of effecting a cure, and its administration is attended with no danger. Its action is that of an emetic and cathartic.

POISON IVY, or **Poison Oak**, a poisonous shrub or vine common throughout the United States, and called sometimes by one and sometimes by the other name. It belongs to the natural order *anacardiaceæ*, and was named by Linnæus *rhus toxicodendron*, or when climbing trees, *R. radicans*. It ascends trees and rocks, attaching itself to them by multitudes of strong root-like fibres that project from the stem, and maintain a strong hold upon the bodies they reach. The leaflets grow 3 together at the end of long petioles; they are rhombic ovate in form, mostly pointed, smooth and shining on both sides, and rather downy beneath. A yellowish milky juice exudes from a broken leaf or stem, and becomes by exposure of a permanent deep black color, making a most perfect indelible ink for linen; this is soluble in boiling ether. If when obtained by pounding the leaves in large quantities the juice retained this property, it might prove to be a valuable dye; but such is found not to be the case. The juice and effluvium from the plant exert a poisonous influence to which many persons are extremely sensitive, while others are not at all affected even by chewing the plant. Though the poisoning rarely proves fatal, the eruptions and swellings produced are attended with much pain and distress, which however usually yield to the ordinary treatment by purging and external use of sugar of lead, &c. The variety common in California, there known as the poison oak, sometimes attains a diameter of stem of 6 inches. It appears to be much more virulent in its action than the poison ivy of the East, and cutaneous diseases resembling salt rheum are said to frequently follow its attacks and resist the common remedies. They are, however, cured by what appears to be an infallible antidote to the poison, a decoction of a plant called the *grindelia* (*G. hirsutula* or *G. robusta*), a perennial shrub of the natural order *compositæ*. The plant grows from 1 to 3 feet high, and bears from June to October heads of small yellow flowers like sunflowers. The buds and other parts of the shrub contain a white and sticky resinous matter in which the remedial virtue chiefly resides. The same application is found alike beneficial for many cutaneous diseases. The leaves of the poison ivy have themselves been used as a medicine for the same diseases, being administered internally in doses of a grain each several times a day. A tincture of the plant is also administered internally by the homœopathists as a remedy for various eruptive diseases, and for some paralytic affections.

POISSON, Siméon Denis, a French geometer, born in Pithiviers, Loiret, June 21, 1781, died in Paris, April 25, 1840. He was educated at the polytechnic school, where he became a tutor and professor. In 1809 he was made a professor in the faculty of sciences, and in 1811 in the normal school. His most important production is the *Traité de mécanique* (2 vols. 8vo., 2d ed., 1833). His last work, *Théorie du calcul des probabilités*, appeared in 1838.

POITIERS, or Poictiers (anc. *Lemonum* or *Limonum*, afterward *Pictavi*), a town of France, capital of the department of Vienne, 211 m. S.

S. W. from Paris; pop. in 1856, 26,233. It is situated on a rounded eminence on the left bank of the river Clain, and at the mouth of the Boivre. These two rivers anciently formed a natural fosse without the ramparts of the town and entirely surrounding it, except at a point in the S. W. where was an isthmus defended by a strong wall and an artificial ditch. This space is now converted into a promenade. The town is enclosed by old turreted walls, pierced by 6 gates, 4 of which open on bridges over the Clain. Coarse woollen cloths, blankets, hosiery, lace, &c., are manufactured.—The ancient Lemonum was the chief city of the Celtic Pictones. It was pillaged by the Vandals in A. D. 410, and afterward fell into the hands of the Visigoths, who were driven from it by the Franks. Near it the Visigoths under Alaric were decisively beaten by Clovis in 507, and in 732 Abderrahman and his Saracens were defeated a few miles N. E. of this town by Charles Martel. By the marriage of Eleanor of Guienne to Henry Plantagenet, who became king of England, Poitiers came into the hands of that prince, and was held by the English until 1204, when it was wrested from them by Philip Augustus. On Sept. 19, 1356, a few miles from the city, was fought the famous battle of Poitiers, in which John II. of France, with an army variously stated to be 50,000 and 80,000 strong, was defeated by Edward the Black Prince at the head of 8,000 English and Gascon soldiers. The English were posted in such a manner that they could only be approached through a narrow lane, in which 4 men could scarcely ride abreast, and which was covered upon both sides by very heavy hedges. In the hedges were the English archers, and at the head of the lane in broken ground and among vines were the men-at-arms. The cavalry or knights were held in reserve. Upon this strong position the French, sure of an easy victory, threw themselves with great impetuosity. The first volley from the archers put them into a confusion from which they did not recover. Their charge upon the men-at-arms entirely failed, and being charged in turn and already in great disorder they were completely routed, and King John was captured. Poitiers again reverted to France in 1372 by the voluntary surrender of the townsmen to Charles V. While the English were in possession of the larger part of France, Charles VII. held his court and parliament at Poitiers for 14 years, and during that time great additions were made to the town. During the war of the league it was taken from the Huguenots by the Catholics, and Admiral Coligni made an unsuccessful attempt to retake it in 1569.

POITIERS, Diana of. See Diana.

POITOU, an ancient province in the W. of France, bounded N. by Brittany, Anjou, and Touraine, E. by Berry, Marche, and Limousin, S. by Angoumois, Saintonge, and Aunis, and W. by the bay of Biscay. Previous to the conquest of Gaul by Cæsar, it was inhabited by the Pictavi or Pictones; it afterward formed a part of the province of Aquitania, was conquered by the Visigoths in the beginning of the 5th century, fell into the hands of Clovis, king of the Franks, in 507, and under his Merovingian successors was held by the dukes of Aquitania. During the reign of Pepin the Short it became part of the Carlovingian empire, and received counts of its own. It passed into the hands of the family of Plantagenet by the marriage of Henry II. of England with Eleanor of Poitou and Aquitaine, was taken from John Lackland in 1204 by Philip Augustus, and was recaptured by the English after the battle of Poitiers in 1356, remaining in their hands until 1369, when Charles V. again subjected it. Before the revolution of 1789 it was divided into Upper and Lower Poitou. Before the execution of Louis XVI. the Poitevins rose in insurrection against the convention, and under the name of Vendeans and the leadership of their lords waged a terrible war. They were partly subdued by Gen. Hoche in 1795, but remained royalists at heart. Attempts to renew civil war took place in 1814 on the fall of Napoleon, and after that of Charles X. in 1830 and 1832, but failed. Poitou is now divided into the departments of Deux-Sèvres, Vienne, and Vendée.

POKE (*phytolacca decandra*), a common plant, the typical genus of the natural order *phytolaccaceæ*, with a stout, herbaceous, smooth stem, growing from 6 to 9 feet high; large, spindle-shaped, branching, and perennial roots; scattered, petiolate, ovate oblong leaves, smooth on both sides, ribbed beneath, entire and acute; flowers in racemes, the sepals white and membranous on the margin; stamens 10, with white, roundish, 2-lobed anthers; ovary round with 10 short recurved styles, which uniting form a celled berry, each cell containing a vertical seed. It is a native of North America, and has become naturalized in some of the southern parts of Europe. Other species are indigenous to America, Africa, and India, both within and without the tropics. The common poke delights in rich soils, and particularly thrives on newly cleared and burnt woodlands, where it assumes the habit of a strong and luxuriant weed. Even after its foliage has fallen, its racemes of shining black berries, contrasting with its bright crimson stems and branches, render it conspicuous. These berries contain an abundance of deep purple juice; and tinctures prepared of it have been considered a popular remedy for chronic rheumatism. The root is a violent emetic, and the leaves are extremely acrid, yet the young shoots just springing from the ground are used as a substitute for asparagus. Employed externally as a local stimulant, either in the form of extract or in ointment, the plant has been found efficacious in itch and scald head. Some repute has been given to poke in treatment of cancer, but it is presumable that some milder disease had been mistaken for it. The several names of cocum, pocan, poke, pokeweed, pigeon berry, mechoacan, and garget have been applied to the same species of *phytolacca;* and the

American hellebore (*veratrum viride*, Aiton) is likewise called Indian poke or pokeroot (see HELLEBORE), a far more valuable plant, and related to the European species, which is in high repute. The berries of the common poke are eaten by birds. Their juice has been used to give color to wines, but the practice is discountenanced as injurious. Some value is likewise attached to its root in veterinary medicine.

POLA, a fortified city of Istria in Austria, on the bay of Porto delle Rose, 15 m. S. S. E. from Trieste; pop. 11,000. It is surrounded by Venetian walls of the 15th century, has a cathedral, a Greek church, and 3 convents, and one of the best harbors in Europe. A colony was established at Pola by Augustus, when it was called Pietas Julia; and subsequently it became so flourishing that in the reign of Severus it numbered 30,000 inhabitants. Some of its ruins have been singularly well preserved. Of these the most remarkable are the amphitheatre, 436 feet in length by 346 in breadth, two temples, one of which was a favorite study of the Italian architects, triumphal arches, and portions of the ancient walls.

POLAND (Pol. *Polska*), KINGDOM OF, the westernmost province of Russia in Europe, situated between lat. 50° 4′ and 55° 6′ N., and long. 17° 30′ and 24° 20′ E.; area about 49,539 sq. m.; pop. in 1857, 4,789,379. It is bounded N. E. and E. by the Russian provinces of Lithuania (the governments of Kovno, Wilna, and Grodno) and Volhynia, S. by Austrian Galicia, and W. and N. W. by the Prussian provinces of Silesia, Posen, and West and East Prussia. All these surrounding provinces, as well as numerous others, were formerly parts of the once independent and powerful state of Poland, of which the present nominal kingdom is thus but a fragment. This country consists of a quadrangular territory, from the N. E. corner of which a long and narrow tract, bounded by Lithuania and E. Prussia, stretches northward. The average breadth of the quadrangle from E. to W. as well as its length from N. to S. is about 200 m. By far the greater part of the country is a plain, sinking gently toward the Baltic; only the southern regions are hilly or slightly mountainous, being traversed by the northernmost offshoots of the Carpathians. The Vistula, which flows from that mountain range to the Baltic, enters Poland a little below Cracow, running N. E. along the southern or Galician frontier as far as the mouth of the San, sweeps in a northerly and then northwesterly direction through the middle of the kingdom, and leaves it a little above the Prussian fortress of Thorn. On the right it receives the Wieprz, which rises in the S. E. corner of the country, and the Bug, which rises in Galicia and flows along the E. or Russian frontier; on the left the Nida, the Pilica, which rises in the S. W. corner, and the Bzura. The Narew, which rises in the Russian government of Grodno and receives the Bobr, is an affluent of the Bug from the right, joining it near its mouth. The Niemen, which has its source in the government of Minsk, having traversed Lithuania, reaches Poland near the town of Grodno and flows along the Lithuanian frontier toward the Baltic. The Warta, the source of which is near that of the Pilica, and its affluent the Prosna, which partly separates Poland from Silesia and Posen, are tributaries of the Oder. Most of these rivers are navigable, and form channels for the exportation of produce through the Prussian towns of Dantzic, Stettin, and Tilsit, to the Baltic. There are lakes in the northern part near the Prussian boundary, but none of much size. The climate is healthy but severe, the summer being very hot and the winter very long and exceedingly cold. In the former season, especially when the S. E. winds blow from the steppes of Russia, the thermometer sometimes rises above 90° F., and in the latter it more frequently descends to 15° below zero. The rivers are sometimes ice-bound and the fields covered with snow for 4 or 5 months continuously. The soil is mostly a fertile sandy loam; but there are numerous unproductive tracts covered with sand, heath, or swamps. Rich pastures and vast forests abound. The region between the upper Bug and Vistula is the most fertile, that between the Vistula and the Pilica the most varied and picturesque. The principal productions are wheat, rye, barley, oats, and buckwheat; various leguminous plants; apples, excellent cherries, and other fruit; many kinds of berries, especially strawberries, which are equally delicious and abundant; pine, fir, birch, oak, ash, hazel, lime, and other forest trees; silver, iron, copper, lead, and zinc; cattle, hogs, bees in great swarms, poultry, sheep, and horses, some breeds of the last two being among the best in eastern Europe. Of wild animals the most common are the deer, fox, marten, polecat, weasel, and wolf, the last of which in very severe winters frequently infests the rural districts; among the singing birds are the skylark and the nightingale; the principal fish is the pike.—The bulk of the population consists of Poles, of whom the higher classes are generally well formed, vivacious, warlike, hospitable, and patriotic, but often rash and violent; the women are graceful and spirited, and the peasants sturdy, good-natured, but slavish. The Jews, who form ⅛ of the population, and are allowed to live only in separate town quarters, are mostly poor, careless in dress, speech, and manners, but benevolent, religious, and intellectual. The Germans, who live chiefly in manufacturing towns and in separate agricultural settlements, are distinguished above all the other inhabitants by industry, economy, and cleanliness, but are little liked in other respects. Russians (except the garrisons) and gypsies are not numerous. The Poles almost all belong to the Roman Catholic church; the Germans are mostly Lutherans; the Russians have churches of the Greek rite. The main resources of the country are agriculture and mining. Commerce and the trades are to a great extent in the hands of the Jews, and manufactures in those of the Germans. Woollen cloth, cotton goods, flannel, merinoes, shawls, hosiery, leather, paper, glass, beet root sugar, beer, spirits, iron and zinc, musical instruments, clocks and watches, and carriages are among the principal manufactures, some of which are exported to the various provinces of Russia. Grains, seeds, oil, honey, wool, metals, and timber are exported to the Baltic ports, mostly down the Vistula to Dantzic. A strictly guarded customs line protects home manufactures against foreign competition. A railroad, running across the country in a N. E. and S. W. direction, connects the capital, Warsaw, with the Russian, Austrian, and Prussian provinces. Some of the other important towns are: Sandomir, Pulawy, the fortress New Iwangorod, Praga, a suburb of Warsaw, the fortress New Georgiewsk or Modlin, and Plock, on the Vistula; Czenstochowa, Sieradz, Kolo, and Konin on the Warta; Kalisz on the Prosna; Piotrkow, Lodz, and Rawa, between the Warta and the Pilica; Lowicz on the Bzura; Kielce, Opatow, Konskie, and Radom, between the Pilica and Vistula; Lublin, Lenczna, and the fortress Zamosc, near the Wieprz; Wlodawa and Nur on the Bug; Siedlce S. of it; Lomza, Ostrolenka, and Pultusk on the Narew; Suwalki and Kalwarya in the N. E. projection. The last division of the country is into 5 governments, viz., of Warsaw, Radom, Lublin, Plock, and Augustowo (capital Suwalki), which has superseded a former one into 6 palatinates, viz., of Masovia (capital Warsaw), Kalisz, Cracow (capital Kielce), Sandomir, Podlachia (capital Siedlce), and Lublin. The present governor is Prince Michael Gortchakoff.—The Poles form one of the principal branches of the Slavic family of nations. Their ancestors are believed by the best historians to have occupied the same regions during or soon after the time of the great migration of nations. A few centuries later they appear under the name of Polans between the Oder and Vistula, of Lenczycans E. of the Warta, of Masovians between the Vistula and the Narew, and of Kujavians, Kassubs, and Pomeranians on or near the lower Vistula, being surrounded by kindred tribes, the Obotrits, Wends, Sorabians, Lusatians, Silesians, Bohemians, Moravians, and White and Red Croats, on the W. and S., and by the Prussians, Lithuanians, and others on the E. The Polans, probably so named as inhabitants of the plain (Pol. *pole*, field, plain), formed the most conspicuous group, and eventually gave their name to the whole nation. Their leader or prince Lech, the founder of the city of Gnesen (about A. D. 550), is the first among the heroes of the earliest, that is, legendary Polish history. But as Lach is still used for Pole among the Russians, the name of the fabulous brother of Czech (Bohemian) and Rus (Russia) probably belonged to the people. Equally fabulous are, among others, Krakus, the founder of Cracow; his daughter Wanda, who is said to have defeated in battle a German suitor, Rytygier, whom her patriotism did not allow her to marry, and then to have drowned herself in the Vistula; and the tyrant Popiel, said to have been devoured by mice in his castle in the middle of Lake Goplo. The election of Piast, a pious and benevolent peasant of Kruszwica, as king, is also regarded as mythic, his son Ziemowit being considered the first historical ruler of Poland (860). Little, however, is known of him, or of his successors before Miecislas I. (962-992), who having married Dombrowka, a Bohemian princess, was induced by her to convert his people to Christianity. He divided his dominions among his sons, but Boleslas, the eldest of them, surnamed the Brave or the Great, made himself master of the whole inheritance, extending it by conquests even beyond the Oder, the Carpathians, and the Dniester. He was acknowledged as an independent monarch by the emperor Otho III., who came to Poland to visit the tomb of St. Adalbert at Gnesen; but he afterward carried on long wars against Otho's successor Henry II., with whom he finally concluded a peace at Bautzen (1018). Dissensions between the successors of Vladimir, grand prince of Kiev, called him to Russia, and he entered that capital in triumph, striking its gold-covered principal gate with a sword received from Otho, which was afterward known among the insignia of the Polish crown under the name of *szczerbiec* (notched). He was no less successful in peace, promoting commerce, a strict administration of justice, and the spread of the new religion, and strengthening the internal defences of the country. This was, however, still in a comparatively rude condition. The principal places were little more than small towns; most of the inhabitants were agriculturists bound to do military service; those who were able to equip a horse were regarded as nobles; prisoners of war were held as serfs; and the government was entirely autocratic. Boleslas was fond of splendor, sports, and military displays, and shortly before his death (1025) had himself crowned as king by his bishops. The reign of his son Miecislas II. was short. His widow Rixa, a granddaughter of the emperor Otho II., reigned for some time badly in the name of her son Casimir, and finally fled with the treasure and the royal insignia to Germany. Casimir followed her, and a period of anarchy ensued. The national heathenism prevailed over the imported worship; the Christian priests were murdered, and their churches destroyed. Russians and Bohemians, grasping the opportunity to take revenge for late defeats, invaded the country. Casimir, who had lived for years the life of a monk, was now recalled (1040), and by the restoration of peace, order, and Christianity, gained the surname of "the Restorer." His son Boleslas II., or the Bold (1058-'81), was warlike, like the first of that name, but without his ability as a ruler. He triumphed over the Bohemians, decided by his intervention the disputes about the Hungarian throne, and on a similar expedition to Russia occupied Kiev. This city, however, proved a Capua to his warriors; the war was protracted for years, and lawlessness and profligacy prevailed in the meanwhile in Poland. On his return he committed acts of tyranny, and even stained his hands with the blood of St. Stanislas, bishop of Cracow, who had reprimanded him. This roused the people against him, and he died in exile. His brother Ladislas (Wladyslaw) Herman (1081–1102), weak-minded and sluggish, resigned the regal title, being satisfied with that of duke, and intrusted all affairs of state to a favorite, Sieciech, whom he raised to the dignity of palatine (*wojewoda*), and whose sway caused general discontent. His two sons finally compelled him to banish the favorite, and Ladislas Herman died soon afterward. His son Boleslas III., the Crooked Mouth (1102–'39), warred with success against the Prussians, conquered Pomerania, converting its inhabitants to Christianity, and defended Silesia against the emperor Henry V.; but, no less passionate than brave, he took a bloody revenge on his half brother Zbigniew for repeated provocations, and died broken-hearted after having been worsted by the Hungarians, Bohemians, and Russians. By his will he divided his dominions among his 4 eldest sons, the youngest, Casimir, receiving no share. Henry received Sandomir, Mieczislas III. (the Old) Great Poland (or Poland proper) with Posen, Boleslas IV. (the Curly-haired) Masovia and Kujavia, and Ladislas II. Pomerania, Silesia, Sieradz, Lenczyca, and Cracow, with the guardianship of his brothers and the title of monarch. But the harmony among the family was of short duration. Ladislas, incited by his German wife, tried to dispossess his brothers, and was deposed. Boleslas was elected monarch in his stead, but after a war against Frederic Barbarossa, who intervened in favor of the eldest line, finally ceded Silesia to the sons of Ladislas, and this province eventually became severed from Poland and Germanized. Mieczislas, who succeeded Boleslas as monarch, shared the fate of the eldest brother (1177), and the crown devolved upon the youngest, Casimir II., surnamed the Just, who had succeeded Henry in Sandomir, and had subsequently also inherited Masovia and Kujavia. He was successful both in peace and war. Important reforms took place during his reign in the administration of the country. An assembly of bishops convoked at Lenczyca in 1180 established the rights of the peasants and the clergy. A senate was formed consisting chiefly of bishops, palatines, and castellans, or governors of the fortified castles. Thus the monarchy became limited by the introduction of a kind of oligarchy, which by subsequent changes was developed into a powerful aristocracy. This was in part a natural consequence of the division of the country, which brought about the appointment of numerous ducal palatines and other officers, chosen from among the nobles. The interests of the lower classes, too, were after the death of the virtuous Casimir more and more disregarded; domains and single estates were granted as presents or rewards to favorites or public officers, with the right of jurisdiction over the peasantry; the obligations of the latter were gradually extended, while the higher nobles were exempted from all public burdens. An attempt of Mieczislas the Old to recover the crown after the death of Casimir failed. The son of the former, Ladislas, was also set up as a rival to that of the latter, Lesco (Leszek) I., the White, but generously resigned (1207). Thus the youngest line of the house of Boleslas Crooked Mouth remained in possession of power. Lesco himself took the provinces of Cracow, Sandomir, and Pomerania; his brother Conrad received Masovia, Kujavia, Sieradz, and Lenczyca. Lesco, a worthy son of Casimir the Just, repeatedly interfered in the affairs of the distracted Red Russian principality of Halicz (Galicia), protecting the house of his former enemy Prince Roman against native factions as well as against the Hungarians. He then turned his attention to the affairs of his own province, Pomerania, in a part of which Sventopelk, a native governor, who had delivered the coast land of the Baltic from the Danes, strove to assume absolute power. Lesco tried to bring about a peaceful settlement, but was treacherously murdered by the Pomeranian. The province, a conquest of Boleslas III., was lost. Conrad, too, who was as rash and cruel as his brother was mild, was unable to cope with his heathen Prussian neighbors. He called to his assistance the Teutonic knights, who were not satisfied with the conversion of the half savage people, but made conquest and power their principal object, carried their arms into Lithuania and Podlachia, and soon became terrible enemies of Poland. Boleslas V. the Bashful (1227–'79), who succeeded his father under the guardianship of his uncle, and grew up to become "an unjust judge, peace-loving knight, and careless ruler," was not the man to restore the power of the state. This was almost annihilated by the great invasion of the Mongol Tartars. Boleslas escaped beyond the Carpathians, whence he continued his flight together with King Béla of Hungary; the people sought refuge in the vast forests or behind the walls of the scanty fortresses. The Mongols burned Cracow, and carried death and devastation even beyond the Oder. Duke Henry the Pious of Silesia fell with his knights on the great battle field of Wahlstatt near Liegnitz in 1241, but the invaders now commenced their retreat, pillaging, burning, and carrying off men and cattle. The decay of the country was general and gradual. The heirs of Conrad subdivided his possessions. Various western districts were pledged for loans or ceded to neighboring German princes, especially to the margraves of Brandenburg, and the Bohemians occupied parts of southern Silesia. The numerous German settlers in the towns, though useful for their industry, extended the influence of their native country by the spread of their language and the introduction of German customs and even laws, especially those regulating commerce and trade, and almost denationalized parts of their adopted land. German warriors and adventurers flocked to the shores of the Baltic, where the Teutonic knights, pressed by the Prussians, Lithuanians, and Sventopelk of Pomerania, allied themselves with the knights sword-bearers of Livonia for common crusading wars on the confines of Poland. The Jews, too, who in the time of the crusades were driven by persecution from Germany, retained in Poland the language which they had adopted on the banks of the Rhine and Danube. Tartars, Red Russians, and even the Lithuanians, who found an able prince in Mindog, made occasional incursions. Still Boleslas succeeded in annexing Podlachia. He left the country in a distracted condition, which grew still worse during the short reigns of his successors Lesco II. the Black, a grandson of Conrad, Premislas (Przemyslaw), duke of Posen, who was crowned king at Gnesen in 1295, but soon after murdered by Brandenburgians, and Wenceslas, king of Bohemia, who was elected by the people of Great Poland as a rival to Ladislas the Short (Lokietek), a brother of Lesco II. This prince, who had saved his life once before by escaping in disguise, again became a fugitive, and made a pilgrimage to Rome, but, growing manly, steady, and resolute in misfortune, returned to Poland in 1305, was well received in Cracow and Sandomir (Little Poland), but had to struggle hard against factions in Great Poland and elsewhere, the encroachments of the Teutonic knights, and numerous deeply rooted abuses. He succeeded in restoring order and the unity of the larger part of the country (Silesia subjecting itself to the Bohemian kings); made Cracow its permanent capital, where he was solemnly crowned in 1319; reformed judicial abuses; abolished numerous illegally acquired privileges; convened an assembly of senators, chancellors, regal officers, and other nobles for legislative purposes at Chenciny in 1331, which may be regarded as the first Polish diet (*sejm*); and in alliance with the powerful prince of Lithuania, Gedimin, carried on a vigorous war against the Teutonic knights. Returning from his last campaign, the septuagenarian monarch was justly hailed as the father of his country by the people of the capital, but death followed close upon his triumphal reception (1333). "War against the Teutonic order" was the last advice of the king who had saved and reorganized Poland; peace was the foremost desire of his son Casimir III. the Great, who made it powerful and flourishing. He exchanged the eastern parts of Pomerania, which had been regained under Premislas, for some districts on the Vistula restored by the knights; ceded Silesia to Bohemia for a resignation of further claims, and secured the alliance of Hungary by adopting as successor his nephew Louis the Great, king of that country. Humane and enlightened above his age, though profligate, he earned the title of "king of the peasants," protected the Jews, had a double code of laws for both Polands promulgated by the diet of Wislica in 1347, and founded the university of Cracow, the first in northern Europe. But he also took care to strengthen and extend his power. He built cities and fortresses, and after the death without issue of Boleslas of Masovia, who reigned over Halicz, annexed his vast possessions to the Polish crown. To defend its rights to these provinces, he fought with varying success against Tartars, Lithuanians, and Wallachians. His death (1370) closed the long reign of the Piast dynasty, the first century of which (860–962) may be regarded as half historical, the following 180 years (nearly), from the accession of Miecislas I. to the death of Boleslas Crooked Mouth (1139), as a time of growth and conquests, the 180 years preceding the coronation of King Ladislas I. the Short (1319), as a time of division and decay, and the last period of 50 years as one of reconstruction and renewed expansion.—Louis of Hungary possessed the title, legally conferred by the diet, of Polish king, but hardly deserved it, his policy remaining exclusively Hungarian. He spent all his time in his native kingdom, and even commenced the annexation to it of the Haliczian territories. The legislative rights of the nobles, however, he confirmed and extended, being bent on securing the Polish succession to one of his two daughters, Mary and Hedvig. Of these, the younger, a girl distinguished by beauty as well as piety and mildness of character, was acknowledged after his death (1382), but long remained absent from Poland, which was in the meanwhile a scene of civil war. She finally arrived, and, following the advice of the Polish statesmen, gave her hand to Jagiello, grand prince of Lithuania, conquering not without a struggle an early love for an Austrian duke. The pagan prince was baptized as Ladislas (II.), and promised to convert his people, in which he was assisted by the zeal of Hedvig, and to unite his possessions with Poland. These, the limits of which had been extended by the conquests of his grandfather and father, Gedimin and Olgerd, from the Baltic and the Düna to the Dnieper and Black sea, comprised Lithuania proper, Samogitia (N. of the Niemen), Polesia (on both sides of the Pripetz), Volhynia, Podolia, and Ukraine, and in extent exceeded the territories of Poland, though surpassed by it in population, wealth, and culture. The promised union of the two powerful states was executed gradually and with difficulty. Jagiello, acknowledged as king of Poland (1386–1434), warred successfully against the Teutonic knights, routing them at Grünwald in 1410. His cousin Witold in vain conspired with the emperor Sigismund to make himself independent king of Lithuania under his protection. After the death of Jagiello, however, his elder son Ladislas III. was acknowledged only in Poland, the Lithuanians preferring to be ruled separately under the younger, Casimir. Both were still under guardianship. Ladislas was subsequently elected king of Hungary, and after a successful expedition against the Turks, and a favorable peace concluded under oath, which he was persuaded to break in the interest of religion, fell in a second campaign in the bloody battle of Varna in 1444. His brother Casimir IV. now reigned over both Lithuania and Poland. The first part of his long reign was mostly occupied by campaigns against the Teutonic knights, whose exactions drove the people of eastern Pomerania, or as it was now called Prussia, to rebellion, and in the peace of Thorn (1466) finally surrendered the territories of Dantzic, Culm, and Ermeland to Poland, keeping the eastern part as vassal of that crown. The Polish nobility, who by their bravery decided the protracted contest, simultaneously extended and regulated their rights and legislative privileges; the diets were organized by the institution of preceding district assemblies, and the introduction of regular representation; equality among the warrior class or nobles more and more prevailed; princely and other titles were despised, but family arms generally introduced; in Lithuania alone the higher nobility preserved their titles and oligarchic influence, and their pretensions and turbulent spirit caused numerous troubles, and even grave losses. The long wars were followed by a period of relaxation. Western Prussia, reviving after a dreadful devastation, became a great channel for foreign commerce; luxury, extravagance in dress, and refinement, and the use of foreign languages, including Latin, spread through all classes except that of the peasants. This latter class was still more oppressed during the following short reigns of the sons of Casimir, John (I.) Albert (1492–1501) and Alexander (1501–'6). The former made unsuccessful attempts to limit the sway of the nobles, and only aroused their jealousy and suspicions, an unexpected defeat in the forests of Bukovina during an expedition against Wallachia in 1496 being attributed by them to a plot aiming at their extermination. Under the latter the old and recent enactments, which had already concentrated almost all power in the two houses of the diet, the senate and the more powerful chamber of deputies, were digested in the form of a regular code by the chancellor Laski. Sigismund I., another son of Casimir IV., succeeded (1506–'48). Steady, diligent, active, and a friend of peace, he was the happiest king of his age. He was beloved by the whole people, and obeyed by even the turbulent nobility. The resources of the country were developed, and it attained an unprecedented prosperity, enjoying peace and order while almost the whole of Europe was distracted by wars resulting from religious dissensions or the ambition of princes. The conspiracy of Glinski, an ambitious Lithuanian, however, which was baffled, involved Sigismund in a war with Muscovy, in which Smolensk was lost, though Prince Constantine Ostrogski won a brilliant victory at Orsha. A large part of the Teutonic order having adopted the tenets of Luther, their last grand master Albert of Brandenburg, Sigismund's nephew, was established, as vassal of the latter, duke of eastern Prussia at Königsberg in 1525; the western part of that country, with Dantzic, remained in the immediate possession of Poland, under the name of Royal Prussia. A peace with the Turks, who had advanced to the northern shores of the Black sea, secured the suzerainty of Poland over Moldavia. The tranquillity of the good king was disturbed toward the close of his reign by petty political intrigues of his queen Bona, an Italian princess, and the undeserved complaints of the nobility, who, having been called out for an expedition to Wallachia, assembled in the vicinity of Lemberg, about 150,000 in number, declaimed against encroachments, drew up a list of grievances, and dispersed. Dying soon after, Sigismund left the throne to his son, Sigismund II. Augustus, an inexperienced youth, who had been trained to effeminacy by his mother. But in spite of many foibles, he proved a worthy successor of his father as soon as he was delivered from the maternal tyranny of Bona, who, after persecuting him for some time for having secretly married Barbara Radziwill, finally withdrew with her rich treasures to Italy. So circumscribed was already at that time the power of the king, that the affectionate husband was nearly compelled to sacrifice the crown to his love, and saved both only by timely directing the attention and jealousy of the lower nobility, the so called "younger brethren," to the abuses and encroachments of the higher, the "elder brethren." The reform of the republic, as the state was called, now became one of the principal objects of the diets, another being the final union of Lithuania with the crown. To achieve both the king and the nobles were indefatigable in their endeavors. The Lithuanian lords, however, who gloried in princely titles and enjoyed great feudal privileges, were slow in submitting to Polish equality; but Sigismund Augustus set a good example by sacrificing his own feudal as well as hereditary rights. After the death of Nicholas Radziwill the Black, one of its principal opponents, the union was proclaimed by the diet of Lublin in 1569. Ostrogski, Czartoryski, and other powerful Lithuanians signed it. Lithuania ceased to be a hereditary possession of the house of Jagiello, but was to form a common republic with Poland, under the rule of an elective king, with a common diet and senate. The two component parts, however, the grand principality and the crown, maintained their separate titles, armies, finances, and statutes. Podlachia, Volhynia, and Ukraine were transferred from the former to the latter.

Livonia, recently conquered by Sigismund Augustus from the knights sword-bearers, and defended against Ivan the Terrible of Muscovy, remained a common duchy. Warsaw in Masovia was chosen to be the regular seat of the diet. The power, prosperity, and opulence of the state approached their height. Peace promoted commerce, refinement, and the development of literature in both Latin and the vernacular Polish, which also gradually took the place of the Russian in the Lithuanian parts. Toleration and hospitality attracted foreigners of all sects, Lutherans, Calvinists, and Socinians, while western Europe was the scene of internecine religious strifes. The population of Poland was doubled under the two Sigismunds. But, a prey to disease, and to male and female favorites and charlatans, the younger died poor in rural solitude, and without issue, the last in the male line of the Jagiellos, the happiest of all the Polish dynasties (1572). During the interregnum which now followed, the cardinal rights of the nation were established, each elective head being required to enter into a regular covenant with it and to take the oath of fidelity to the *pacta conventa.* He was bound to convoke the diet every two years, to have a permanent council consisting of senators and deputies, to respect the rights of the dissidents, not to declare war or to send ambassadors abroad without the consent of the estates, and not to marry without that of the senate. An infraction of the compact was to absolve the people from allegiance. A diet of convocation, assembled by the archbishop of Gnesen as primate, preceded the diet of election, which was held on the field of Wola before Warsaw, every nobleman having an individual and equal elective vote. The archduke Ernest, a member of the then all-annexing house of Austria, and others found little sympathy; the choice fell upon the most unworthy candidate, the profligate Henry of Valois, duke of Anjou, brother of Charles IX. of France. A splendid embassy escorted the duke from Paris, and a splendid coronation took place at Cracow, in 1574; but the effeminate prince and the hardy nation were soon heartily disgusted with each other; and after a few months, having received the news of the death of Charles, he secretly ran off to France to succeed him as Henry III. Another Hapsburg, the emperor Maximilian II., appeared as candidate, and was even arbitrarily declared elected by the primate Uchanski; but the great statesman John Zamojski proposed to give the crown to Anna Jagiello, an elderly and virtuous sister of Sigismund Augustus, choosing for her husband Stephen Báthori, prince of Transylvania, and his advice prevailed (1575). This Transylvanian was probably the ablest monarch Poland ever had. A zealous Catholic himself, he was animated by a spirit of toleration toward others, and as a patron of science and friend of education founded numerous institutions, among others the university of Wilna, which he intrusted to the Jesuits. He reformed the judiciary, instituting independent high tribunals, strengthened the military forces of the country, secured the friendship of the Tartars around the Black sea, organized the Cossacks of the lower Dnieper as guardians of the S. E. frontier, and in a war against Russia humiliated Ivan and conquered Polotzk. His principal adviser and right arm was John Zamojski, who united the dignities of chancellor, castellan of Cracow, and hetman or commander-in-chief. Though a favorite also of the nation, he aroused the anger of the nobility against the king by an act of extreme though just severity, the execution of Samuel Zborowski, for murder and rebellious conduct; and Báthori, who frequently made use of Hungarian troops, was suspected of aiming at the subversion of the constitution and the establishment of a strong, hereditary monarchy, when he died. He closed the period of Poland's greatest power and prosperity, which, commencing with the accession of the house of Jagiello, lasted full 200 years. The independence of Poland survived this period for two more centuries, but these were a time of almost continual decay. Sigismund Vasa, the Swedish crown prince, who by his mother was a descendant of the Jagiellos, and an Austrian archduke, Maximilian, were the principal candidates after Báthori. Zamojski carried the election of the former, but his enemies the Zborowskis and their followers declared for the latter. The hetman, however, routed the archduke's troops, made him prisoner, and compelled him to resign. Still Sigismund, a friend of the Jesuits, whose Catholic zeal cost him his hereditary Swedish crown, entered into close alliance with Austria, like many of his predecessors marrying a princess of that house. His long reign (1587-1632) was distinguished by great men and numerous wars, but by no favorable results. In his first war against Sweden, where his uncle Charles IX. occupied the throne, he lost almost the whole of Livonia, in spite of Zamojski's successes and Chodkiewicz's brilliant victory at Kirchholm in 1605. Mniszech, Wisniowiecki, and others in vain sacrificed their men and riches to set the daughter of the former, Maryna, together with the Pseudo Demetrius on the throne of Moscow; the pretender fell by the Shuiskis in 1606; Zolkiewski, the heroic Polish hetman, took the latter prisoners, and had his king's son Ladislas crowned as czar in 1610; but Sigismund, who aimed at converting Russia, spoiled the affair by a separate expedition, and all but Smolensk and Severia was lost again. Zamojski successfully interfered, at his own expense, in the affairs of Moldavia, but other powerful nobles who followed his example were made captives by the Turks. Zolkiewski conquered peace from the Turks, but fell in a new war at Cecora in 1620. Chodkiewicz revenged his death at Chocim, where he closed his glorious career in 1621. In anther war against Sweden, when Sigismund counted, but in vain, on Austrian and Spanish aid against the common enemy Gustavus Adolphus, not only was Livonia not reconquered, but Riga was lost (1621), the Polish fleet on the Baltic destroyed, and a part of Prussia given up by a truce in 1629. In internal affairs Sigismund was not more successful; the Greeks and other dissidents complained, conspired, or rebelled, the regular army extorted its arrears by mutiny, and the royal dignity was more than once humiliated. Sigismund's brave son, Ladislas IV. (1632–'48), defended Smolensk against Russia, and regained Prussia in a peace concluded with Sweden in 1635, but in domestic concerns was not more fortunate than his father. Having by some intended reforms caused suspicion among the nobility, he had to submit to further limitations of the regal authority. The dominant class, the turbulent warrior brotherhood, now exercised its sway in every direction, tyrannically disabling the king, prohibiting superior titles, entirely excluding the non-nobles from all legislative influence, and more and more burdening and degrading the peasantry. Similar oppression, as well as religious persecution, was now begun against the Cossacks, which at the time of Ladislas's death resulted in a dreadful rising under Chmielnicki, who, aided by the Tartars, carried death and desolation into the very heart of Poland, alternately conquering and conquered in battles, extorted treaties and submitted to others, and finally subjected the rebellious warriors to the czar of Moscow. This war and defection, next to the spirit of religious intolerance which cursed the reign of the Vasas the principal cause of Poland's rapid decay, was only one of the calamities which befell the brother and successor of Ladislas, the religious and brave but fickle John (II.) Casimir (1648–'68). Some he caused himself by injustice, as the treason of Radziejowski, and the fatal insurrection under Lubomirski; but the chief sources of misfortune were legislative anarchy, culminating in the *liberum veto*, or the right of a single deputy to prevent or annul the action of the diet, internal dissensions, and the readiness of neighboring powers to profit by them, which made John Casimir prophetically predict in the diet the future dismemberment of the country by Brandenburg, Austria, and Russia. In his own reign, simultaneously assaulted by the Russians and Cossacks, Charles Gustavus of Sweden and his ally the great elector of Brandenburg, and George Rákóczy of Transylvania, Poland was on the brink of ruin; the new capital, Warsaw, as well as the old, Cracow, fell into the hands of the Swedes, Wilna and Lemberg into those of other enemies; the king was deserted, and fled to Silesia. The fortified convent of Czenstochowa, however, was saved by the patriotism of the friars; a confederation for defence was formed at Tyszowce by the Potockis, Lanckoronski, and other patriots; heroic efforts were made, John Casimir returned, the king of Denmark proved a useful ally, and the sword of Czarniecki was victorious everywhere and against all enemies, from Cracow to Slonim, and from the coast of Denmark to the shores of the Black sea. Peace was conquered, but at great sacrifices. Ducal Prussia was definitely ceded to Brandenburg, almost all Livonia to Sweden, and Smolensk, Severia, Tchernigov, and Ukraine E. of the Dnieper to Russia, by the treaties of Wehlau, Oliwa (1660), and Andrussow. Poland was half a desert. John Casimir, despairing of the future, resigned, and retired to an abbey in France, where he died. Michael Korybut Wisniowiecki was elected his successor. He was the son of a commander who made himself terrible to the Cossacks in the wars of the preceding reign, but himself possessed neither distinction, nor wealth, nor confidence in his own abilities, and had almost to be compelled to accept the crown. The primate and the hetman John Sobieski openly and secretly agitated against him; and when on an incursion of the Turks, in which they overran Ukraine and Podolia and captured Kamieniec (1672), he concluded with them a shameful peace, Sobieski caused its rejection by the senate, immediately hastened to the seat of war, and routed the Moslems at Chocim (1673). Michael dying about the same time, the hero repaired to the diet at Warsaw, was himself elected his successor, returned to meet the foe, and relieved the hard-pressed fortress of Trembowla. In another campaign, however, he was surrounded by the Turks and Tartars at Zurawno and barely saved his army, ceding Kamieniec and a part of Ukraine in a treaty. At the instigation of his ambitious and intriguing French queen, he again took up arms against the Turks in 1683, when he delivered Vienna and filled Christendom with the fame of Polish arms, but obtained no benefit for his own country. Equally fruitless were his later undertakings, and he died little beloved by his people in 1696. His sons found no support at the election; the diet was divided, and two foreigners, the prince of Conti and the elector of Saxony, Augustus (II.), were elected by the opposing factions. The elector arrived before Conti, and prevailed. His friendly relations with the court of Vienna enabled him to regain Kamieniec, without a war, through the treaty of Carlowitz (1699); but his alliance with Peter the Great of Russia and Frederic IV. of Denmark, against the young Charles XII. of Sweden, proved a source of calamities to himself and the country. The Saxons fought Augustus's battles, and the Poles, who had not been consulted about the war, were little inclined to aid him. Charles, having humbled the Danish king at his capital, and routed the czar at Narva in 1700, drove back the Saxons from the Düna, marched through Lithuania, where he was received with open arms by the Sapiehas, who were just engaged in a bloody feud against other families of the grand principality, crossed over to Poland, entered Warsaw, defeated Augustus at Klissow in 1702, and occupied Cracow. The young conqueror preferred giving away the crown of Poland to taking it himself, and had his friend, the youthful and noble-hearted palatine of Posen, Stanislas Leszczynski, substituted for the voluptuous Saxon (1705), whom he pursued into his hereditary electorate, where by the treaty of Altranstädt in 1706 he compelled him to resign his claims to Poland. But scarcely had Charles lost the battle of Pultowa (1709), when Augustus returned, and with the help of the Russians recovered the regal crown. Stanislas joined his protector in Turkey. The following period of peace was one of public and private corruption. The nobility was infected by the effeminacy of the court, and abandoned the defence of constitutional rights; religious fanaticism not only occasionally showed itself, as at Thorn in 1721, in a bloody shape, but also legalized the long exercised exclusion of the dissidents from office; and Russian interference became permanent. A Russian army helped a faction of the nobles to establish the son of Augustus as his successor in 1733, instead of the reëlected Leszczynski, who was compelled to retire to Dantzic, where he was besieged, and thence to escape in disguise. Louis XV. of France, who had married the daughter of Leszczynski, commenced a war of Polish succession on the Rhine, at the termination of which the latter received the duchy of Lorraine, but Augustus III. remained on the throne of Poland, continuing in peace the enervating misrule of the preceding reign. During the 7 years' war Russian armies crossed and recrossed the country without opposition. Constitutional anarchy made legislation almost impossible. But already the more enlightened of the nation, seeing the depth of degradation into which the country was sunk, began to think of vital reforms. Not only was the *liberum veto* attacked by the great Piarist Konarski and others, but monarchical opinions too gained considerable ground. To transform the republic of the nobles into a regular constitutional kingdom became the scheme of Michael and Augustus Czartoryski and their friends. In order to conquer the opposition of Radziwill, the Potockis, and other adherents of the old republican constitution, they secretly sought the aid of Catharine II. of Russia, who readily but treacherously granted it. After the death of Augustus III. in 1763, Stanislas Augustus Poniatowski, a favorite of the empress, and nephew of the Czartoryskis, was illegally placed upon the throne by a confederation of the reformers, aided by Russian bayonets. The regal prerogative was somewhat enlarged. The commencement of the new reign was splendid and promising. But Poniatowski, though enlightened, good-natured, and a friend of progress and literature, was feeble to fickleness, and allowed himself to be used as a tool by the designing empress. Her ambassador, Repnin, who had an army at his disposal, became the real ruler. He encouraged the dissidents and enemies of reform, who formed numerous small confederations, united them into one at Radom, and by force of arms compelled them to accept the guaranty of the unlimited republican liberty by Russia. To silence the indignation of the people, he had the patriotic bishops of Cracow and Kiev, Soltyk and Zaluski, and the palatine of Cracow, Rzewuski, with his son, arrested in the night, and sent as prisoners to Russia in 1767. The patriots, however, now took up arms in defence of independence and liberty, against foreign aggression and regal usurpation, but unhappily also against the influence of the dissidents. The confederation of Bar took the lead (1768), its soul being the Pulaskis (properly Pulawskis), especially Casimir, and Krasinski, bishop of Kamieniec. The struggle against the Russians, the Porte too declaring war against them, was carried on long and fiercely in various parts of the country, but only by a part of the nobles, under Pulaski, Sawa, Charles Radziwill, Zaremba, Kosakowski, Oginski, and others. An attempt in 1771 to carry off the king from the capital failed when almost executed, and brought great odium upon the confederates. Meanwhile Catharine concerted a division of Poland with Frederic the Great and Maria Theresa. The Prussians and Austrians entered Poland in 1772; the confederates, already greatly weakened, dispersed, and the dismemberment of the country began. A diet was convoked in 1773 to sanction the deed; but few of the members appeared, and these remained silent. Russia took the palatinates of Polotzk, Vitebsk, and Mstislav, and some adjoining parts; Prussia, the Polish province of that name, with the exception of the towns of Thorn and Dantzic, and a part of Great Poland on the Netze; Austria, Red Russia, a part of Podolia, and parts of Little Poland between the Vistula and the Carpathians, uniting all under the name of Galicia and Lodomeria. The old constitution with all its abuses was fastened upon the remaining territories of Poland, under the guaranty of Russia. To save and strengthen the country by reforms now became a general tendency, and in a short time an immense progress was achieved in culture, literature, commerce, industry, and legislation. The general reform of the state was the task of the double diet of 1788–'92, called the great or long diet, and presided over by Malachowski and Sapieha, which by a new constitution, first promulgated May 3, 1791, and most solemnly adopted by the king and the people, abolished the *liberum veto*, gave political rights to the cities and civil rights to the peasantry, and made the throne hereditary, offering the succession to the elector of Saxony. Frederic William II. of Prussia encouraged the reformers, and offered his aid against Russia. But the aid of Catharine II. was invoked by the defenders of the old constitution, who under the lead of Felix Potocki, Francis Xavier Branicki, and Severin Rzewuski, in 1792 formed the confederation of Targovitza against the new order of things. The Russians entered Poland; the Polish army, commanded by Joseph Poniatowski, the nephew of the king, retreated to the Bug; the arrival of the king in person was waited for in vain; Prussia proved traitorous, and Kosciuszko's glorious fight at Dubienka (July 17) was useless. After long wavering, the king virtually ended the struggle by going over to the confederation; the Russians occupied the capital, and a diet convened by the victors at Grodno in 1793 was compelled at the point of the bayonet to sanction a new division of the country. The ostensible defender of the old "republican liberty," Catharine, with her own hand drew a line on a map across Lithuania and Volhynia, taking all the land E. of it; the late ally of Poland, Frederic William, secured himself against "Polish Jacobinism" by taking the remainder of Great Poland and the towns of Thorn and Dantzic. The despair of the nation broke out in a great insurrection in 1794, for which the brigadier Madalinski gave the first signal. Kosciuszko was called from abroad to lead it as dictator, and, appearing at Cracow, hastily armed the people of the vicinity, partly with pikes and scythes, and routed the Russians at Raclawice (April 4). The Russian garrison at Warsaw, commanded by Igelström, was soon after almost annihilated by a revolt of the inhabitants under the lead of the shoemaker Kilinski; a supreme council was formed, embracing among others Ignatius Potocki and Kollontaj; Lithuania rose under Jasinski; numerous scattered detachments of troops flocked to the banner of Kosciuszko; the king was ignored. But the means of the exhausted country were scanty, arms were wanted, unanimity could not be produced, and the Russians were soon joined by Prussian and Austrian armies. Kosciuszko was defeated at Szczekociny, and Zajonczek at Chelm. Warsaw was besieged by Frederic William in person, and distracted by popular outbreaks of rage against real or presumed traitors; and though it was saved by a rising, under Mniewski and Dombrowski, in the rear of the Prussians, Kosciuszko was no longer able to prevent the junction of the Russian corps under Suwaroff and Fersen, and in the bloody battle of Maciejowice (Oct. 10) was taken prisoner. The storming and massacre of Praga and the capitulation of Warsaw (Nov. 8) followed; the Polish troops were disbanded; most of the commanders and numberless other patriots were dragged into captivity; and Poniatowski resigned his crown at Grodno in 1795, and died brokenhearted at St. Petersburg (1798). The third division annihilated the existence of Poland, effacing even its name. Russia took all the provinces E. of the Niemen and Bug; Austria those between the latter river, the Pilica, and the Vistula; Prussia all the remainder, with its capital. But scarcely had the last dismemberment been consummated, when the surviving patriots commenced making new endeavors for the restoration of their national independence. Secret conferences took place in the Polish provinces, and committees were appointed abroad, the principal being at Paris and Venice. Oginski and others invoked the help of France, Turkey, and Sweden, and Dombrowski succeeded in forming in revolutionized Italy Polish legions, whose bravery soon rivalled that of the most renowned French troops under the banners of Napoleon. After 10 years' glorious service abroad they victoriously reëntered their native land. By the treaty of Tilsit (1807) Napoleon transformed the greater part of the Prussian share of Poland into a duchy of Warsaw, which received a tolerably liberal constitution, and a ruler in the person of the king (formerly elector) of Saxony, Frederic Augustus. This little Polish state made immense exertions in behalf of its French ally and protector, and the Polish armies under Prince Joseph Poniatowski, Dombrowski, Zajonczek, Chlopicki, and others, shed their blood profusely not only on their own soil, as in the last war against Austria (1809), when the duchy gained a large part of western Galicia, but also in Spain and elsewhere, and especially in the great Russian campaign of 1812, which promised the restoration of the whole of Poland. This hope soon vanished with the reverses of the grand army, and the duchy itself was destroyed in 1813, after a gallant resistance by the fortresses of Zamosc, Modlin, and Thorn. Poniatowski perished in the Elster at the close of the battle of Leipsic, but the remnants of the Polish troops fought to the last with the retreating emperor, and some followed him even to Elba. The territorial limits of divided Poland were now rearranged by the congress of Vienna, which, while creating a shadow of Polish independence in the miniature republic of Cracow, naturally gave the lion's share to Alexander of Russia. The czar, flushed with victory and popularity, formed his new acquisitions, extending from the Niemen and Bug to the Prosna, into the present so called kingdom of Poland, to which he gave a constitution guaranteeing a biennial diet, composed of a senate for life and a chamber of deputies, a separate responsible ministry, an independent judiciary, a national army of 50,000 men, and the freedom of the press. Of this separated and privileged part of his vast Polish possessions the czar was the king, and his brother Constantine, its military governor and generalissimo, the virtual viceroy, Gen. Zajonczek being the nominal. Most of the surviving Polish officers of the Napoleonic armies took service in the national ranks. But the harmony between the foreign rulers and the people could be but superficial, and even as it was but of brief duration. Mutual distrust prevailed from the beginning; the opposition to the measures and projects of the government gained strength from diet to diet; violations of the constitution grew frequent, as the more or less sincere liberalism of Alexander declined as he grew older; Constantine tortured the army by excessive drilling, and drove the best officers from its ranks and into hostility by outrageous insults; secret patriotic affiliations were formed in various Polish provinces by Dombrowski, Uminski, Lukasinski, Zan, Krzyzanowski, and others; numerous victims of the terribly organized secret police were thrown into dungeons or transported to Siberia; and after the accession of Nicholas (1825) there could be no longer any doubt that an open rupture was only a matter of time. Nevertheless the outbreak at Warsaw, precipitated by a small band of youthful democratic conspirators under Peter Wysocki, which drove Constantine and the Russians in the night from that capital (Nov. 29–30, 1830), took both the emperor and the nation by surprise, though ensuing 4 months after the revolution of July in Paris. The whole people immediately declared in favor of the revolution, but the aristocrats took the lead with the intention of moderating its course. To this party belonged the patriotic Prince Adam Czartoryski, president of the provisional government; the old poet Niemcewicz, formerly Kosciuszko's companion in arms in America and Poland; the minister Lubecki, a man of dubious patriotism; Chlopicki, for a short time dictator (Dec. 1830, Jan. 1831); his successors in the chief command of the army, Radziwill, Skrzynecki, Dembinski, and Casimir Malachowski; and the generals Dwernicki, Chrzanowski, Bem, Uminski, Rybinski, Prondzynski, and others. The agitations of Lelewel, Mochnacki, and other democrats, in the diet or clubs, had no other result but an increase of difficulties, and finally fatal disorder. Much precious time was wasted in attempted negotiations with Nicholas; the ardor of the masses was checked by too long continued observance of constitutional and territorial limits; the peasantry was left in its degraded condition; the army increased slowly; the sending of troops into Lithuania, which was anxious to rise, was delayed until it was too late; and a powerful Russian army under Diebitsch was allowed to cross the Bug without resistance, and to approach the capital. The independence of Poland and the exclusion of the house of Romanoff having been declared (Jan. 25), a series of bloody battles was fought mostly in the vicinity of Warsaw, especially at Dobre, Wawre, and Grochow, and at Stoczek, in February, again at Grochow in March, at Iganie in April, and on the middle Narew and Bug and at Ostrolenka in May, in which the personal courage of the Polish commanders was far more conspicuous than their strategetic talents. The bravery of soldiers, of whom a part could be armed only with scythes, never shone brighter in any other contest. But the time of dearly purchased victories and glorious defeats was now over; Dwernicki, sent to revolutionize Volhynia, had been compelled to retire into Galicia, and there to surrender to the Austrians; another corps, sent under Gielgud and Chlapowski to the assistance of the Samogitian and Lithuanian insurgents, shared the same fate on Prussian territory in July, Dembinski alone saving his detachment by an admirable retreat; the main army remained inactive around the capital, allowing the new Russian commander-in-chief Paskevitch to cross the lower Vistula on the Prussian frontier, and to advance toward Warsaw on the left bank of that river. The people growing impatient, Skrzynecki was deposed, presumed traitors were massacred in a night of horrors (Aug. 15), and Krukowiecki succeeded Czartoryski as president of the government, but the management of affairs grew even worse than before. Ramorino having been sent to the S. E. with a part of the Polish army, Paskevitch finally attacked the fortified capital, and after a murderous struggle, during which Krukowiecki negotiated, a capitulation virtually ended the war (Sept. 8). The main army under Rybinski, accompanied by the government under Niemojewski, laid down its arms on Prussian territory; Ramorino in Galicia, a corps under Rozycki at Cracow, and the fortresses of Zamosc and Modlin surrendered. Depopulated at once by the sword and by the no less frightful ravages of cholera, the country lay bleeding and exhausted at the feet of the czar, and mercy was neither expected nor exercised. Numberless patriots were sent to Siberia and other places of confinement, the private soldiers compelled to serve in the Russian army, the estates of refugees confiscated, the constitution and the laws of the country abrogated, the university of Warsaw and other principal schools abolished, the rich literary collections carried to St. Petersburg, all marks of nationality prohibited, the most rigorous censorship of the press and a terrible police system introduced, a citadel at Warsaw and other new fortifications erected, the most arbitrary measures taken to denationalize and Russianize the people, and new attempts at insurrection in 1833 and 1846 punished with the gallows. This system was continued throughout the reign of Nicholas, though at times moderated by the milder disposition of the governor, Paskevitch. The same denationalizing policy was zealously prosecuted in all other Polish provinces of Russia, Prussia, and Austria; the republic of Cracow alone preserved for some time its nationality. In the meanwhile the Polish emigrants, residing mostly in France, and embracing the most distinguished men of the nation, though split into violently opposing factions, were unremitting in their endeavors to pave the way for a restoration of their country. The democratic party, consisting chiefly of the younger generation, partook in numerous revolutionary movements in western Europe, and fomented conspiracies in Poland. The most extensive and best organized of the latter, led to simultaneous outbreaks in Russian Poland, Galicia, Cracow, and Posen (Feb. and March, 1846). All ended disastrously. The leaders in Poland were hanged, those in Posen, Mieroslawski and others, imprisoned, and the patriotic nobles of Galicia butchered by the peasants; the republic of Cracow, where alone the insurrection was for a short time successful, was abolished and annexed to Galicia. Mieroslawski and his associates, being saved from death by the revolution of Berlin in March, 1848, fought soon after, with hastily collected Polish bands, bravely but unsuccessfully, against overwhelming Prussian forces in Posen; Bem, Dembinski, and Joseph Wysocki commanded Hungarian armies and Polish volunteers against Austrians and Russians in 1848–'9; Czajkowski and others fought against the latter in the Turkish war; but all those efforts directly or indirectly to benefit Poland from abroad remained fruitless. At home, however, considerable ameliorations took place in the Russian Polish provinces after the accession of Alexander II. (1855), numerous refugees returned, and new reforms were hoped for, when a gradually increasing agitation and lively popular demonstrations at Warsaw on Feb. 27 and April 8, 1861, induced the new governor, Gortchakoff, after some concessions, to employ the military force, and a large number of lives were sacrificed. Similar demonstrations and more or less serious collisions took place in other parts of the country. Simultaneously a Polish diet was convened at Lemberg (April 15), Austria having been compelled by the consequences of the Italian war of 1859, and especially the new movements in Hungary, to grant constitutions to its various provinces.—Among the principal works on the history of Poland are, in Polish, those of Naruszewicz, Niemcewicz, Bandtke, and Lelewel; and of Oginski, Rulhière, Salvandy, Bronikowski, Soltyk, Brzozowski, Roepell, Mieroslawski, and L. Chodzko in other languages.

POLAND, LANGUAGE AND LITERATURE OF. The Polish language belongs to the northwestern group of the Slavic division of Indo-European tongues. Its principal dialects, though not materially differing from each other, are those of Masovia, Little Poland and Galicia, Lithuania, and Great Poland, beside the more degenerate Silesian. The alphabet consists of the following letters: *a* (short Italian *a*), *ą* (French *on*), *b*, *ḃ* (soft, like Eng. *by*, both consonant), *c* (*ts*), *ć* (*tch*, very soft), *cz* (*tsh*), *ch* (*ch*, Ger. *ch*), *d*, *e* (short Italian), *é* (compressed, as in *yes*), *ę* (Fr. *in*), *f*, *g* (hard), *h*, *i* (short Italian), *j* (*y* consonant), *k*, *ł* (*l*, very hard), *l* (It. *gl*), *m*, *n*, *ń* (Fr. *gn*), *o* (short Italian), *ó* (compressed, approaching *u*), *p*, *ṗ* (soft, like *py*, both consonant), *r*, *rz* (Fr. *rj* in one), *s*, *ś* (*sh*, very soft), *sz* (*sh*), *t*, *u* (short Italian), *w* (*v*), *x*, *y* (resembling the Ger. ü), *z*, *ż* (Fr. *j*), *ź* (Fr. *j*, very soft). *I* serves to soften various consonants, replacing the ´: *drób*, little poultry, gen. *drobiu*; *żyć*, to live, *życie*, life; *koń*, horse, gen. *konia*; *wieś*, village, gen. *wsi*. The accent, except in foreign words and in compounds, is constantly on the penultimate: *rodak*, countryman, gen. *rodaka*, dat. *rodakowi*. As in Latin, there is no article: *cnota*, virtue, a virtue, the virtue. There are 7 cases of declension, nominative, genitive, dative, accusative, vocative, instrumental (*mieczem*, by or with the sword), and locative (after certain prepositions, as *w Bogu*, in God). The forms of declension depend upon the termination, the gender, and the kind, words of the same termination denoting persons, animals, and lifeless objects having in the masculine severally different forms. The gender of nouns is mostly determined by the termination. There are three genders for nouns, adjectives, pronouns, verbs, and participles, as: *Mój dobry kochany ojciec pisał*, My good beloved father wrote; *Moja dobra kochana matka* (mother) *pisała*; *Moje dobre kochane dziecko* (child) *pisało*. The following may serve as examples of the declension of nouns and adjectives in the masculine and feminine singular: *wielki las*, (a, the) large forest, *wielkiego lasu*, *wielkiemu lasowi*, *wielki las*, *wielki lesie!*, *wielkim lasem*, (*w*) *wielkim lesie*; *wielka rzeka*, (a, the) large river, *wielkiej rzeki*, *wielkiej rzece*, *wielką rzekę*, *wielka rzeko!*, *wielką rzeką*, (*w*) *wielkiej rzece*. The comparative degree is formed by the syllable *szy* (nom. mas. sing.), the superlative by *naj* and *szy*, thus: *stary*, old, *starszy*, older, *najstarszy*, oldest; *mocny*, strong, *mocniejszy*, *najmocniejszy*. The numerals distinctly betray a pure Indo-European derivation: *jeden* (Sans. *eka*, compare also the Heb. *echad* and the Hung. *egy*), *dwa* (Sans. *dva*, Gr. *δύο*, Lat. *duo*), *trzy* (Sans. *tri*, Gr. *τρεῖς*, Lat. *tres*), *cztery* (Sans. *tchatur*, Lat. *quatuor*), *pięć* (Sans. *pantchan*, Gr. *πέντε*), *sześć* (Sans. *shash*, Lat. *sex*, comp. Heb. *shesh*), *siedm* (Sans. *saptan*, Lat. *septem*, comp. Heb. *sheba'*), *ośm* (Sans. *ashtan*), *dziewięć*, *dziesięć* (Sans. *das'an*, Lat. *decem*), *sto* (Sans. *s'ata*, Lat. *centum*), *tysiąc* (*thousand*). The verb is exceedingly rich in forms, serving to express frequency, intensity, inception, duration, and other modes of action or being. The formatives consist chiefly of prepositions and other particles, as in German, thus: *znać*, to know, Ger. *kennen*; *poznać*, to recognize, Ger. *erkennen*; *rwać*, to tear, *wyrwać*, to snatch, Ger. *entreissen*; *rozerwać*, to tear asunder, Ger. *zerreissen*; *rozrywać*, long or frequently to tear asunder; *porozrywać*, to tear asunder to the last. *Ć* marks the infinitive, *ł* the past: *znam*, I know, *znać*, to know, *znałem*, I knew; the persons are distinguished by the termination: *znam*, I know, *znasz*, thou knowest, *zna* (he, she, it) knows, *znamy*, *znacie*, *znają*, we, you, they know. Diminutives, denominatives, and other derivatives, are abundant. Compounds are rare. The words of a sentence can be arranged almost as freely as in Latin, misunderstanding being precluded by the distinctness of the formative terminations. In flexibility, richness, power, and harmony the Polish is hardly excelled by any other language of Europe; its grammatical structure is fully developed and firmly established, its orthography precise and perfect. The principal grammars are by Kopczynski, Mrongovius, Bandtke, Mrozinski, Poplinski, and Muczkowski (Cracow, 1845); the principal dictionaries by Linde, Bandtke, Mrongovius (Königsberg, 1835), and Trojanski (Posen, 1835–'46).—The oldest remnants of Polish literature consist of proverbs, popular songs and tales, and a religious song in praise of the Virgin (*Boga rodsica*) attributed to St. Adalbert (Sty. Wojciech), who lived in the time of the first Christian monarch of Poland, toward the close of the 10th century. The Latinizing influence of Christianity, and of the universities of western Europe, which were generally frequented by the Poles, prevented the development of a national literature in Poland during the middle ages; and all the literary productions of that period, as well as the laws of the country, were written in Latin. Among the most important of the former are the chronicles of Martin Gallus (about 1130), Kadlubek (1220), Boguphalus (1250), and Martin Skrzenbski, surnamed Polonus (1270), and the celebrated "History of Poland" by Dlugosz (1480). The principal centre of scholarship and science was the university of Cracow, the first foundation of which was laid by Casimir the Great (1347), and which among its teachers and alumni counted some of the most distinguished scholars of Europe, among others Copernicus, whom Poland claims as its son and citizen. The first Polish printing press was established at Cracow toward the close of the reign of Casimir IV. (1490). Among its earliest productions is the great collection of Polish laws by the chancellor of King Alexander, John Laski (1506). In the succeeding reigns of Sigismund I. and his son Sigismund Augustus, the last two of the Jagiellos (1506–'72), Polish literature was first and rapidly developed, the 16th century being regarded by many as its golden age. The poetical style especially rose to an astonishing degree of perfection. The satirist Rej (born 1515), and John Kochanowski, the great lyrical poet (1532–'84), are both called the fathers of Polish poetry. Of the two younger brothers of the latter, Peter translated Tasso's "Jerusalem Delivered," and Andrew Virgil's Æneid. The poets Szarzynski, Rybinski, Klonowicz, Miaskowski, and Grochowski were contemporaries of the Kochanowskis. The reformation, which found an easy spread in Poland, caused numerous translations of the Bible into the national language, for Lutherans and Socinians as well as for Catholics. Among the theologians of that age the great Catholic pulpit orator Skarga (died 1612), and the Protestant author Niemojewski, deserve particular mention. Martin and his son Joachim Bielski, in the latter part of the 16th century, wrote a *Kronika polska*, Górnicki (1535–'91) *Dzieje w koronie polskiej* ("History of the Polish Crown Lands"), Stryjkowski (died 1582) a "Chronicle of Lithuania," and Paprocki (died 1614) works on heraldry. Others wrote in Latin: Orzechowski the *Annales Poloniæ*; Kromer, archbishop of Ermeland (died 15[illegible]), *De Origine et Rebus Gestis Polonorum*. Szymonowicz (Simonides), an author of celebrated Latin odes, and of equally excellent Polish idyls (*Sielanki*), and Zimorowicz, his rival in the latter species of composition, flourished during the reign of Sigismund III. (1587–1632); but in the second half of that reign Polish literature began rapidly to decline. The Latin was the principal object and medium of instruction. The disastrous wars and civil strifes of that and the following reigns of the Vasa dynasty exercised a pernicious influence. Sobieski restored only the glory of Polish arms, and the succeeding Saxon rule inaugurated a period of general relaxation. During a century and a quarter pedantry, bad taste, and impurity of language prevailed. Of the better poets of that epoch may be mentioned the Jesuit Sarbiewski (Sarbievius, died 1640), who wrote in Latin odes and earned the title of the Sarmatian Horace; Opalinski, a writer of satires (died 1655); Twardowski (died 1660); Kochowski, who accompanied John Sobieski to Vienna, and in *Wieden wyzwolony* ("Vienna Delivered"), an epic, sang the glory of his hero; Bardzinski; Morsztyn, the translator of Corneille; and Elizabeth Druzbacka (1687–1760), whose *Pochwala lasu* ("Praise of the Woods"), *Cztery pory roku* ("The Four Seasons of the Year"), &c., appear as the precursors of a better literary age. The historians wrote mostly in Latin: Piasecki (1585–1649) a liberal history of his times (*Chronicon Gestorum in Europa*); Starowolski (died 1656), among other works, a *Status Regni Poloniæ Decriptio*; Kojalowicz (died 1677) an excellent *Historia Lithuaniæ*; Fredro (died 167[illegible]) his *Fragmenta*; Andrew Wengierski (died 16[illegible]), and Lubieniecki (died 1675) histories of the reformed church in Poland. Among those who contributed most to the introduction of a better era were the brothers Joseph and Andrew Zaluski; the former, who was bishop of Kiev (died 1774), especially by the collection of a library of more than 200,000 volumes. More powerful still was the influence of the great reformer of public education, the Piarist Konarski (died 17[illegible]). The courts of the exiled king Leszczynski in Lorraine, and of Poniatowski in Warsaw, as well as the residences of the princes Czartoryski and Jablonowski, were centres around which the representatives of reform in politics, social life, education, literature, and science grouped themselves. The politically unhappy reign of Poniatowski, the last king of independent Poland, thus became in a literary point of view the most distinguished. Piramowicz wrote for schools; Bohomolec translated French dramas; Trembecki, Kniaznin, and Wengierski composed fine lyrical or descriptive poems; Naruszewicz a great "History of Poland" and an admirable translation of Tacitus; and the genial Krasicki miscellaneous works in verse and prose, by which he merited the distinction of being called the Voltaire of Poland. This purified literary activity survived the divisions and fall of Poland. The poets Godebski Wenzyk, author of *Okolice Krakowa* ("The Environs of Cracow"), and Dmochowski, the dramatists Felinski, Kropinski, Osinski, and Boguslawski, and the eminent historical or political writers Czacki, Albertrandy, Kollontaj, Stanislas Potocki, Ossolinski, and Staszyc, belong principally to the beginning of the present century. The most popular poets of the next following period were Karpinski, Brodzinski, Woronicz, and especially Niemcewicz, who was also distinguished as a historian, and in his ballads (*Spiewy historyczne*) surpassed all his predecessors. He was, however, soon after himself surpassed in epic poetry by Mickiewicz, the founder of the romantic school of Polish poetry, around whom numerous young disciples grouped themselves at Wilna. To the romantic school belong most of the more recent poets of Poland, many of whom wrote, after the revolution of 1831, in exile; the Ukrainians Malczewski, author of the admirable epic "Maria," Goszczynski, Zaleski, and Padura; Odyniec, author of the drama of *Izora*; Korsak, who wrote elegiac poetry and lyrics; Alexander Chodzko, translator of Persian and other oriental poetry; Gorecki, Siemienski, Garczynski, Bielowski, Julius Slowacki, Groza, Krasinski, and numerous others. Novels were published in the earlier part of this century by Niemcewicz (*Jan Tenczynski*), Maria Czartoryska (*Malvina*, originally in French), Bernatowicz (*Nalecz*, *Pojata*), and Skarbek, and more recently by Grabowski, Czajkowski (*Wernyhora*, *Kirdzali*, *Czarniecki*), and especially Kraszewski. Dramas have been written by Skarbek, Kaminski, Fredro, Magnuszewski, and others; the best historical works, beside Lelewel, by Bandtke, Maciejowski, Narbutt, Eduard Raczynski, Plater, and Lukaszewicz; the most popular educational works by Clementina Tanska-Hoffmann; and philosophical works by Sniadecki, Trentowski, and Libelt. The most important works on Polish literature are by Mochnacki, Muczkowski, Bentkowski, Ossolinski, Chodynicki, Wiszniewski (*Historya literatury polskiej*, 7 vols., Cracow, 1840-'46), and Lukaszewicz (Posen, 1849).—The centres of Polish literary activity, and especially of periodical literature, are Warsaw, Wilna, Posen, Cracow, Lemberg, and Paris, the latter city as the principal seat of the Polish emigration. Warsaw, however, in spite of very severe restrictions on the press, has always maintained a decided preëminence over all its rivals, as the literary no less than political metropolis of Poland.

POLAR EXPEDITIONS. See ANTARCTIC RESEARCHES, ARCTIC DISCOVERY, and MACCLINTOCK, SIR FRANCIS LEOPOLD.

POLARIZATION OF LIGHT, a change that may be produced in the rays of light, such that they appear to have acquired different properties on different sides, and so that they are no longer like common light in being reflected or transmitted indifferently in all positions of the polished or transparent surfaces on which they may impinge. The subject includes double refraction, which is one of the chief means of producing polarization. The phenomena of polarized light are justly regarded as the most curious in the science of optics; but the subject has become so extensive and complex, that it can be presented fully only in the larger special treatises of optical science. See Sir D. Brewster's "Treatise on Optics" (new ed., London, 1853), and Pereira's "Lectures on Polarized Light" (London, 1854).—Common light, as that from a candle or gas flame, and in a degree that of the direct sunbeam, can, by properly presenting an opaque mirror in its course, be mainly reflected, and equally well up, down, to right or left. But a perfectly polarized beam, if reflected best up or down, *i. e.*, in a vertical plane, is totally extinguished if the mirror be then so turned as to throw it to right or left, *i. e.*, in the horizontal plane, and *vice versa*. The ray of light here behaves as if it were flattened, and accordingly is differently affected as it strikes flatwise or edgewise on the surface of a mirror or medium. There are several varieties or degrees of polarization, the names of which have been given with reference to the undulatory theory. (See LIGHT.) To account, by that theory, for the phenomena of polarization, a ray of common light must be considered as being propagated by vibrations that are transverse to the course of the ray, the particles of ether moving in curves that have the form of ellipses, and a great number of these ellipses being described at once or successively in all possible directions crossing the path of the ray. But by impingence of a ray so vibrating on a reflecting surface, or its passage through some medium, we can readily suppose the forces acting on the molecules to be resolved in some way, so that, first, all the varying elliptical movements shall be reduced to two sets of rectilinear movements, crossing each other, as well as the path of the ray, transversely, and hence vibrating in two planes at right angles to each other, when the common or heterogeneous ray is resolved into two rays, plane-polarized; or secondly, the light striking a reflecting surface may be partly absorbed or transmitted, and the part reflected may consist of elliptical movements of which the less axis has become 0, so that all have been brought into a single plane, when we have a single plane-polarized ray; or thirdly, the elliptical movements, though not rendered linear, may be brought to coincide in a given direction, giving partially polarized or elliptically polarized light; or fourthly, the resolution of the forces maintaining the vibration may be such that the axes of all the ellipses may be brought to coincide in direction, while the two axes in each become equal, when the light is circularly polarized. All the considerations from which these names are derived are thus extremely hypothetical; yet the conditions producing the various kinds of polarized light, and the results obtained with such light, are shown by mathematical analysis to correspond rigidly with these suppositions. Light may be very nearly or completely plane-polarized in 4 ways: 1, by double refraction; 2, by one reflection from a transparent body; 3, by several refractions through transparent surfaces; 4, by absorption or dispersion of part of the light. (1.) Light can emerge from a medium simply refracted or dispersed only when the medium is a gas or fluid, glass slowly and equally cooled, or a crystalline body of the monometric system, as the cube or the regular octahedron, &c., and this having the same temperature and density throughout its mass, and not exposed to pressure. But when a ray or beam of light passes through crystals of other forms, bone, horn, shell, hair, the crystalline lens of the eye, or elastic integument; or particular leaves, stalks, or seeds; or such artificial bodies as gums, resins, and jellies; or transparent bodies of varying density, owing to transient passage of heat, or to unequal temperature, or pressure; it will, in all these cases, save generally in some one direction of transmission, suffer a division into two rays. In the greater number of instances, both these will emerge, though in different places and directions; and the ray of light so affected is said to be doubly refracted. The substances effecting this change are said to be bi-refringent, or doubly refracting. This phenomenon, described by Bartholin in 1669, and first successfully studied by Huyghens in 1678, was first observed in crystallized carbonate of lime (Iceland spar). As the eye, receiving the divided ray, sees double images of objects observed through the crystal, the effect is conveniently witnessed by placing it over printed letters or other small objects, the crystal to be quite transparent, and better if an inch or more in thickness. The crystals showing no double refraction are such as have 3 equal, rectangular axes; and Sir D. Brewster believes that the absence of all apparent effect in these is owing to the fact of their having really 3 axes of no separation of the rays, the combined effect of which is to neutralize a tendency to separation in the directions intermediate. The ordinary crystal of Iceland spar is a rhombohedron, belonging to the hexagonal system, the crystals of which, as well as those of the dimetric system, have but one unequal axis of crystalline form. Now, singularly enough, if upon the crystal named we plane down and polish facets at right angles to this unequal axis, by taking off the two obtuse solid angles in which this axis terminates, we then find that any ray perpendicularly incident on either of these facets, so as to be transmitted in the course of the axis, or parallel with it, undergoes no separation, and, as we would expect, it is not refracted; while a ray falling obliquely on such facet, or falling in any manner on any other face of the crystal, is separated into two rays, generally both refracted, diverging more or less according to the direction and place of incidence, and emerging at different points. This result is termed double refraction of the light; the axis along which no separation occurs is called the optic axis. Any plane section containing this axis, called a principal section, gives a like result. In crystals of the kind now considered, one of the rays is refracted always according to the law of simple refraction (that of the sines), *i. e.*, it is in the plane of incidence, &c.; and if the light fall on an artificial face parallel with the optic axis, and so as to pass through the crystal in a plane at right angles to the axis (equatorial section), though there are two rays, they both obey the law of simple refraction. But in any other direction than one of the two now indicated, one of the rays is turned out of the plane of incidence, and at angles departing from those required by the law of the sines. This ray is therefore called the extraordinary ray; the other, the ordinary ray. In Iceland spar, tourmaline, &c., the former of these rays diverges more from the axis or perpendicular than the latter; its angle is greater, *i. e.*, its index of refraction is less, and crystals of this kind are termed negative. In quartz, ice, &c., the relation of the two rays is reversed, the path of the extraordinary ray being within, or nearer the perpendicular; and these crystals are termed positive. It will have been seen that in all cases an optic axis, also called an axis of double refraction, is not a fixed line through the crystal, but a fixed direction through it, and related to a line or lines about which the faces of the crystal are symmetrically placed. A large class of crystals, including the trimetric, have two chief axes of form, and accordingly two optic axes, or lines and directions in which a ray suffers no separation; while for all other incidences neither of the rays obeys the law of the sines; *i. e.*, both are extraordinary rays. These crystals are hence distinguished as bi-axal; those with one axis, as uni-axal. Among bi-axal crystals are mica, selenite, feldspar, &c. In rarer instances, 3 optic axes are found, or, as in analcime, there are several planes (not containing the same axes) of no refraction; in all such cases the results become extremely complex. Cubes of homogeneous glass become doubly refracting upon being unequally heated or pressed; and a laminated structure, traction, and electro-magnetism are prominent among the agencies inducing a like result. Now, if, by means presently to be indicated, we examine the two rays obtained in a case of double refraction, we find them both, and whatever the color of the light, completely polarized, and this always in planes at right angles to each other. A ray falling at any angle on glass has a portion reflected from the first surface, and, neglecting other particulars, a second portion transmitted through the glass. At any angle, both these portions are partially polarized; the most complete (maximum) polarization of the reflected ray occurs when the angle of incidence is 56° 45′; and at the same time the greatest polarization of the transmitted pencil possible by a gle plate takes place. Now, the first ray is id to be polarized in the plane of the incience, or in the plane of reflection, which is e same. That is, the plane of polarization e reflected light coincides with the plane of cidence; and with this corresponds the plane polarization of the ordinary ray in double fraction. But the transmitted ray on emerge is found polarized in a plane at right angles ith that of the incidence on the first surface, r with that of refraction (the two surfaces of e glass plate being supposed parallel); and e plane of polarization corresponds with that f the extraordinary ray. Unfortunately, however, the plane in which the vibrations of plane-olarized light are believed, from the latest esearches, to take place, varies in any case rom that now found by 90°; so that to the articulars already stated must be added this: he plane of vibration of plane-polarized light s always at right angles to that which is called he plane of its polarization. When the two rays emerging from a doubly refracting body are allowed to pass through a second, the principal sections of the two parallel, the rays are merely further separated; turned, so that the principal section of the one is perpendicular to that of the other, the ordinary becomes an extraordinary ray, and the reverse; in positions intermediate, both rays undergo separation anew, and 4 images are seen, save that in a single position all 4 images coalesce into one. Hence, a beam of light being passed, or bodies being seen through two such crystals, and one of them meanwhile turned, a succession of images appear, separating and reblending, during a half revolution, in the numbers and order, 2, 4, 2, 4, 1, &c. So, a ray polarized by reflection is perfectly reflected if impinging on a second mirror so that the perpendicular to the point is in the plane of polarization; but turn the mirror so that the perpendicular is at right angles to the plane of polarization, and the ray is totally extinguished; and in all circumstances where this occurs to polarized light striking a reflecting surface, perfect transmission occurs if a refracting medium be presented to it in the corresponding position, and vice versa. Hence, of any two polarizers, whether by double or ordinary refraction, or by reflection, either one may be used to impart polarity to a beam of common light; and the second then, properly placed to receive this beam, determines, by diminishing its brightness or extinguishing it in certain positions, that it had been polarized. Or, if certain light be known or suspected to be polarized, a crystal or mirror placed in its path, and turned, determines whether the light is polarized; and if so, shows by the positions in which the beam is made wholly or most nearly to disappear, in what plane polarization had occurred. Any contrivance capable of polarizing light is termed a polarizer; and any one capable of determining the condition of the light examined by it, an analyzer. Of course, any one of the former serves the latter purpose; though certain ones, as the mirror of blackened glass, a bundle of glass plates, or still better, a doubly refracting crystal properly prepared, are most convenient. The best of these is a tourmaline plate, or that known as Nicol's prism—simply an elongated prism of Iceland spar, cut into two by a section through an obtuse solid angle, and making an angle of 22° with the opposite obtuse solid edge, the terminal faces being ground to such an angle that, while they are parallel, one of them shall make an angle of 90° with the section. Then the two portions are reunited with Canada balsam, and the lateral faces blackened. In this prism the ordinary ray is totally reflected by the film of balsam, and absorbed by the blackened sides; the extraordinary ray passes through. A polarizer and an analyzer, with graduated arcs for reading degrees, and suitable connections, constitutes a polariscope; and by means of instruments of this kind most of the facts of polarization are ascertained, and application of its principles made. (2.) In respect to polarization by reflection, the general law arrived at by Brewster in 1814 is this: the angle, for any substance, at which maximum polarization occurs (called the polarizing angle), is that the tangent of which is equal to the index of refraction for that substance. This is true, whether the substance be transparent, or, for ordinary thicknesses, opaque; and the polarization decreases both ways from this angle of maximum. As a consequence, maximum polarization of reflected light always occurs when the sum of the angles of incidence and refraction equals 90°. Again, the different colors have different angles of maximum; so that polarization by reflection is never quite complete. The polarizing angle of glass for the mean ray is that above given; that of water, for the mean ray, 53° 11'. At other angles than the maximum, light is polarized to its maximum by repeated reflections. (3.) Transparent bodies transmit more light than they reflect; yet, in ordinary cases, for every angle the amount of polarization in the refracted equals that in the reflected beam. The effect is greatest at the polarizing angle; but even here the transmitted light is but partially polarized. By passing this light through a succession or bundle of plates, the polarization may be made complete. With 12 plates of crown glass, this occurs at 74°; with 24, at 60° 6', &c. (4.) Certain crystals, especially those of smoky or dark color, absorb a portion of the light, apparently one of the rays due to their double refraction, and transmit the other completely polarized. Of these, tourmaline is the best example. Light passed through one plate of this substance is almost completely extinguished by a second, only when the axes of the two are at right angles.—Beside the 4 methods now stated, there are some other actions capable of polarizing light, as that of the surfaces of some crystals. Elliptical polarization is especially found in the case of the metals; and it is feeble in degree. Ordinarily we see just as well by polarized as by common light; but there are circumstances in which a difference occurs. The crystalline lens of the eye being an analyzer, a person who has learned to detect them will discover in polarized light, from whatever source, an appearance of yellowish tufts or brushes crossed at the middle with violet (Haidinger's tufts, or *houppes*), which to other eyes are wholly undetected. Glare from water, glazed pictures, &c., consists largely of polarized light. Hence the water telescope containing a Nicol's prism, placed in a certain position, cuts off the polarized portion of the reflected light, and enables one to see the bottom of a shallow body of water, or fish beneath the surface; and an opera glass containing such prisms shows pictures in their true colors and without glistening, even when looked on obliquely. The same means has lately been proposed for enabling the eye to penetrate to greater distance into fog. If, between a polarizer and analyzer, a plate of selenite, mica, or almost any bi-refringent, of proper thinness, be introduced, one ray can be retarded, by difference of path, just so far as to interfere with the other on emerging, and the most beautiful colors are the result, which vary with the thickness of the film and the position of its axis. In this way, fine crystals of salicine, of bitartrate of potassa, and others, shavings of bone, &c., yield remarkable displays of changing color; and as these colors are strictly characteristic, or vary with the substances examined, a test of uncommon delicacy and accuracy is thus unexpectedly supplied, by which to determine, with the aid of the microscope, the nature of such substances as are capable of polarizing light, to detect adulterations in food, chemicals, &c. The change in the polarized ray in these cases has been named de-, or more properly di-polarization. These plates of many bi-refringent crystals exhibit each a characteristic set of colored rings, marked with a cross; the rings, as the plate is revolved, changing their colors to those complementary to them, and the crosses alternating from black to white. The differences in the dark cross of starch grains from various plants furnish a ready means of determining their source. A beam of common light is circularly polarized by rock crystal (quartz), and by many liquids, among which are most essential oils, and concentrated sirup of cane sugar. This condition is not readily detected by the ordinary analyzer, but by a peculiar polyhedron of glass, known as Fresnel's rhomb. In the bodies just named, it is replaced when the ray entering them is previously plane-polarized, by a rotation of the ray about its own axis, the amount of rotation being as the total thickness and the density of the medium. This phenomenon is called rotatory polarization; and it is detected by the ordinary forms of analyzer, as the Nicol's prism, the different colors being rotated in different degrees. Thus, in quartz, every $\frac{1}{25}$ inch in thickness shows the extreme red rotated 17° 30′, the middle green 27° 51′, the extreme violet 44° 5′. The rotatory power of a given depth and density of proper cane sirup being known, the rotation produced by any given sample becomes a measure of its density and purity, and hence of its value; and this is the principle of Soleil's saccharimeter. This rotation is from left to right; in different specimens of quartz it is right-handed or left-handed. Magnetic rotatory polarization is the same change, as induced or augmented by the action of an electro-magnet on a plane-polarized ray while being transmitted through certain media. Brewster and others have determined that the reflected light received at the earth's surface from the atmosphere is polarized, depending on the angular distance from the sun, save at certain changing neutral points. (See this subject in Johnston's "Physical Atlas.") Forbes, Melloni, and others have, by means of diathermanous media and the thermo-electric pile, shown the existence of both a polarization and di-polarization of heat; but no important results have yet been deduced. An application has been made of the principle of polarized light to the construction of a polarizing photometer, the object of which is to eliminate that part of the uncertainty in our judgment of the brilliancies of two lights viewed at the same time, which depends on differences of the colors of the lights; but the apparatus seems not to have come into use.—The discovery of polarization was first distinctly made by Malus so late as the year 1810. Its development since that time has been due to the labors of Young, Fresnel, Brewster, Biot, Arago, Sir John Herschel, and others.

POLE, Reginald, cardinal and archbishop of Canterbury, born at Stoverton castle, Staffordshire, in 1500, died in 1558. On his mother's side he was related to Henry VIII. Being destined for high positions in the church, he was sent when 7 years old to the Carthusian monastery of Shene, near Richmond in Surrey, and was graduated at Magdalen college, Oxford, in 1515. In 1517 he became prebendary of Salisbury, and in 1519 dean of Wimborne and Exeter. About 1520 he went to Padua to finish his studies. Returning to England in 1525, he was received with great favor by the king, and was much admired for his learning and abilities; but preferring to spend his time in study rather than in the gayeties of the court, he retired to Shene. He had been here about two years when Henry began to question the legality of his marriage with Catharine of Aragon; and Pole, foreseeing that there would be trouble, obtained from the king permission to visit Paris. Returning after a year's stay, his retirement was again disturbed by the determination of the king to throw off the pope's supremacy, and his desire to gain the approbation of his relative. As Pole refused his consent, to avoid the anger of Henry he passed over to the continent and dwelt successively at Avignon, Padua, and Venice. Meanwhile Henry had married Anne Boleyn, and wanted a defence of his title of head of the English church to be written by Dr. Sampson, bishop of Chichester. This was sent to Pole, who replied to it in a work entitled *Pro Unitate Ecclesiastica*, in which he compared the king to Nebuchadnezzar. Henry was so incensed with this treatise, that he withdrew from Pole his pension, deprived him of his preferments, and caused an act of attainder to be passed against him. Paul III., who was then pope, created him a cardinal, and sent him as nuncio to France and Flanders, and afterward as legate to Viterbo. Here he remained until the council of Trent, which he attended in the capacity of a papal legate, and is there said to have maintained the doctrine of justification by faith. Although suspected on this account of a leaning toward Protestantism, he was nevertheless employed by Paul in the affairs of the papal court, and upon the death of that pontiff came near being chosen his successor. Upon the accession of the new pope, he retired to the convent of Maguzano near Verona, and there remained until called to England by Queen Mary. He landed at Dover, Nov. 20, 1554, in the character of papal legate, and was received with great honor by the court. He was made archbishop of Canterbury after the burning of Cranmer, and was also elected chancellor of Oxford and subsequently of Cambridge. In the cruel measures which were taken at that time for the extirpation of Protestantism, it has been a matter of debate how far the primate was censurable; but the weight of evidence seems to favor the conclusion that he was inclined rather to lenient than to harsh proceedings. He died 16 hours after the death of the queen. His life was written by T. Phillips (2 vols., 1767).

POLECAT (*putorius communis*, Cuv.), a well known animal of the weasel family, spread over Europe and temperate Asia. It is about 16 inches long, the tail 6 inches additional, and 6 or 7 inches high; the general color is dark brown, fading into yellowish below, the legs and tail black, and the face whitish with a brown mask across the region of the eyes; the colors vary considerably. The form is elongated, the head short and rounded, the teeth the same as in the ferret, the feet 5-toed with sharp claws, the mammæ 4 and ventral, and the fur soft and thick. It is a very active animal, pursuing living prey upon the ground, and rarely ascending trees; very sanguinary by nature, its size limits its depredations to small animals, such as domestic fowls, ground birds, squirrels, rabbits, and other rodents; it is strictly nocturnal in its habits, remaining concealed during the day in some outbuilding on the farm, as it generally lives in the neighborhood of man, and committing its havoc at night in the hen roost and dove cot; it is destroyed by the farmer when possible, but it is so wary as generally to escape traps. When alarmed or irritated, it emits a very disagreeable odor in the secretion of the anal glands, which attaches itself even to the fur, preventing that use of it to which its fineness entitles it. The female generally makes her nest in a rabbit burrow, having previously killed or driven away the rabbit. Its habits and manner of killing its prey are the same as in the ferret. The common fur called fitch is that of the polecat, one of whose popular names is fitchet.

POLEMO. I. A Grecian philosopher, born in Athens about 340 B. C., died about 272. In his youth he gave himself up to sensuality; but chancing one day, when half intoxicated, to enter the academy while Xenocrates was discoursing upon temperance, he was so moved by the words of the teacher that he became one of his disciples, and went to the other extreme of rigid and austere temperance. He succeeded to the chair of Xenocrates, and was the teacher of Arcesilas, Crates, and Zeno. II. A Grecian geographer, whose birthplace is uncertain, flourished in the early part of the 2d century B. C. He wrote a "Voyage round the World," from Pontus to Carthage, and polemical works against Timæus and Eratosthenes. An edition of his fragments by Preller was published at Leipsic in 1838. III. A king of Pontus, died after A. D. 2. He was originally of Caria or Phrygia, and was the son of Zeno the rhetorician. He obtained his kingdom from Mark Antony, whom he served efficiently in the war against Parthia. He was made prisoner, but obtained his liberty at the time when the civil war broke out between Octavius and Antony, and immediately marched his army to the assistance of the latter. The battle of Actium ended the struggle, and Polemo was easily reconciled to Octavius, who admired his fidelity, confirmed him in his sovereignty, and added to his realm all the territory upon the Bosporus. In a war against the Aspurgians, a barbarian tribe, he was made prisoner and put to death. IV. Son of the preceding. His mother Pythodoris held the sovereignty after the death of Polemo I., her son assisting her in the administration; and upon her death (A. D. 39) he was recognized by Caligula. Three years later the emperor Claudius ceded Cilicia to him in exchange for the Cimmerian Bosporus, which was given to a descendant of Mithridates. Polemo II. embraced Judaism in order to espouse Berenice, famous for her amour with Titus; but that princess having left him, he returned to his former faith. He abdicated during the reign of Nero.

POLEVOY, NICOLAI ALEKSEEVITCH, a Russian author, born in Irkootsk, Siberia, June 22, 1796, died in St. Petersburg, Feb. 22, 1846. He was the son of a manufacturer and brandy distiller, was educated at home, and at a very early age wrote plays. "At last," says he in his autobiography, "I became my father's walking dictionary in geography and history, for my memory at that time was such as I have never met with in anybody else. To learn by heart a whole tragedy cost me nothing. In a word, if I must describe my mental progress up to the year 1811, it was this: I had read about a thousand volumes of all kinds and sorts, and remembered all that I read, from the verses of Karamsin and the articles in the 'European Messenger' to the chronological tables and the Bible, from which I could repeat whole chapters by heart. I was known in the town of Irkootsk as 'the wonderful boy,' with whom the governor himself used to converse, and the director of the grammar school to dispute as with a learned man." Having while still young removed to Moscow, he was forced to flee on the approach of the French army. Returning several years afterward, he established a newspaper called the "Moscow Telegraph," which inaugurated a new era in Russian literary criticism, but was finally suppressed on account of its liberal tendencies. In 1838 Polevoy went to St. Petersburg, where he spent the remainder of his life, writing essays, romances, translations, tragedies, comedies, and farces. His incessant labor gradually broke down his constitution, while the rapidity with which he produced his works had the same effect upon his fame. The best of his dramas are "Parasha, the Siberian Girl," the author's favorite; the "Grandfather of the Russian Fleet;" and a translation of Hamlet. He wrote the "Life of Suwaroff," one of the most popular books in Russia, the "Life of Peter the Great," and a "Life of the Emperor Napoleon," which extended no further than the burning of Moscow, but was completed by the author's brother. He also announced a "History of the Russian People," to be finished in 62 volumes, but of these 6 only appeared.—His brother, Xenophon Alexeievitch, after having been for many years a bookseller at Moscow, is now living at St. Petersburg. He has written several works of considerable literary value, one of which is the novel of "Michael Vasilevitch Lomonosoff" (2 vols., Moscow, 1836).

POLI, Giuseppe Xaverio, an Italian naturalist, born in Molfetta, in the kingdom of Naples, in 1746, died in 1825. He entered the army, and was appointed by Ferdinand I. in 1776 professor of military geography at Naples, was soon after commissioned to visit the principal military schools of Europe, became a fellow of the royal society of England, and after his return was made professor of experimental philosophy and director of the military academy at Naples. Poli was distinguished as a comparative anatomist and physiologist, but particularly for his knowledge of the character and habits of testacean mollusks, in which department he made a large collection, and published the results of his investigations in a finely illustrated work entitled *Testacea Utriusque Siciliæ* (2 vols. fol., Parma, 1792–'5; vol. iii., 1826). His descriptions are mostly very accurate, and he discovered many new genera and species. To him is due the discovery of the nervous system of the testacea.

POLICE (Gr. πολιτεια, government), a judicial and executive system and an organized civil force for the preservation of order and the enforcement of the laws. There are traces of a police, or something analogous to it, in Athens, Corinth, and Ephesus. In Rome the duties of the policeman seem to have been shared by several classes of officials; the lictor arrested criminals and conducted them into court, and the inspectors, subprefects, and other officers, either personally or by their subordinates, performed most of the civil duties now devolving on the police. In despotic governments the police have exercised important and often oppressive functions. Its beneficent action in sanitary matters, in preventing and detecting frauds, larcenies, and petty crimes, and in promoting the reformation of juvenile offenders, is of recent date even in those countries where the system has been longest and most completely organized.—The police system in France, though not so oppressive, except for some comparatively brief periods, as in some of the other countries of Europe, is of considerable antiquity. Previous to the middle of the 15th century, the provost of Paris and his lieutenants, civil and criminal, were charged with maintaining the peace of the city, and with the suppression of vagrancy. About 1446 or 1447 the city was divided into 16 districts, over each of which a commissary of police presided, having under him a certain number of sergeants, the whole being under the control of the provost, to whom in 1448 Charles VII. committed a general jurisdiction over the vagrants and malefactors of the kingdom. About 1520 Francis I. deprived the provost of the city of his extensive jurisdiction, and created a provost marshal (*prévôt de maréchaux*) for the city and district of Paris, who was authorized to apprehend and punish vagrants and disorderly persons, without appeal. Under his orders were placed 30 constables, and the number of commissaries and sergeants of police was doubled. But even with this increase of force there were as late as 1560 only 500 men of all ranks in the Parisian police. The superintendence of the markets, weights and measures, and cesspools, the cleansing of the streets, the inspection of buildings, and the prohibition of noxious trades, were all subjects of legislation in France at a very early period, statutes having been passed relative to them at various dates between 1350 and 1560. The importance of having them all included in one system of surveillance was not, however, understood, and each had its own inspectors, amenable to no common head. In 1577 the privilege of electing their own police magistrates was granted to the inhabitants of each of the districts of the city. Under Louis XIV. the police attained its highest measure of perfection as a repressive force. A universal espionage was established, and the slightest intimation of restiveness under the yoke of oppression, or the smallest departure from the monarch's views of orthodoxy, was visited with summary arrest and punishment. In its more humane and protective functions it was less successful. Under the reign of Louis XV. it partook of the general decay and demoralization which had infected the other departments of government, was the base pander to the depraved appetites of the monarch, and furnished the ready means of extortion and oppression of those who had become obnoxious to his favorites. The national convention in 1794 reorganized the police and defined its duties. These duties comprised almost every department of administrative government, including, among other matters, the securing of the safety of traffic; the repair of dangerous structures; the superintendence of the cleansing and lighting of the city; the removal of public nuisances; the repression and punishment of all offences against the public peace; the maintenance of good order in and supervision of all public gatherings, festivities, and places of public amusement and resort; the inspection of weights, measures, and food; precautions against accidents, casualties, and epidemics, and measures in mitigation of them if they occurred; the delivery of passports, residence licenses, &c., and the repression of beggary and vagrancy; the supervision of drinking and gaming houses, and of prostitutes; the dispersion of crowds; the police of religious worship and of printing and bookselling; the oversight of theatres, powder mills, saltpetre works, and storehouses of arms; the pursuit of deserters and escaped criminals; the care of the highways, of the public health, and of fires, inundations, and accidents; the superintendence of the exchanges of commerce, of the taxes, of the provision markets, and of prohibited wares; and the protection of public monuments. To these multifarious duties were added, soon after, the regulation of the fees of health officers and veterinary surgeons, the removal of sick persons and corpses, the recovery of drowned persons, and the care of the public pounds. During the administration of Napoleon I. the city police of Paris attained a high degree of efficiency. The ablest of the prefects of police of that period, Gisquet, has written the memoirs of his times. Under Louis Philippe, the number of the regular policemen, *sergents de ville*, had risen in 1847 to 1,800. It was during his administration that the present system of police respecting prostitution, which had been for many years under police surveillance, was adopted. The Parisian police is now metropolitan, comprising the whole department of the Seine, the districts of St. Cloud, Sèvres, and Meudon in Seine-et-Oise, and the market of Poissy. It is in charge of a prefect, who is under the authority of the minister of the interior. He is president of a council of health of 20 members, all physicians, surgeons, or chemists, which has charge of all sanitary matters, and meets fortnightly. Beside this council, there are 11 bureaus, in 3 divisions, each under a competent head, and each in charge of a class of police regulations. There is also a commissary of police in each of the 80 quarters of Paris.—Beside the local police of Paris, which under some of the Bourbon kings assumed or was endowed with national jurisdiction, there has been for two centuries a system of national police in France, whose functions have been mainly detective and repressive. The espionage of suspected strangers visiting the country, or of persons believed to be disaffected or to entertain designs against the government, the correspondence of those regarded as hostile to the reigning authority, and other similar subjects, have been the duties intrusted to it. Until 1796 this national police had been under the direction of the ministry of the home department; but at that time the directory created a ministry of police, and after Cochon, Lenoir de la Roche, and Sotin had each held the post of minister for a brief period, Fouché received the appointment in 1799, and held it with brief intermissions till Sept. 1815. Decazes, the successor of Fouché, retained the office till 1818, when it was abolished as an independent department.—In England, from the time of the Saxon kings, there had existed an organization of a partially voluntary character for the repression of crime, the arrest of criminals, and the maintenance of good order. The population was divided into hundreds, and these into tithings or companies of 10 freeholders with their families. The principal man of the hundred was the justice of the peace, or local magistrate, for the trial of small causes, and the head man of the tithing was responsible for good order and the arrest of criminals in his limited district. As the population increased, however, and criminals grew more daring and ferocious, it was found that these voluntary officers did not like to arrest or convict a known and desperate offender, lest, as was often the case, he should subsequently wreak his vengeance on them. The high sheriff of the county, his deputies, and the constables appointed by the parishes, were eventually substituted for the voluntary officers of the earlier period; but while they answered their purpose tolerably well in the rural districts, they were neither numerous nor efficient enough to repress crime in London. As late as 1751, Henry Fielding, the novelist, then magistrate at Bow street, the only court for police offences at that time outside the city proper, in an "Inquiry into the Causes of the recent Increase of Robberies," stated as matter of public notoriety that the streets of London were not safe for citizens after nightfall, and that highway robberies, murders, and other flagrant crimes were of common occurrence, and their perpetrators were seldom or never detected or arrested. He suggested a paid police, under the orders of the acting magistrate at Bow street. In 1753 such a force, of very moderate extent, was established in accordance with an act passed that year; but such was the fear of the people lest this measure should lead to encroachment upon their liberties, that a violent opposition was raised to it, and it was soon repealed. In 1792 an act was passed for the increase of the police courts, the employment of salaried magistrates, and the enlargement of their jurisdiction. Under this act, 8 police offices or courts were established, and the magistrates received a salary of £400 each, which was afterward raised to £600. In 1800 there were 6 police constables attached to each of the metropolitan police offices, or 48 in all; 60 other constables, under the charge of the chief magistrate at Bow street, patrolled the metropolitan roads; the Thames police establishment, organized in 1798, consisted of 41 officers; the city of London employed and paid 40 more; and beside these there were 868 parish officers serving without pay. The night watch and patrol consisted of 2,044 men for the entire metropolitan district, of whom 808 were in the city of London. The greater part of these men were aged, feeble, infirm, and many of them half starved; their compensation ranged from 17 to 36 cents per night; and they were under the control of more than 70 different boards of officers. This state of things continued, with little amelioration, till 1829, when Sir Robert Peel's "act for improving the police in and near the metropolis" was passed. This act established an effective constabulary force under two commissioners, but left several petty detached bodies of peace officers within the district. In 1839 it was modified by an act consolidating the entire constabulary force of the metropolis, the city of London excepted, which still maintains a small independent force, 608 men in 1859. By this act also the entire executive duties of police were intrusted to the commissioners; their sphere of action in regard to all matters properly belonging to police was greatly enlarged; the police courts were assimilated to the other courts of justice, and a single magistrate was empowered to decide, without appeal, questions involving sums of money not exceeding 40 shillings, as well as those cases of offence against the person so constantly recurring in a police court; and the boundaries of the police districts were changed to adapt them the better to the growth of the metropolis. In 1856 the joint commissioners were superseded by one commissioner, whose salary was fixed at £1,500, and two assistant commissioners were appointed, at a salary of £800 each.—The rural police or county constabulary force in England is of recent origin. The difficulty of arresting criminals and preventing crime, especially among juvenile offenders, led to its organization. In 1840 parliament passed an act permitting any county, or part of a county, to organize a police force on a plan somewhat similar to that of the metropolitan police. The county of Essex availed itself of the permission the same year; and between 1840 and 1858, 18 English and 4 Welsh counties had adopted it for the whole of each county, and 7 others for parts. In 1856 the "act to render more effectual the police in counties and boroughs" was passed, and there is now a county constabulary force in every county, which reports annually to the secretary of state. The effect of the organization of this force has been greatly to diminish the amount of crime, especially among the young, who are now promptly committed to reformatories, and to render property safer and the administration of justice more uniform. The expenditure for the county constabulary in 1859 was £991,555, and the total number of policemen was 13,309.—In Scotland the organization of an efficient police in the large towns dates from 1834, and has been materially modified by subsequent laws. The rural police has been organized under the law of 1857, which is similar in its provisions to the English law of 1856.—In Ireland, until 1814, the police was in a perfectly chaotic state. The law passed that year led to improvements in detail, but did not remove the management of the force nor the functions of the inferior magistracy from partisan control, by which they were often made the instruments of outrageous abuses. The act of 1836, and its subsequent modifications in 1848 and 1857, have greatly improved it. It is of a quasi military character, being well armed and occupying barracks. In 1858 the number of members was 12,067, and the cost £668,700. The city of Dublin and its vicinity has also a metropolitan police, with a force of 1,087 men; its cost in 1858 was £77,027.—In the United States, the provisions for the repression of crime and the detection and arrest of criminals were copied from those of Great Britain. Each county had its sheriff and deputies, and, where there were town organizations, each town its constables. Justices of the peace, of whom there was a considerable number in each county, and often in each town, appointed by the legislature, or of late elected by the people of the town or county, had absolute jurisdiction in petty civil and criminal cases, and power to bind the accused over to a higher court in any case. In the larger towns, the danger to property from fires, burglaries, &c., in the night time, led to the appointment of watchmen, who, like those of London, were often aged and infirm men, few, and poorly paid. The organization of a day police is of recent date even in the cities of New York, Philadelphia, Baltimore, Boston, New Orleans, and Cincinnati. At first the police force was municipal, confined to the chartered limits of the city, and appointed by the mayor and council. To such a plan there were found to be two serious objections, viz.: that evil doers would escape beyond the city limits, and thus evade their jurisdiction, and that the appointment and control of the police was made a partisan matter. In 1857 the legislature of New York passed an act for the establishment of a metropolitan police force, which should possess constabulary powers in the counties of New York, Kings, Westchester, and Richmond, and in the towns of Jamaica, Newtown, and Flushing, in the county of Queens. This force was to be under the control of 7 commissioners, including the mayors of New York and Brooklyn *ex officiis*. In 1860 this act was modified and the number of commissioners reduced to 3, who were to be appointed by the governor, and to serve 5 years. The duties of the policemen were also enlarged by this act, and now include most though not all of those of the police force of London and Paris. The following tables give the comparative statistics of the police of London and New York, with the force and cost of that of Paris:

TABLE I.—NUMBER, GRADE, AND PAY OF POLICE FORCE, AND TOTAL EXPENDITURE.

Metropolitan district.	Commissioners.	Pay.	Superintendents.	Pay.	Inspectors.	Pay.	Captains.	Pay.	Sergeants.*	Pay.	Patrolmen.*	Pay.	Total force.	Total pay of force.	Total expenditure for police service.
London, 1860....	1 at 2 at	$7,260 8,872	22	$2,130 to 963	189	$968 to 897	..	..	10 at 691 at	$529 208	5,708	$378 to 289	6,638	$1,705,696	$2,878,508
Paris, 1859 †	8 at	2,000 1,600 1,000	25	800	85	1,000 to 600	57	$860	319	320	3,950	300	4,298	1,600,000	1,669,280
New York, 1860.	3 at	8,000	1	5,000	1 at 3 at	2,400 2,000	32	1,200	146	900	1,600	800	1,786	1,276,577	1,832,977

TABLE II.—RESULTS: LONDON, 1856; NEW YORK, 1860.

Metropolitan district.	Population.	Whole number of arrests.	Males.	Females.	Under 15.	Under 20.	Offences against the person.	Offences ag'st property.	Vagrants.	Sanitary cases.	Natives.	Foreigners.	Percentage of offences ag'st the person to all offences.	Percentage of offences ag'st property.	Percentage of vagrants.
London.......	2,500,000	73,240	..	..	..	..	10,480	24,749	2,592	1,945	..	..	14.8	83.8	8.5
New York....	1,400,000	81,143	56,975	24,168	2,886	10,585	61,900	18,975	5,268	12,093	17,811	63,832	76.2	17.9	6.49

Though strongly opposed at first, the change of system in New York has proved beneficial, and is generally approved. Baltimore and Philadelphia have adopted a similar one, and the change is about to be made in Boston. The police courts in New York (and the same is true, we believe, in the other cities which have adopted the system) are not a part of the metropolitan police organization. The pay of both officers and men is higher than that of the London or Paris metropolitan police, that of the men being more than double; so that in London, with a force nearly 4 times as large (the proportion being 1 to 324 of the population, against 1 to 784), the cost of the police is less than twice as much as in New York; while with Paris (pop. 1,324,346; proportion, 1 to 803) the comparison is nearly the same.

POLIGNAC, JULES AUGUSTE ARMAND MARIE, prince de, a French statesman, born in Paris, May 14, 1780, died at St. Germain-en-Laye, March 29, 1847. His parents being obliged to leave France at the time of the revolution, he went first to Russia, and then to England as aid of the count d'Artois (afterward Charles X.), and in Dec. 1803 returned to France, being concerned in the conspiracy of Cadoudal and Pichegru. When the plot was discovered, his brother Armand, who was also engaged in it, was sentenced to death, and he himself to 2 years' imprisonment. Armand's life was spared, but both were retained in captivity until 1814, when they escaped and rejoined the count d'Artois. After the second restoration, Jules was made a peer of France, but refused to take the constitutional oath on account of religious scruples, until these were relieved by the pope, who also made him a Roman prince. In 1816 he married Miss Campbell, a Scottish heiress. He was minister to London from 1823 to 1829, when he was recalled by Charles X., and in August became the head of the new ministry, with the portfolio of minister of foreign affairs. He was the representative of the ultramontane party in the state, and was looked upon with great disfavor by the friends of constitutional liberty throughout France. The growing difference between the ministry and the chambers, and the arbitrary measures of the court, after a few months led to the revolution by which Charles was deprived of his throne. Polignac fled, but was arrested at Granville, Aug. 15, 1830, in the disguise of a valet, was tried, found guilty, sentenced to imprisonment for life, and confined in the fortress of Ham until 1836, when he was released, lived for some time in England, and finally returned to France. During his imprisonment he wrote a work entitled *Considérations politiques* (Paris, 1832).

POLIGNAC, MELCHIOR DE, a French cardinal and statesman, great uncle of the preceding, born in Puy, Oct. 11, 1661, died Nov. 20, 1741. He was sent as ambassador to Poland by Louis XIV., and after the death of John Sobieski in 1696 contrived to have the prince of Conti elected king; but this choice not being accepted by the nation, who placed the crown on the head of Frederic Augustus, elector of Saxony, Polignac fell into disgrace and was recalled. Banished to his abbacy of Bonport, he employed his time in refuting Lucretius in a Latin poem entitled *Anti-Lucretius, sive de Deo et Natura* (2 vols. 8vo., 1745). He returned to court in 1702, was made auditor of the rota at Rome in 1706, and minister plenipotentiary to Holland in 1710, and was a commissioner on the part of France to negotiate the treaty of Utrecht in 1713. On his return from the last embassy he was created cardinal. During the regency he attached himself to the party of the legitimists, and was again banished until 1721. From 1724 to 1732 he was the French minister at Rome, and in 1726 obtained the archbishopric of Auch. He succeeded Bossuet in the French academy in 1704.

* These officers in London also receive their clothing, and a ton of coal yearly if married, or ½ of a ton if single.

† The titles of the officials are of course different in Paris, but we have arranged them as far as possible under corresponding grades.

POLITIANUS, ANGELUS. See POLIZIANO.

POLITICAL ECONOMY (Gr. οικος, a house, and νομος, a law), properly, an exposition of the measures necessary for directing the movements of society so that man may act in harmony with those laws which control him in his efforts to improve his condition. Great confusion exists not only in the definition of political economy, but in the various expressions made use of in treating of the subject, and even in settling upon some general understanding of its scope. By some writers it has been treated as a science, by others as an art, and Sir James Steuart speaks of it as a combination of the two. Mr. Senior considers it "the science which treats of the nature, the production, and the distribution of wealth." Archbishop Whately would give it the name of "catallactics, or the science of exchanges." Mr. McCulloch considers it "the science of the laws which regulate the production of those material products which have exchangeable value, and which are either necessary, useful, or agreeable to man." M. Storch says it "is the science of the natural laws which determine the prosperity of nations, that is to say, their wealth and civilization." M. Sismondi considers "the physical welfare of man, so far as it can be the work of government, as the object of political economy." M. Say defines it as "the economy of society; a science combining the results of our observations on the nature and functions of the different parts of the social body." The progress thus far made in political economy has been slow and uncertain, and there is in its entire range hardly a doctrine or even the definition of an important word which is universally or even generally accepted beyond dispute. In 1844 Mr. De Quincey was forced to acknowledge that it did not advance, and that from the year 1817 it had "on the whole been stationary;" and he further adds: "Nothing can be postulated, nothing demonstrated, for anarchy even as to the earliest principles is predominant." M. Rossi says: "Notwithstanding the pretensions so frequently put forward by politicians and economists, some of the most interesting portions of the sciences they profess are still imperfectly understood;" while "the important art of applying them to the affairs of mankind, so as to produce the greatest amount of permanent good, has made but little progress and is hardly indeed in its infancy." Amid all their discords and disagreements, it is possible to divide political economists under two general heads: those who treat the subject as a deductive science, "in which all the general propositions are in the strictest sense of the word hypothetical;" and those who treat it by the inductive or Baconian method. Of the first named school are all the English economists and most of those of continental Europe who have acquired any reputation. As the representatives of the last, Mr. Henry C. Carey and his followers are most prominent. —The earliest treatise on an economic subject is believed to be "The Eryxias, or About Wealth," erroneously attributed to Æschines Socraticus, one of the disciples of Socrates, and assigned to the date of 427 B. C. "Plato," says Say, "has with tolerable fidelity ('Republic,' book ii.) sketched the effects of the separation of social employments, but solely with a view to point out man's social character, and the necessity he was in, from his multifarious wants, of uniting in extensive societies, in which each individual might be exclusively occupied with one species of production. It is an entirely political view, from which no other consequence can be drawn." To Aristotle, however, is due the honor of being the founder of political economy. His three treatises—"Ethics," which treats of the regulation of the individual man; "Politics," of the relation of man toward others in a social capacity, both private and public, the family and the state; and "Economics," of the relation of man toward property—constitute in a measure a connected work, each being dependent on and interwoven with the others. The expression political economy was first used by Aristotle, and is to be found in the "Economics," book ii. chap. i. He lays down the dogma that the bounty of nature is the only true source of wealth, and he holds in great abhorrence trading and usury, which latter, he says, "is most reasonably detested, as the increase of our fortune arises from the money itself, and not by employing it to the purposes for which it was intended." But little attention was paid to economic studies for many centuries after the time of Aristotle. The ancients regarded industrial occupation of any kind as degrading and unworthy of freemen. Agriculture was looked upon with much more favor than any other employment involving labor, but even farm labor was performed almost entirely by slaves belonging to and employed by the landlords. The light in which trade was regarded by the Romans may be gathered from Cicero, who in his "Offices" says: "The gains of merchants, as well as of all who live by labor and not skill, are mean and illiberal. The very merchandise is a badge of their slavery."—During the middle ages, and for some centuries thereafter, no advance was made either in commercial adventure or in letters; but "the fortunate enterprises of the Portuguese and Spaniards during the 15th century, the active industry of Venice, Genoa, Florence, Pisa, the provinces of Flanders, and the free cities of Germany, about the same period, gradually directed the attention of some philosophers to the theory of wealth." These investigations originated in Italy. "As far back as the 16th century," adds Say, "Botero had been engaged in investigating the *real* sources of public prosperity." The earliest general treatise on this subject in modern times, and the first bearing the title of political economy, is the *Traité de l'économie politique*, by Antoine de Montchrétien (4to., Rouen, 1615). This work treats of the utility of mechanic arts and the regulation of manufactures, employment of men, the trades most important to communities, commerce, transportation, money, &c. In 1613 Antonio Serra published in Naples a volume on the causes which tend to aid an accumulation of the precious metals in those countries which do not produce them; and in 1618 Gian Donato Turbolo published in the same city a treatise on the money of the country. About this time treatises on commerce and the prohibitive system were published by Duarte Gomez (Lisbon, 1622) and Juan de Castañares (1626).—The attention of the earliest English writers on political economy was directed to foreign trade. They saw that it was desirable to have a metallic currency suited to the wants of the business of their country, and while advocating the extension of foreign commerce, they recommended the adoption of such measures as would cause gold and silver to flow into the country, and not out. The policy advocated by this school is known to economists as the mercantile system. It was supported among others by Misselden ("Circle of Commerce," 1623), and by Mun ("England's Treasure by Forraign Trade, or the Balance of our Forraign Trade is the Rule of our Treasure"). The last named treatise, though not published until 1664, after the author's death, was probably written as early as 1635-'40. In 1668 appeared the first edition of "A New Discourse of Trade," by Sir Josiah Child. Its author is usually classed among the mercantile school, but he did not regard a direct examination of the comparative amount of imports and exports, or even the movements of the precious metals, as a proper test of the advantages or disadvantages of a foreign trade; but he rather looked to its increase or decrease as presenting the most tangible evidence. He advocated reducing the rate of interest from 6 to 4 per cent., believing it to be the *causa causans*, as he expressed it, and that it would greatly facilitate business. He recommended "the prevention of the exportation of our wool, and encouraging our woollen manufactures," and that in Ireland the "linen rather than the woollen manufacture be set up." Further, that the trade of those countries "that vend most of our manufactures, or supply us with materials to be further manufactured in England," be most encouraged. In 1677 Andrew Yarranton published "England's Improvement by Sea and Land; to outdo the Dutch without Fighting, to pay Debts without Moneys, to set at Work the Poor of England with the Growth of our own Lands," &c. The means by which he designed to advance the prosperity and power of England were the introduction of a general system of banking, thus furnishing "the great sinews of trade, the credit thereof making paper go in trade equal with ready money," a registry of real estate to facilitate its transfer and mortgage, the improvement and development of the production and trade in linen, woollen goods, and iron, the introduction of canals and the improvement of rivers and harbors, with a view to facilitating internal trade and intercourse. He held that a country desiring to be rich, powerful, and happy, must introduce a diversified industry; and he recognized the necessary means for bringing about its development. "Above all," says Patrick Edward Dove, who regards him as the founder of English political economy, "we must note his prospective sagacity, for he points out in detail the very course that England has pursued, and the very elements that were to contribute to her commercial superiority."—A most important era in the history of political economy, as well as of industrial development, was the year 1662, when Louis XIV. placed Colbert in the position of comptroller-general of the finances of France. Of him it has been remarked by a distinguished French economist: "He is the only minister of state who has constructed a system complete and connected in all its parts, and to the immortal honor of his name be it said, he carried it out in despite of every obstacle which was thrown in his way." He reduced the national finances to system and order, and instituted a complete plan of checks and balances; reformed abuses in this department, and punished those who had been guilty of them; increased the revenues of the state, while at the same time he decreased the burdens of the people; provided for economical expenditures, and abolished many of the internal taxes; developed agriculture, manufactures, the arts, and the sciences; improved roads and rivers, built canals, and by every means fostered and increased the internal commerce of the country. By some writers the protective features of his tariff laws of 1664 and 1667 have been condemned; but on the other hand we are assured that for several years before his administration "France swarmed with vagabonds and mendicants," and had reached "the most profound depth of commercial depression," and that under the laws of which he was the author she rose to "a point of wealth and industry far beyond any she had ever reached since the foundation of the monarchy;" and even M. Say says: "It is not true that Colbert ruined France," but that, "on the contrary, France under Colbert's administration emerged from the distress in which two regencies and a weak reign had involved her."—The various restrictions upon trade, especially upon the importation of manufactured goods, and the export of the raw materials used in manufactures, at this time, and even later, and especially in England, were of a very onerous character. The penalties for the infringement of the laws were in many cases cruel and even barbarous. This system, with the policy pursued under it, was attacked by various writers. Among the earliest and ablest of these may be mentioned Sir Dudley North, who published "Discourses on Trade" (4to., London, 1691). Among the doctrines held by him as fundamental were: "That the whole world as to trade is but as one nation; that money is a merchandise whereof there may be a glut as well as scarcity, and that even to an inconvenience; that a people cannot want money to serve the ordinary dealing, and more than enough they will not have; and that money exported in trade is an increase to the wealth of a nation." Sir William Petty, in "Quantulumcunque, or a Tract concerning Money," had in 1682 attacked the theory of "the balance of trade;" and there were at a subsequent day many champions on both sides of this vexed question; among others Dr. Davenant (1695–1712), who espoused the so called mercantile theory, and Sir Matthew Decker (1743–'4) and Joseph Harris (1757–'8), who opposed it. In 1698 appeared in London "Historical and Political Essays, or Discourses on several Subjects," including money, government, &c., by John Locke, in which he for the first time promulgated some of the favorite theories in regard to money now held by European economists.—In 1758 there appeared at Versailles the *Tableau économique, et maximes générales du gouvernement économique*, by François Quesnay, followed by *Théorie de l'impôt*, by the elder Mirabeau (1760), *La philosophie rurale*, also by Mirabeau (1763), and various other works by Quesnay and his disciples, expounding the physiocratic or agricultural system of economy. The physiocratists held that the earth was the sole producer of wealth, and divided the industrial members of society into 3 classes: 1, the proprietors of the land; 2, the cultivators, consisting of farmers and agricultural laborers, whom they regarded as a productive class; 3, the mechanics, manufacturers, and merchants, whom they styled the unproductive class. That portion of his income which the landlord laid out in the improvement of his land they characterized as productive expenses; and in so far as the landlord by these expenditures aided the farmer in increasing the amount of his produce, the landlord became one of the productive class. They maintained that the labor of mechanics, manufacturers, and artisans was unproductive, because it merely replaced the stock which employed them, together with the ordinary profits of that stock; and that mercantile stock was unproductive because it merely continued the existence of its own value. They admitted that mechanics, manufacturers, and merchants might augment the revenue and wealth of society, but that it could only be accomplished by parsimony or privation. They believed that the most perfect freedom of trade with all nations was the great desideratum in agriculture. Dissenting entirely from the central idea of this school and its logical deductions, Adam Smith, however, in 1776, expressed the opinion that "with all its imperfections it is, perhaps, the nearest approximation to the truth that has yet been published upon the subject of political economy." Among the most eminent of the physiocratists was Turgot, afterward comptroller-general of finances, who early embraced the views of Quesnay, and in 1771 published *Réflexions sur la formation et la distribution des richesses*, the ablest of the treatises of this school. "In 1764," says Say, "Genovesi commenced a public course of lectures on political economy from the chair founded by the care of the highly esteemed and learned Intieri. In consequence of his example, other professorships were afterward established at Milan, and more recently in most of the universities in Germany and Russia."—Among the contributions to political economy up to the end of the 18th century, none evince greater reasoning power than the "Political Essays" of David Hume, which appeared in 1752. Among those essays which may be mentioned as coming within the limit of political economy, are "Commerce," "Refinements in the Arts," "Money," "Interest," "The Balance of Trade," "The Jealousy of Trade," "Taxes," and "Public Credit." According to these essays, every thing in the world is purchased by labor, and our passions are the only causes of labor; when a nation abounds in manufactures and the mechanic arts, scientific agriculture becomes possible, and the cultivators of the soil redouble their industry and attention, the surplus produce being readily exchanged for the products of those manufactures and mechanic arts, and the land furnishes more than is needed for the support of those who cultivate it; while on the other hand, where this diversified industry does not flourish, there is no inducement for the agriculturists to increase their skill and industry because of the difficulty of exchanging any surplus. Foreign trade by its imports furnishes raw materials for new manufactures, and by its exports gives employment to labor, which in the absence of this trade might be wasted. Necessity is the great incentive to industry and invention—rather the fears than the hopes, the aspirations, and the ambition of mankind. When industry and the arts flourish, the mind acquires new vigor, enlarges its powers and faculties, and at once satisfies its natural appetites and prevents the growth of unnatural ones. The same age which produces great philosophers and politicians, renowned generals and poets, usually abounds in skilled weavers, ship carpenters, and other operatives and mechanics; and "thus industry, knowledge, and humanity are linked together by an indissoluble chain." Progress in the arts is favorable to liberty, and has a natural tendency to preserve a free government by its effects upon the people. Money Hume considers not properly one of the subjects of commerce, but "only the instrument which men have agreed upon to facilitate the exchange of one commodity for another." He holds to the idea that "an increase in the amount of money in a country is rather inconvenient than advantageous, the influence which it exerts being to heighten the price of commodities, and oblige every one to pay a greater number of these little yellow or white pieces for every thing he purchases." Thus did he reason in regard to money, but he could not fail to observe in actual experience an apparent departure from the course here laid down. He had been led to notice that "in every kingdom into which money begins to flow in greater abundance than formerly, every thing takes a new face; labor and industry gain life; the merchant becomes more diligent and skilful, and even the farmer follows his plough with greater alacrity and attention." In order to explain away the discrepancy between these practical results and his theory, he enters into a series of reasonings to show that it is not immediately upon the receipt of this money into a country that a rise in prices takes place, but that "some time is required before the money circulates through the whole state, and makes its effects felt on all ranks of the people." The rate of interest, he holds, "is not derived from the quantity of the precious metals," but "high interest arises from three circumstances: a great demand for borrowing, little riches to supply that demand, and great profits arising from commerce." "I should as soon dread," he adds, "that all the springs and rivers should be exhausted, as that money should abandon a kingdom where there are people and industry. Let us carefully preserve these latter advantages, and we need never be apprehensive of losing the *former*." While deprecating as unwise and illiberal all "those numberless bars, obstructions and imposts," which nations have laid with the object of retaining the precious metals, he says that "all taxes upon foreign commodities are not to be regarded as prejudicial or useless, but those only which are founded upon the jealousy" of the balance of trade. "A tax on German linen encourages home manufactures, and thereby multiplies our people and industry. A tax on brandy increases the sale of rum and supports our southern colonies."—In 1767 there appeared in London "An Inquiry into the Principles of Political Economy, being an Essay on the Science of Domestic Policy in Free Nations," by Sir James Steuart, a countryman of Hume. This was the largest and most elaborate book on the subject which had yet appeared. The various subjects of which it treats in detail are population, agriculture, trade, industry, money, coin, interest, circulation, banks, exchange, public credit, and taxes. Economy in general Steuart defines as the art of providing for all the wants of a family with prudence and frugality. Political economy he regards as an art, and also a science; and among its important objects are "to provide every thing necessary for supplying the wants of society, and to employ the inhabitants in such a manner as naturally to create reciprocal relations and dependencies, so as to make their several interests lead them to supply one another with their reciprocal wants." Population he considers limited by the amount of food produced, and "that when too many of a society propagate a part must starve." He holds that if a nation would aim to be continuously great and powerful by trade, she must first apply closely to the manufacturing of every natural product of the country; and that when a people find the balance of trade to be against them, it is to their interest to take such measures as will correct the evil. He attacks the theory of Locke and Hume respecting the effect of an increased volume in the circulating medium upon prices. He argues that, while the wealth of a country undoubtedly exerts an influence upon the prices of certain commodities, prices are really regulated by "the complicated operation of demand and competition;" and that when Hume says that "the price of every commodity is in proportion to the sum of money circulating in the market for that commodity," it really means that the money to be employed in the purchase of it is a measure of the demand for it; and it in no wise interferes with Steuart's own proposition respecting the operation of supply, which is fundamental.—In 1776 appeared in London the first edition of the great work of Adam Smith, destined to exert so decided an influence on political economy and legislation: "An Inquiry into the Nature and Causes of the Wealth of Nations." This remarkable book treats "of the causes of improvement in the productive powers of labor, and the order according to which its produce is naturally distributed among the different ranks of the people; of the nature, accumulation, and employment of stock; of systems of political economy; of the revenue of the sovereign or commonwealth." Possessed of singular and great merit, it is also distinguished by the absence of clear definitions of terms; by a want of unity, great central principles being merely enunciated but not elaborated, and their importance and their bearing upon other portions of the science not being shown; the illogical and rambling manner in which different subjects are treated; the general absence of method; and the inconsistency and want of harmony among the several parts. "It is only," says Say, "a promiscuous assemblage of the soundest principles of political economy, supported by the clearest illustrations, and ingenious statistical speculations, blended with instructive reflections; it is not a complete treatise on either science, but an ill-digested mass of enlightened views and accurate information." Dr. Smith holds that the annual labor of every nation is the fund which originally supplies it with what it annually consumes, and that the relative proportion which that produce bears to the consumers is the measure of their supply in the necessaries and conveniences of life; that the greatest improvement in the productive power, skill, and judgment of labor has arisen from the division of labor; that the extent of the division of labor is limited by the market for its products; and that labor is the only universal as well as accurate measure of value, or the only standard by which we can compare the values of different commodities at all times and in all places. He says that the demand for labor can only increase in proportion to the increase of the "funds destined for the payment of wages;" and yet, while justly holding that it is labor which supplies a people with what they consume, with a most remarkable inconsistency he says that "the attention of government never was so unnecessarily employed as when directed to watch over the preservation or increase of the quantity of money in any country." In his complicated and contradictory arguments respecting "stock"—which he says consists of two parts, that which the possessor "expects is to afford him revenue," which "is called his capital," and also that which supplies his "immediate consumption"—he involves himself in some of the most serious fallacies to be found in his book, the deductions from which are fatal to much of his system. No portions of his book need to be read with more care in order to escape error than those which treat of stock, or into which his theory of stock enters as an element. Money he terms "the great wheel of circulation, the great instrument of commerce," and adds, that it "makes a part and a very valuable part of the capital" of a country or people, and that when possessed of it we can readily obtain whatever else we have occasion for. "The great affair is to get money; when that is obtained, there is no difficulty in making any other purchase." Here, it will be observed, he recognizes the important fact that money possesses a quality not to be found in any other commodity: its universal acceptability among men, its power to purchase any thing which man desires to sell. In tracing the general progress of wealth, he illustrates the importance which the farmer gains by the diversification of industry as follows: "An inland country naturally fertile and easily cultivated produces a great surplus of provisions beyond what is necessary for maintaining the cultivators; and on account of the expense of land carriage, and inconveniency of river navigation, it may frequently be difficult to send this surplus abroad." When then workmen engaged in other pursuits settle in the neighborhood, "they work up the materials of manufacture which the land produces, and exchange finished work" "or the price of it for more materials and provisions." "They give a new value to the surplus part of the rude produce, by saving the expense of carrying it to the water side, or to some different market; and they furnish the cultivators with something in exchange for it that is either useful or agreeable to them upon easier terms than they could have obtained it before. . . . They are thus both encouraged and enabled to increase this surplus produced by a further improvement and better cultivation of the land; and as the fertility of the land had given birth to the manufacture, so the progress of the manufacture reacts upon the land, and increases the fertility." As the work improves, more distant markets are reached; "for though neither the rude produce, nor even the coarse manufacture could without the greatest difficulty support the expense of a considerable land carriage, the refined and improved manufacture easily may. In a small bulk it frequently contains the price of a great quantity of rude produce. A piece of fine cloth, for example, which weighs only 80 pounds, contains in it the price not only of the 80 pounds weight of wool, but sometimes of several thousand weight of corn, the maintenance of the different working people, and of their employers. The corn, which could with difficulty be carried abroad in its own shape is in this manner virtually exported in that of the complete manufacture, and may easily be sent to the remotest country of the world."—In 1798 appeared anonymously the first edition of "An Essay on the Principle of Population as it affects the Future Improvement of Society," the author of which was the Rev. T. R. Malthus. New revised and enlarged editions have since been published from time to time with the name of the author, the 6th and last in 1826. According to its preface this publication "owes origin to a conversation with a friend on the subject of William Godwin's essay on avarice and profusion in his 'Inquirer.'" In addition to an examination of the principle of population, and as a part of his subject, Malthus reviews the doctrines of Godwin as well as those of Condorcet, both of whom held to the possible progress of man toward future perfection, and a consequent reign of equality, peace, and justice. The doctrines of Godwin in the essay above referred to, and in his "Inquiry concerning Political Justice" (1793), respecting the unequal distribution of the things of this world among the people, were, in the words of a recent American writer, "among the boldest and sharpest protests against the defects and failures of the existing social organization, uttered with a calmness, sobriety, and force of reasoning, that were not to be met by de-

ouncing them as democratic and revolution-
ry, which sufficed for a reply to more intem-
erate writers." Impressed with the justice
f Godwin's protest, as based upon then exist-
g data, Malthus aimed to overthrow it by
resenting evidence that the inequality among
ankind was due to a natural law. Malthus's
eory "remains to this day," says the Ameri-
n writer already quoted, "as the strongest
pology of which despotism is capable." His
rinciple is that "population when uncheck-
d increases in a geometrical ratio, while
ubsistence increases only in an arithmetical
atio;" or, practically stated, that "in two
enturies the population would be to the
eans of subsistence as 256 to 9, in three
enturies as 4,096 to 13, and in 2,000 years
he difference would be almost incalculable."
e does little more than state his proposition,
hen, almost without presenting proof in re-
ard to the actual power of increase in man
nd food respectively, he proceeds to show
hat have been the checks to increase of pop-
lation throughout the various countries of
e world. Population, he holds, "is neces-
rily limited by the means of subsistence,"
nd "invariably increases where those means
crease, unless prevented by some very pow-
ful and obvious check." These checks he
vides into the positive and the preventive.
he former "include every cause, whether
ising from vice or misery, which in any de-
ree contributes to shorten the natural dura-
on of human life," among which may be
umerated "unwholesome occupations, severe
bor, exposure to the seasons, extreme pov-
ty, bad nursing of children, great towns, ex-
sses of all kinds, the whole train of common
seases, and epidemics, wars, plagues, and
mine." The preventive checks include ab-
inence from marriage and sexual intercourse
om considerations of prudence, and all vice
d immorality tending to render women un-
uitful. Few books have formed the subject
f greater discussion and controversy than
is; and it is difficult to say whether those
ho do or who do not now accept its doctrines
rm the larger number. One of the most de-
iled examinations of this book which have
en published is "The Law of Population,"
y Michael Thomas Sadler, M. P. (London,
30). In addition to an elaborate answer to
althus's theory, Mr. Sadler develops a doc-
ine of population. "The prolificness of hu-
an beings," he says, "otherwise similarly
rcumstanced, varies inversely as their num-
rs;" and he presents a mass of evidence to
ove that nature has not "invested man with
fixed and unvarying measure of prolificness,"
t that the Creator has "regulated the pro-
icness of his creatures in reference to the
rcumstances in which his providence shall
ace them, instead of leaving that regulation
the busy, selfish, and ignorant interference
f man." The Rev. Thomas Chalmers, D.D.,
ho had thoroughly imbibed the doctrines of
Malthus, published a volume "On Political Economy in connection with the Moral State and Moral Prospects of Society" (Glasgow, 1832). Fearing "a sweeping, headlong anarchy," he aimed to present the evidence of the "tremendous evil" of over population, and at the same time to appeal to his countrymen to take steps to "avert it from their borders." In 1841 Thomas Doubleday published in London "The true Law of Population shown to be connected with the Food of the People," in which he undertook to demonstrate that "whenever a species or genus is endangered, a corresponding effort is invariably made by nature for its preservation and continuance, by an increase of fecundity or fertility; and that this especially takes place whenever such danger arises from a diminution of proper nourishment," and that consequently "the deplethoric state is favorable to fertility, and that on the other hand the plethoric state is unfavorable to fertility." Thus "there is in all societies a constant increase going on among that portion of it which is the worst supplied with food; in short, among the poorest." "The Westminster Review" for April, 1852, contains "A New Theory of Population," by Herbert Spencer, deduced from the general law of animal fertility. It argues that an antagonism exists between individuation and reproduction; that matter in its lower forms, that of vegetables for instance, possesses a stronger power of increase than in all higher forms; that the capacity of reproduction in animals is in an inverse ratio to their individuation; that the ability to maintain individual life and that of multiplication vary in the same manner also. He further demonstrates that "the ability to maintain life is in all cases measured by the development of the nervous system." A volume entitled "Population and Capital," consisting of lectures delivered before the university of Oxford in 1833–'4, by George K. Rickards (London, 1854), contends by careful induction from facts that the truth is the very reverse of Malthus's theory; "that the productive power of a community tends to increase more rapidly than the number of its inhabitants."—It is probable that no work on political economy has been more extensively read or studied, or has exerted a larger influence in the formation of opinions in the United States at least, than Jean Baptiste Say's "Treatise on Political Economy, or the Production, Distribution, and Consumption of Wealth" (Paris, 1803; 5th ed., 1826). This treatise is in form the most scientific and methodical which had at the time of its publication appeared in any language. "If," says Say, "we take the pains to inquire what that is which mankind in a social state of existence denominates wealth, we shall find the term employed to designate an indefinite quantity of objects bearing inherent value, as of land, of metal, of coin, of grain, of stuffs, of commodities of every description. When they

further extend its signification to landed securities, bills, notes of hand, and the like, it is evidently because they contain obligations to deliver things possessed of inherent value. In point of fact, wealth can only exist where there are things possessed of real and intrinsic value. Wealth is proportionate to the quantum of that value; great when the aggregate of component value is great, small when that aggregate is small. . . . The knowledge of the real nature of wealth, thus defined, of the difficulties that must be surmounted in its attainment, of the course and order of its distribution among the members of society, of the uses to which it may be applied, and further, of the consequences resulting respectively from these several circumstances, constitutes that branch of science now entitled political economy." Subsequently Say published his lectures on the application of the science, under the title of *Cours complet d'économie politique pratique, suivi de mélanges* (Paris, 1828–'9). An examination of this book will show that he had materially altered his views in regard to the subject, and was now disposed to treat political economy as something higher and better than a mere science of wealth. "The object of political economy," he says in this later book, "seems heretofore to have been restricted to the knowledge of the laws which govern the production, distribution, and consumption of riches. And it is so that I have considered it in my treatise upon political economy, published first in 1803; yet in that same work it can be seen that the science pertains to every thing in society." In the same year in which Say's first treatise appeared, Sismondi published in Geneva his *Traité de la richesse commerciale*. At this time Sismondi was a decided follower of Adam Smith; "but," says a distinguished writer, "being an ardent friend of humanity, his views underwent a complete change in the progress of his investigations. No more pleasing task could be offered us than turning through the voluminous works of Sismondi for the evidences of his pure love of human welfare, and his detestation of the science of wealth apart from human well being."—At the request of Alexander I. of Russia Henri Storch prepared for publication his *Cours d'économie politique, ou exposition des principes qui déterminent la prospérité des nations* (St. Petersburg, 1815). "The emperor Alexander, having taken his lessons in political economy from M. Storch," says a recent writer, "determined to carry out in the administration of the empire the lessons he had learned in the closet; but the result proved most disastrous. British goods flowed in in a constant stream, and Russian gold flowed out; and the government was paralyzed, while the manufacturers were ruined. . . . Count Nesselrode issued a circular preliminary to a change of system, in which it was declared that Russia found herself forced to resort to a system of independent commerce; that the products of the empire no longer found markets abroad; that the manufactures of the country were exceedingly depressed; that the coin of the country was rapidly flowing out to distant nations; that the most solid mercantile establishments had become endangered; and that agriculture and commerce as well as manufacturing industry were not only paralyzed but had been brought to the brink of ruin." It was in 1824 that Russia again imposed heavier duties in opposition to the theories of M. Storch.—"The Principles of Political Economy and Taxation," by David Ricardo, which appeared in London in 1817, is held in high esteem among a large body of economists at the present day. The doctrines for which this work is most noted are the theory of rent and the consequent theory of value. The first of these, with which the name of Mr. Ricardo is now always associated, was announced in 1777 by James Anderson, a Scotchman, in a tract entitled "An Inquiry into the Nature of the Corn Laws;" and it seems to have been so completely overlooked and forgotten, that "when in 1815," says an English economist, "Mr. Malthus and Sir Edward West published their tracts exhibiting the nature and progress of rent, they were universally believed to have for the first time discovered the laws by which it is governed." The theories of rent and value, abridged from Mr. Ricardo's own statement, are as follows: On the first settling of a country in which there is an abundance of rich and fertile land, there will be no rent; for no one would pay for the use of land when there was an abundant quantity not yet appropriated. If all land had the same properties, if it were boundless in quantity and uniform in quality, no charge could be made for its use, unless where it possessed peculiar advantages of situation. It is only then because land is not unlimited in quantity and uniform in quality, and because in the progress of population land of an inferior quality or less advantageously situated is called into cultivation, that rent is ever paid for the use of it. When in the progress of society land of the second degree of fertility is taken into cultivation, rent immediately commences on that of the first quality; and the amount of that rent will depend on the difference in the quality of these two portions of land. When land of the third quality is taken into cultivation, rent immediately commences on the second, and it is regulated as before by the difference in their respective productive powers. At the same time the rent of the first quality will rise, for that must always be above the rent of the second, by the difference between the produce which they yield with a given quantity of capital and labor. "The most fertile and favorably situated land will be first cultivated, and the exchangeable value of its produce will be adjusted in the same manner as the exchangeable value of all other commodities, by the total quantity of labor necessary in various forms, from first to last, to produce it, and

ing it to market. When land of an inferior
ality is taken into cultivation, the exchange-
ble value of raw produce will rise, because
ore labor is required to produce it." "This,"
ys one of Mr. Ricardo's followers, "is the
ndamental theorem of the science of value,
d the clue which unravels the laws that reg-
ate the distribution of wealth." By reason of
ese theories of rent and value, if in accordance
ith the facts, the landlord would be enabled
command a steadily increasing rent as the
eld per acre declined, until he absorbed the
tire product of the land; and food would as
adily increase in cost as population increased.
arvation and wretchedness could not fail to
the lot of the mass of mankind under such
condition of things. These theories seemed
aid in accounting for the Malthusian princi-
e of population, and they at once took their
sitions as logically anterior to that doctrine,
d became the foundation of the system now
own as Ricardo-Malthusianism.—In 1821
mes Mill published "Elements of Political
onomy," which is to some extent a state-
nt and abstract elaboration of some of the
trines of Adam Smith and Ricardo in regard
production and distribution, and those of
ltus respecting population. Col. R. Tor-
ns published in 1821 his "Essay on the Pro-
ction of Wealth;" "long since," says Col-
ll, "placed on the list of unsuccessful efforts
settle this subject."—One of the most wide-
known writers on political economy and
tistics at the present time is J. R. McCul-
ch, who prepared the article for the supple-
nt to the "Encyclopædia Britannica," a sep-
ate edition of which appeared in 1825, and
hich has since passed to a 4th edition, under
e title of "The Principles of Political Econ-
my, with some Inquiries respecting their Ap-
ication, and a Sketch of the Rise and Prog-
s of the Science." "McCulloch," says Col-
ll, "belongs neither to the school of Say,
r to the still more refined and strict school
Tracy, Rossi, and Senior. He persists in
nsidering all the topics of political economy
om a practical point of view. He speaks of
science, it is true, but only in that popular
nse in which men speak of the science of
litics, which is a very different sense from
at in which it is employed by Rossi, Senior,
d J. S. Mill."—In the "Encyclopædia Metro-
litana" in 1836, and subsequently in a sepa-
te form, appeared "Political Economy" by
mas W. Senior, professor in the university
Oxford; the subject being, by the plan of
e "Encyclopædia," classed as among the pure
iences. The author of this treatise however
iled to confine his investigations strictly
thin these bounds. "We propose in the fol-
wing treatise," he says in opening, "to give
outline of the science which treats of the
ture, the production, and the distribution of
alth. To that science we give the name of
litical economy." He insists too on limiting
s inquiries to those subjects as the only true

and legitimate ones, and adds, that political economy does not treat of "happiness, but wealth." He even declines to examine into the effects upon society of the possession of wealth, what distribution is most desirable, or what are the means by which any peculiar distribution can be carried into effect by legislation. All of these questions are "of great interest and difficulty, but no more form part of the science of political economy, in the sense in which we use that term, than navigation forms part of the science of astronomy." The premises of the political economist he regards as consisting "of a few general propositions, the result of observation or consciousness, and scarcely requiring proof or formal statement, which almost every man, as soon as he hears them, admits as familiar to his thoughts, or at least as included in his previous knowledge; and his inferences are nearly as general, and, if he has reasoned correctly, as certain as his premises." The fundamental propositions in political economy Mr. Senior thus states: 1, every man desires to obtain additional wealth with as little sacrifice as possible; 2, the population of the world, or in other words the number of persons inhabiting it, is limited only by moral and physical evil, or by the fear of a deficiency of those articles of wealth which the habits of the individuals of each class of its inhabitants lead them to require; 3, the powers of labor, and of the other instruments which produce wealth, may be indefinitely increased by using their products as the means of further production; 4, agricultural skill remaining the same, additional labor employed on the land within a given district produces in general a less proportionate return; or in other words, though with every increase of the labor bestowed the aggregate return is increased, the increase of the return is not in proportion to the increase of labor. Mr. Senior belongs, as can be seen, to the school of Ricardo and Malthus, and believes with them in the limited powers of the earth.—The formation of the German *Zollverein* or customs union, of entire free trade among the several states composing the union, with such a policy as should protect their domestic production from external disturbance, was due to no man more than to Friedrich List. His "National System of Political Economy," first published in Stuttgart in 1841 (English by G. A. Matile, Philadelphia, 1856), is not built upon hypotheses, but upon observation and history. "Nationality," says the English translator, "is the ruling idea of the book; but with his vigorous mind and clear intelligence, he enlarges it until it comprehends every topic of human welfare."—One of the most distinguished of the English political economists of the present day is John Stuart Mill. He defines political economy to be "the science which treats of the production and distribution of wealth, so far as they depend upon the laws of human nature; or the science relating to the moral or psychological laws of the production and distribution of wealth." Again he says: "Political economy may be defined as follows, and the definition seems to be complete: The science which traces the laws of such of the phenomena of society as arise from the combined operations of mankind for the production of wealth, in so far as those phenomena are not modified by the pursuit of any other object." Accordingly, political economy is "essentially an abstract science," and its method "is the *a priori*." "It reasons," he contends, and "must necessarily reason, from assumptions, not from facts." "The conclusions of political economy, consequently, like those of geometry, are only true, as the common phrase is, in the abstract." "That which is true in the abstract is always true in the concrete with proper allowances." Not only "the method *a priori* is the legitimate mode of philosophical investigation in the moral sciences," but "it is the only mode." The *a posteriori* method, or that of specific experience, "is altogether inefficacious," although it may be "usefully applied in aid of the *a priori*." Therefore, "since it is vain to hope that truth can be arrived at, either in political economy or in any other department of the social science, while we look at the facts in the concrete, clothed in all the complexity with which nature has surrounded them, and endeavor to elicit a general law by a process of induction from a comparison of details, there remains no other method than the *a priori* one, or that of abstract speculation." "In all the intercourse of man with nature," proceeds Mr. Mill, "whether we consider him as acting upon it, or as receiving impressions from it, the effect or phenomenon depends upon causes of two kinds, the properties of the object acting and those of the object acted upon. Every thing which can possibly happen, in which man and external things are jointly concerned, results from the joint operation of the law or laws of matter, and the law or laws of the human mind." "There are no phenomena," he continues, "which depend exclusively upon the laws of mind; even the phenomena of the mind itself being partially dependent upon the physiological laws of the body." Mr. Mill acknowledges that "the laws of the production of objects which constitute wealth are the subject matter both of political economy and of almost all the physical sciences;" but he considers that political economy "presupposes all the physical sciences," and adds, that "it takes for granted that the physical part of the process takes place somehow." In other words, it matters not to political economy why, how, or under what circumstances these laws of matter operate. Mr. Mill's design in writing his "Principles of Political Economy" was to produce "a work similar in its object and general conception to that of Adam Smith; "to exhibit the economical phenomena of society in the relation in which they stand to the best social ideas of the present time." He is a full believer in the views of Locke, Hume, and Smith in regard to money; in those of Ricardo on rent, and Malthus on population. He combats with great energy what he terms protectionism, but acknowledges that there is one, and only one case, "in which, on mere principles of political economy, protecting duties can be defensible;" that is, "when they are imposed temporarily (especially in a young and rising nation), in hopes of naturalizing a foreign industry, in itself perfectly suitable to the circumstances of the country."—As early as 1[illegible] it will be found, some attention had been given in the then British colonies of North America to economic studies. In a "Letter from a Gentleman in Philadelphia to his Friend in London," published in that year, known to have been written by John Dickinson, afterward president of Pennsylvania, and a member of congress during the war of the revolution, the current of trade with the mother country, the extent to which that trade had exhausted the colonies of coin, the importance of an emission of paper money properly secured, the policy of promoting manufactures among themselves, and other questions of this character, are examined. On the organization of the government of the United States under the constitution in 1789, Alexander Hamilton was called to the administration of the treasury department. He took his place in the cabinet, Sept. 11, 1789; and on Jan. 14, 1790, he presented to the house of representatives a report on finance, which was followed on April 23 by one on duties on imports; on Dec. 14, on a national bank; and on Jan. 28, 1791, on the establishment of a mint. It would be difficult to find, among all the state papers or treatises on political economy which appeared before the close of the 18th century, any productions of this character surpassing these in a thorough knowledge of the subjects, clearness and precision of statement, and logical exactness. The report of Alexander J. Dallas, secretary of the treasury, to the house of representatives, Oct. 17, 1814, on the national finances, and that of Feb. 12, 1816, in regard to a general tariff of duties, may be mentioned as among the able economic state papers which have emanated from this government. The "Addresses of the Philadelphia Society for the Promotion of National Industry" (1819), and "The New Olive Branch" (1820), subsequently with other papers collected and published under the title of "Essays on Political Economy" (1822), by Mathew Carey, should here be mentioned. Having no taste for speculation in any form, Mr. Carey dealt almost entirely in facts, figures, and references to history; and thus reached the conviction that "there is a complete identity of interest between agriculture, manufactures, and commerce." The first formal treatise on the subject written in the United States is Daniel Raymond's "Thoughts on Political Economy" (Baltimore, 1820). The author endeavors, and with some success, to escape from the complications and inconsistencies of the economists. His examination of some of the arguments of Adam Smith in regard to stock is original, vigorous, and conclusive. John Rae, a Scotchman, published in Boston in 1834 "Statement of some New Principles on the Subject of Political Economy," which has been quoted and highly commended by John Stuart Mill in his "Principles of Political Economy," who says of it: "In no other book known to me is so much light thrown, both from principles and history, on the causes which determine the accumulation of capital."—In 1835 appeared in Philadelphia an "Essay on the Rate of Wages," the first of the works of Henry C. Carey, who argues, in opposition to Say, Malthus, Ricardo, and other economists, that "where wages are highest, there capital increases most rapidly," because in prosperous countries "there is a tendency to the more rapid increase of capital than of population." He took ground against regarding political economy as the science of wealth, and insisted upon considering its "great object" and "its chief claim to attention the promotion of the happiness of nations." This was followed by his "Principles of Political Economy" (3 vols., 1837-'40), in which he demonstrates that value is determined by the cost of reproduction, and that every improvement in the mode of producing any commodity tends to lessen the value of commodities of the same description previously existing. From this it follows that in all advancing countries accumulated capital has a constant tendency to fall in value when compared with labor; that labor is therefore steadily growing in its power to command capital, and *e converso* the power of capital over labor as steadily diminishing; that labor and capital in their combined action are continually producing a larger return for the same outlay, of which larger return an increasing proportion goes to the laborer, while the share of the capitalist diminishes in its proportion, but increases in amount, being taken from a yield so much increased. "No truth so luminous," says a recent writer, "as that contained in this grand law of distribution had ever lighted up the path of inquiry into social science. It gave the clue by which history is made intelligible and consistent, for it alone explains the possibility of that physical, social, and political progress through which all classes advance in their dominion over the power and the stores of nature, with a constant approximation toward equality in their relations toward each other." In 1848 appeared Mr. Carey's work entitled "The Past, the Present, and the Future." Its object was that of demonstrating the existence of a simple and beautiful law of nature governing man in all his efforts for the maintenance and improvement of his condition, which had thus far wholly escaped observation. That law was the one in virtue of which the work of occupation and cultivation of the earth had always of necessity commenced upon the higher, drier, and poorer lands, passing thence, with the growth of wealth and population, to the lower and richer soils, with constant increase in the return to labor. Here was a complete reversal of those assumptions of Malthus upon which he had based his idea of a growing difficulty of obtaining food, as well as of those of Ricardo, which had served as the foundation of his celebrated and generally admitted, though erroneous theory of rent. Further than this, it furnished demonstration of the accuracy of the theory of value and of the law of distribution previously announced by Mr. Carey and above referred to. Passing over several intervening books, we have to notice his last and most extensive one, "Principles of Social Science" (3 vols. 8vo., Philadelphia, 1858-'9). In this the distinction is most clearly drawn between the science, which treats of the natural laws governing the subject, and the art—political economy—by means of which the obstructions to the operation of those laws may be removed. The effect is seen in the breadth of his definition, as compared with that given by all other economists; the latter limiting their science to the discussion of the production and distribution of mere material wealth, while the former defines his subject as being "the science of the laws which govern man in his efforts to secure for himself the highest individuality and the greatest power of association with his fellow man." Man, it is thus seen, is the subject of social science, and he is distinguished from the lower animals by the fact that association is necessary to his existence; that each and every member of the human family is possessed of a distinct individuality, and his development becomes more and more complete as he is more and more enabled to combine and associate with his fellow men; that he is a responsible being, and capable of progress. The more numerous the differences in the demands of society, the more complete becomes the development of the individualities of its members, the greater is the power of association and combination, the more rapid the progress, and the more perfect the responsibility for the proper use of the faculties which have been developed. Here, as everywhere, it is shown that in variety there is unity, and that the nation which would have peace and harmony at home and abroad must adopt a policy which shall develop the infinitely various faculties of its people—the plough, the loom, and the anvil working together, each for the advantage of the others. The social laws are thus, according to Mr. Carey, identical with those which govern matter in all its various forms; differences everywhere exciting forces, forces exciting heat in matter and impulse in mind, and heat and impulse re-exciting motion. Nature's laws being thus universal, the branches of science constitute but one great and harmonious whole, the social parts demanding the same methods of study and investigation. The methodical study of nature does and of necessity must, take the place of the metaphysical. The third chapter of the book is devoted to an exposition of the great series of changes which the earth must undergo in furnishing the residence and support of vegetable, animal, and human life in the order of their respective appearances upon it, the relation and dependence of their various subsistence upon each other, and the circulation of the common elements of their structure, beginning with the disintegrated rock in its simplest forms, and thence ascending through vegetable and animal organisms to that of man, in which their greatest complexity and highest sphere are reached, and whence they are again set free to pass through that never ending circuit which constitutes the entire organic and inorganic creation, one perfectly balanced system of universal exchange—an incessant flux of the forms of matter in their ascent from the simple to the most complex, adjusted precisely to the growing requirements of the successive orders of being in the great scale of vital development. The inert earth with the air and water supplies the demands of vegetable growth, this in its turn supplying the sustenance of the animal world; plants and animals furnishing sustenance to man, and the higher forms of being never outgrowing or overtopping the lower from which they spring, and to which they must of necessity return. Such are the reciprocities of motion, force, and function, in which Mr. Carey finds an order and a system, which as he believes put to flight the doctrine of discords and disproportions announced by Malthus, and since adopted by so large a proportion of the economists of Europe. A chapter on the new doctrine of the occupation of the earth, already referred to, is followed by one devoted to an examination of the much discussed question of value; and an illustration of the breadth of Mr. Carey's views may be given in his definitions of some of the most important terms in general use among teachers of social science. Utility is the measure of man's power over nature. All the utilities developed centre themselves in man, with constant increase of his power, and as constant decline of values, which are but the measure of nature's resistance to the gratification of man's desires. Wealth consists in man's power to command the always gratuitous services of nature. Production consists in directing the forces of nature to the service of man. Every act of consumption is also an act of production, water being consumed in the production of air, air being consumed in the production of water, both being consumed in the production of plants, which in their turn are consumed in the production of men and animals, all of which are finally resolved into the elements of which they are composed, to go their round again in the reproduction of plants, animals, and men. Capital is the instrument by the aid of which the work is done, whether existing in the form of land and its improvements, ships, ploughs, mental development, books, or corn. Trade is the performance of exchanges for other persons, and is the instrument used by commerce, which consists in the exchange of services, products, or ideas by men with their fellow men. As men are more and more enabled to associate together, commerce increases, but the power of trade declines; the growth of the one being here, as in the case of utility and value, in the inverse ratio of the other. Nevertheless, all other economists use these words as being synonymous the one with the other. Money is regarded as the great instrument of association, power growing everywhere with increase in the ability to command the services of the precious metals. Price is the value of a commodity as measured by those metals. Prices of land, labor, and all raw materials tend to rise with every increase in the power of association, that increase being attended by decline in the prices of finished commodities. They tend therefore to approximate, and it is in the closeness of that approximation that Mr. Carey finds the highest evidence of advancing civilization. The definitions here given differ widely from those found in the works of all other economists; but wide as is the difference, it is not greater than that exhibited in Mr. Carey's order of development as compared with that most in vogue. According to the latter, agriculture precedes manufactures, which are followed by trade; whereas Mr. Carey shows, in a series of chapters in which he examines the course of many of the most important communities of the world, that trade appears first, to be followed by manufactures, and that it is not until the latter have been developed and a market is thus made in the neighborhood of the farm, that any real agriculture makes its appearance. The more complete the agricultural development, the greater is the tendency toward an influx of the precious metals, which like other raw materials tend always toward those places at which finished commodities are cheapest; leaving those at which employments are least diversified, to seek those at which association and combination have most existence. Circulating notes diminish the value of the precious metals, but increase their utility, with constant diminution in the rate of interest, and equally constant increase in the tendency toward equality among men, and strength in the communities of which they are a part. The power of accumulation is in the direct ratio of the rapidity of the societary movement, which increases with every increase in the power to maintain that direct commerce which may be carried on without the intervention of the trader. Power grows with every increase in the numbers that can obtain food from any given space; and here, passing over many important chapters, we reach the law of population propounded by Mr. Carey, characterized by great originality and simplicity. Agriculture, as has been seen, becomes more productive as men are more and more enabled to combine together. The more they can combine, the less is the waste of human power in the search for food, and the less the muscular effort required for procuring any given effect; the locomotive of civilized society doing the work that in savage life is done by the shoulders of the man, and the great steam mill grinding the grain that before had required the severest labor. Vegetable food is generally substituted for animal food; the tendency toward this substitution being always greatest in those communities in which growing wealth most manifests itself in the clearing, drainage, and culture of those rich soils which, according to Mr. Ricardo, are cultivated when men are poor, weak, and scattered, but which, according to Mr. Carey, are last brought under human power, their very wealth forbiddding their occupation by the early cultivator. Simultaneously with the changes thus observed, we find the vegetable taking the place of the animal world, and the inexhaustible mineral world taking the place of both; wool being superseded by cotton, flax and cotton superseding silk, gutta percha taking the place of leather, paper being substituted for parchment, coal expelling wood in its use as fuel, the steel pen being used instead of the animal one, the iron horse taking the place of the one of flesh and blood. As individuality becomes developed in man, he obtains from day to day increased power to command the services of nature, and is enabled to feed and clothe himself better; the treasury of nature being unlimited in extent, the supply furnished being in the direct ratio to his power to make demand, and that demand increasing with every step in the growth of the power of association. The more perfect the development of the latent powers of the earth, and the greater the development of mans' peculiar faculties, the greater is the competition for the purchase of labor, the greater is the freedom of man, the more equitable is the distribution of the products of labor, the greater is man's feeling of responsibility for his action in the present and of hope in the future. The higher that feeling, the greater is the tendency toward matrimony as affording the means of indulging affection for wife and children, and the love of home. Vital laws coöperating with the moral, the rational faculties are developed, and the propensities abated and overcome; thus placing man himself under the great and well established law in virtue of which the tendency to reproduction is always in the inverse ratio of development. "Such," says Mr. Carey, "are the various forces to whose combined operation we look for the proper supply of food and raw materials to the demand for them; those forces operating within and without the human system, and tending always to establish among its functions an orderly balance, while displaying their power in bringing up subsistence to the level with a demand that is itself constantly diminishing in its ratio to the numbers to be supplied." The Malthusian theory he holds to be irreconcilably inconsistent with the real laws of nature as seen in the occupation of the earth, and the relative powers of increase in vegetable life and in the lower forms of animal life and in man. The sphere of action of government in directing the commerce of the state is strictly limited to the removal of the obstacles to perfect combination and association. Real freedom of trade consists in the power to maintain direct commerce with the outside world. To reach it there must be a diversity of employments, enabling the exporting country to send its commodities abroad in a finished shape. Centralization, such as is established by the British system, is opposed to this, and therefore it is that that system is resisted by all the advancing communities of the world, they being enabled to advance in the precise ratio with their power to resist it. Protection being the form assumed by that resistance, its object may be properly defined as being that of establishing perfect freedom of commerce among the nations of the world. Societary organization furnishes additional evidence of the universality of nature's laws, for throughout her realms dissimilarity of parts furnishes conclusive evidence of the perfection of the whole—the highest organization presenting the most numerous differences. The higher the organization the more complete the subordination of parts, and the more harmonious and beautiful their interdependence; and the more complete that interdependence the greater the individuality of the whole, and the more perfect the power of self-direction. Such are the doctrines advocated by Mr. Carey; we devote a comparatively large space to them on account of their originality and present prominence.—The names and doctrines of most of the leading economists of Great Britain have been mentioned in the preceding pages. In France, among the more distinguished recent writers may be named Blanqui, Tracy, Louis Say, Droz, Rossi, Chevalier, Dunoyer, Garnier, Baudrillart, Bastiat, Fontenay, Coquelin, Foucher, Reybaud, Wolowski, with a host of others. Germany, although not so prolific in works of this character, has produced many. "The German eclectic works," says Colwell, "furnish a vast amount of well arranged information, and they may always be consulted with advantage. We would refer," he adds, "especially to the works of Schmalz, Jakob Vollgraff, Krause, K. H. Rau, Lotz, Hermann, and Schön; but there are others of equal merit." In Italy much attention has been given to political economy from an early period, and a collection of Italian economists in 50 vols. 8vo. was commenced at Milan in 1806, and completed in 1816. The *Biblioteca degl' economisti*, another collection of Italian and foreign writers, edited by Francesco Ferrara, professor of political economy in the university of Turin, is now in course of publication. A Spanish treatise well worthy of attention is "The Theory and Practice of Commerce and Maritime Affairs," by Geronymo de Uztariz (Madrid, 1724; English, 2 vols.

8vo., London, 1751). In the various universities and colleges of the leading countries of Europe this subject occupies an important position in the course of studies. In the United States treatises on political economy or branches of the subject have been published by Stephen Colwell, Prof. Tucker, Prof. Lieber, Prof. Vethake, Prof. Bowen, President Wayland, Calvin Colton, E. C. Seaman, George Opdyke, Condy Raguet, Peshine Smith, and many others; and some attention has been given to it as a branch of study in colleges.—Among the best books of reference on this subject may be mentioned "The Literature of Political Economy," by J. R. McCulloch (London, 1845), and *Dictionnaire de l'économie politique* (2 vols. 8vo., Paris, 1852–'3), a most complete, trustworthy, and valuable work. "A Dictionary of Political Economy, Biographical, Bibliographical, Historical, and Practical," by Henry Dunning Macleod, is now (1861) in course of publication in London, and will when completed probably extend to 1,500 pages large 8vo. Mr. Stephen Colwell's introductory essay to the American edition of List's "Political Economy" (8vo., Philadelphia, 1856) furnishes a view of what has been accomplished by its teachers, especially within the last 40 years.

POLIZIANO, Angelo, an Italian scholar and author, born at Monte Pulciano in the Florentine territory in 1454, died in 1494. Through the influence of Lorenzo de' Medici, under whose care he was educated, he became canon of St. Paul's cathedral, and at the age of 29 professor of the Latin and Greek languages at Florence, and also the teacher of Lorenzo's children. He stands at the head of the classical scholars who contributed to the revival of learning, and was equally distinguished for his Italian poetry. He made a Latin translation of the history of Herodian and other Greek works, and wrote *Orfeo*, the earliest represented secular drama in a modern language. His Latin works, along with 12 books of letters, were published in Paris (fol., 1512).

POLK, the name of counties in 8 of the United States. I. A N. W. co. of Ga., bordering on Ala., and drained by the Tallapoosa and other streams; area, about 500 sq. m.; pop. in 1860, 6,295, of whom 2,440 were slaves. It has an undulating surface and a light, sandy soil. Capital, Cedartown. II. A S. E. co. of Texas, intersected by Trinity river; area, about 1,200 sq. m.; pop. in 1860, 8,298, of whom 4,199 were slaves. Its surface is nearly level, and the soil along the Trinity very fertile. The productions in 1860 were 60,065 bushels of Indian corn, 13,881 of sweet potatoes, and 582 bales of cotton. There were 60 pupils attending public schools. Capital, Livingston. III. A W. co. of Ark., bordering on the Indian territory, watered by the Washita and several branches of Red river; area, about 1,000 sq. m.; pop. in 1860, 4,262, of whom 172 were slaves. It has a hilly surface and generally fertile soil. The productions in 1850 were 43,405 bushels of Indian corn, 1,892 of wheat, 4,084 of oats, 5,388 of sweet potatoes, 1,910 lbs. of tobacco, and 22 bales of cotton. There were 89 pupils attending public schools. Capital, Dallas. IV. A S. E. co. of Tenn., bordered E. by N. C. and S. by Ga., and drained by the Hiawassee river and one of its branches, the Tocoa or Ocoee; area, about 300 sq. m.; pop. in 1860, 8,726, of whom 434 were slaves. It has a mountainous surface and a moderately fertile soil. The productions in 1850 were 299,917 bushels of Indian corn, 51,572 of oats, 14,727 of wheat, 21,235 of sweet potatoes, 29,266 lbs. of tobacco, and 46,923 of butter. There were 5 grist mills, a saw mill, a tannery, 19 churches, and 700 pupils attending public schools. Capital, Benton. V. A S. W. co. of Mo., watered by the Pomme de Terre river, and branches of Sac river, beside several small streams; area, 750 sq. m.; pop. in 1860, 9,995, of whom 512 were slaves. The surface is undulating or level, and the soil fertile. The productions in 1850 were 308,000 bushels of Indian corn, 14,360 of wheat, 104,925 of oats, 17,173 lbs. of wool, and 60,212 of butter. There were 11 churches, and 864 pupils attending public schools. Capital, Bolivar. VI. A central co. of Iowa, intersected from N. W. to S. E. by the Des Moines river, and across the N. E. by the Skunk river, and watered also by the Raccoon and other branches of the Des Moines; area, 720 sq. m.; pop. in 1860, 11,625. It has a rolling surface and fertile soil. The productions in 1859 were 446,707 bushels of Indian corn, 13,129 of wheat, 7,548 of oats, 10,443 lbs. of wool, 157,896 of butter, and 7,542 galls. of sorghum molasses. Capital, Des Moines. VII. A N. W. co. of Wis., separated from Minn. on the W. by the St. Croix river, and drained by the Shell, Vermilion, Hay, and other rivers; area, 2,304 sq. m.; pop. in 1860, 1,400. It was formed in 1853. Capital, St. Croix Falls. VIII. A W. co. of Oregon, bordering on the Pacific ocean, bounded E. by the Willamette, and watered by the Nokas, Alseya, and La Creole rivers; area, about 1,000 sq. m.; pop. in 1860, 3,625. The soil is generally fertile. The productions in 1850 were 16,373 bushels of Indian corn, 1,605 of oats, 1,218 lbs. of wool, and 36,090 of butter. There were 154 pupils attending school. Capital, Cincinnati.

POLK, James Knox, an American statesman, and the 11th president of the United States, born in Mecklenburg co., N. C., Nov. 2, 1795, died in Nashville, Tenn., June 15, 1849. His ancestors, whose name was originally Pollock, emigrated from Ireland early in the 18th century, and settled on the eastern shore of Maryland, whence some of them removed to the western frontier of North Carolina shortly before the revolutionary war. The father of James K. Polk was a farmer in moderate circumstances, who in 1806 removed to Tennessee, and was one of the earliest settlers of the valley of Duck river, a branch of the Cumberland. The son received at first a scanty education, and was for a while a clerk in a store; but finally, his father consenting to give him a classical education, he entered the university of North Carolina, where he was graduated in 1818 with the distinction of being the first scholar of his class. On returning home he studied law in the office of Felix Grundy, and was admitted to the bar in 1820. He began practice in Maury co., and at the end of a year was already noted as an advocate. In 1823 he was chosen to the state legislature, and for two successive years was a leading member of that body. In 1825 he was elected a representative in congress by the democratic party, whose principles he always steadily maintained. He opposed federal appropriations for internal improvements, a protective tariff, and a national bank, and soon became one of the most conspicuous adversaries of the administration of President John Quincy Adams, while that of President Jackson received through its whole course his warmest support. On several questions of importance he was its most efficient advocate in the house of representatives. In the session of 1833-'4, as chairman of the committee on ways and means, he vindicated with much force the conduct of the president in ordering the removal of the public deposits from the bank of the United States. On the resignation of Mr. Stevenson as speaker toward the close of that session, Mr. Polk was nominated for the vacant chair by the democratic party, but was defeated by a coalition between the whigs and a portion of the democrats in favor of John Bell. At the beginning of the following session Mr. Polk was elected speaker, and was reelected in 1837 at the beginning of the extra session. For 5 sessions he presided as speaker; and at length in 1839, after having served for 14 years in congress, he declined a reëlection, and was chosen governor of Tennessee by a large majority over Governor Cannon. In the following year he received the nomination of the legislature of Tennessee and several other states as a candidate for vice-president with Mr. Van Buren, but at the election received only one electoral vote, Richard M. Johnson of Kentucky being in that contest the regular democratic candidate. In 1841, his term of two years as governor having expired, he was a candidate for reëlection under unfavorable circumstances, the state having given a whig majority of 12,000 at the presidential election of the previous year, and he was defeated by a majority against him of 3,224 votes. Two years later he was again a candidate, and was defeated by a similar vote. The democratic national convention for the nomination of candidates for president and vice-president, which met at Baltimore May 27, 1844, on the first ballot for president gave Martin Van Buren 146, Lewis Cass 83, R. M. Johnson 24, J. C. Calhoun 6, and 7 votes for other persons. Seven ballots followed, on the last of which Mr. Van Buren received 104 votes, Mr. Cass 114, and Mr. Polk 44. The Virginia and New York delegations then retired for consultation, and on their return it was announced that the Virginia delegation would give their entire vote for Polk, and that New York would withdraw the name of Van Buren and cast 35 votes for Polk. On the next ballot Mr. Polk received the unanimous vote of the convention for president, George M. Dallas of Pennsylvania being on the next day nominated for vice-president. These nominations had the effect of uniting the democratic party, which had been disturbed by dissensions between the friends and opponents of Martin Van Buren; and, on the basis of the annexation of Texas and the maintenance of the claim of the United States to Oregon, after a most animated canvass, in which Henry Clay and Theodore Frelinghuysen were the candidates of the whig party, Mr. Polk was elected in Nov. 1844, by a popular vote of 1,335,834 to 1,297,033 for Clay and 64,653 for James G. Birney, the anti-slavery candidate. The votes of the electoral colleges were: for Polk and Dallas, 170; for Clay and Frelinghuysen, 105. Mr. Polk was inaugurated March 4, 1845, and appointed as his cabinet James Buchanan, secretary of state; Robert J. Walker, secretary of the treasury; William L. Marcy, secretary of war; George Bancroft, secretary of the navy; Cave Johnson, postmaster-general; John Y. Mason, attorney-general. At the beginning of his administration the president found the country involved in disputes with Mexico, growing out of the recent annexation of Texas to the United States. He sent Gen. Taylor with a small force to occupy the country between the Nueces and the Rio Grande, the United States claiming the latter river as their boundary, while the Mexicans maintained that Texas had never extended beyond the Nueces. Gen. Taylor was instructed to commit no act of hostility against Mexico unless she declared war or became the aggressor. Meantime the question of the boundary of Oregon engaged the attention of the president and the people. "The whole of Oregon up to 54° 40'" had been one of the watchwords of the democratic party during the recent canvass; and Mr. Polk in his inaugural address had declared that "our title to the country of the Oregon was clear and unquestionable." After negotiation, however, the president directed the secretary of state to offer as the boundary the parallel of 49°, which after some demur was accepted by Great Britain, the proposition being so far modified as to give to that power the whole of Vancouver island. In April, 1846, hostilities broke out on the Rio Grande between Gen. Taylor's army and that of the Mexican commander, Gen. Arista. When the news reached Washington, the president sent a special message to congress declaring that "war existed by the act of Mexico," and asking for men and money to carry it on. Congress responded, May 11, by an appropriation of $10,000,000 and giving authority to call out 50,000 volunteers. Under the direction of Major-Gen. Scott the war was prosecuted with energy and success, and resulted in the entire conquest of Mexico, Santa Anna, the president and most distinguished general of that country, being defeated in several battles, and the city of Mexico itself occupied by the American forces on Sept. 14, 1847. By a treaty concluded in the following February, Mexico ceded to the United States New Mexico and Upper California, and accepted the Rio Grande from its mouth to El Paso as the S. boundary of Texas, thus adding in all about 800,000 square miles to the area of the republic. Soon after the termination of the war gold was discovered in California, an immense emigration thither took place, and the territory was consequently soon sufficiently peopled to claim admission as a state. Notwithstanding the brilliant success of the war, the elections for members of congress in 1846 and 1847 showed that the president had not maintained the popularity which he had enjoyed at the time of his election. In several of the states the war with Mexico was unpopular, being regarded as waged for the extension of slavery and without just cause. The passage in 1846 of a tariff act by congress, based on a revenue principle instead of a protective one like that of 1842, alienated large numbers in other states, especially in New York and Pennsylvania, and led to the gain by the whig party of several representatives from those states. On the organization of the territories acquired from Mexico a new disturbing element of the gravest character was introduced into congress by the question of the prohibition of slavery, the whig majority of the house of representatives being in favor of the "Wilmot proviso," by which slavery would be prohibited, while the democratic majority of the senate was opposed to any such restriction. The influence of this element was strongly manifested in the national conventions of 1848. Mr. Polk, in accepting the nomination of 1844, had unequivocally pledged himself not to be a candidate for renomination. He kept to his word, and in the democratic convention which met at Baltimore in May, Lewis Cass and William O. Butler were nominated respectively for president and vice-president. By the whig convention, which met at Philadelphia on June 1, Zachary Taylor and Millard Fillmore were nominated for the same offices. The whigs and democrats opposed to the extension of slavery combined in forming the free soil party in a national convention held at Buffalo, Aug. 8, 1848, at which Martin Van Buren and Charles Francis Adams were nominated for president and vice-president. The presidential election in the following November resulted in the triumph of the whig candidates, and the administration of Mr. Polk terminated March 4, 1849. Beside the Mexican war, the settlement of the Oregon boundary question, the acquisition and colonization of California, and the enactment of the tariff of 1846, the chief measures which distinguished his administration were the establishment of the independent treasury system, by which the revenues of the government are collected in specie without the aid of banks; the creation of the department of the interior; and the admission of Wisconsin as a state of the Union. Three months after his retirement from office Mr. Polk was seized with illness, and in a few days died. In person he was of middle stature, with a full, angular brow, and quick, penetrating eyes. He was grave but unostentatious in manner and amiable in disposition, and his private character was singularly free from stain or suspicion.

POLKA (Pol. *Polka*, a Polish woman, or Bohem. *pulka*, half), a dance first known at Gitschin, Bohemia, introduced in 1835 at Prague, and performed by Raab, a Bohemian dancing master, at the Odeon theatre in Paris in 1840. It is danced by two persons, advancing together, or whirling as in the waltz. The measure is in $\frac{2}{4}$ time, and the step is elevated, the foot being set down suddenly and almost stamping. Various modifications of this dance have been invented by Parisian dancing masters.

POLLEN, an organized substance filling the interior of the anther of a plant, and effective in developing the embryo so that it may become a perfect seed. The most common form of the pollen grain is spheroidal or triangular; in the umbelliferous plant it is oval; and in some compound flowers it is polyhedral. Structurally the pollen grain has been ascertained to consist of 2 or 3 layers, the outermost being thick, fleshy, and variously marked by ridges, tubercles, points, spines, bristles, or hairs symmetrically arranged, that of the passion flower having chinks; ordinarily, however, the surface is smooth and uniform. The internal layer is thin, membranous, and extensible. Within these layers is a cavity filled with a viscid fluid, sometimes transparent, sometimes rendered opaque by the minute granules (*fovilla*) which float in it. When the pollen grain, conveyed by the wind, by insects, or by other agencies, is lodged upon the stigma, its internal layer is protruded through the outer one in the form of tubes which elongate themselves rapidly and carry the fovilla downward until it reaches the ovule. This being effected, a change takes place in it by which the embryo is originated. The process is called impregnation, and without it no genuine seed can be produced. The ovule and ovary sometimes continue to grow and ripen into fruit without impregnation; but the seeds destitute of the embryo refuse to germinate and prove abortive.

POLLIO, Caius Asinius, a Roman general, orator, and poet, born in 76 B. C., died A. D. 4. He was descended from an obscure family of the Marrucini, and is first spoken of as having come forward at the age of 22 as the accuser of C. Cato, who was acquitted through the influence of Pompey. When the civil war broke out he joined the party of Cæsar, and was with that commander at the passage of the Rubicon and his subsequent march through Italy. Afterward he was sent to Sicily and Africa under Curio, who commanded the forces which drove Cato out of the former country; and when Curio was defeated and slain by Juba, Pollio collected the scattered troops and joined Cæsar. He was present at the battle of Pharsalia in 48, and probably the following year, on his return to Rome, was elected tribune of the people. In 46 and 45 he accompanied Cæsar in his African and Spanish campaigns, and subsequently was sent into Further Spain to carry on the war against Sextus Pompey. While he was there Cæsar was assassinated, and a peace was soon concluded between Pompey and the Romans. After Octavius had united with Lepidus and Antony in forming the first triumvirate, Pollio joined their party, and was nominated by them for consul in 40. When the division of the provinces was made, Antony assigned to him the charge of Transpadane Gaul with the duty of settling the lands among the veterans; and while engaged in this work he was enabled to save the property of Virgil. When Pollio became consul, the poet addressed to him his 4th eclogue. In 39 he was sent by Antony against the Parthini, an Illyrian people, and, being successful in the campaign, had the honor of a triumph. With this he closed his military life, devoting himself thereafter to literature, and occasionally delivering speeches in the senate and the courts of justice. When the war broke out between Augustus and Antony, Pollio declined the invitation of the former to accompany him in his campaign against his old commander, on the ground of his early friendship; and the validity of the excuse was admitted. Pollio occupied a high position in Roman literature as a historian and poet, although but few fragments of his writings have been preserved, including 3 letters to Cicero. He wrote a history of the civil war in 17 books, beginning with the year 60 B. C., and apparently extending down to the battle of Actium. He also wrote tragedies, commended by Virgil and Horace. As an orator, however, he was especially distinguished. He was a patron of many poets and writers, among whom were Virgil and Horace, and established a public library in Rome, in the *atrium libertatis* on Mt. Aventine, from the money procured in his Illyrian campaign.

POLLIO, Trebellius, one of the six writers of the *Historia Augusta*, flourished during the reign of Constantine. His name is prefixed to the lives of the two Valerians, Gallienus, the thirty tyrants, and Claudius; and, according to Vopiscus, the biographies written by him began with Philip.

PÖLLNITZ, Karl Ludwig, baron, a German writer of memoirs, born in Issum near Cologne, Feb. 25, 1692, died June 23, 1775. After having squandered his property, his restless disposition led him to travel over the greater part of Europe. At nearly every court his attractive qualities caused him to be well received, and he entered successively the military service of Austria, of the Papal States, and of Spain. He retained no place long until Frederic the Great chose him for his reader. In this situation, constantly exposed to the ill humor of the king, he was perpetually falling into disgrace, but succeeded in restoring himself to favor, and at last obtained the position of director of the theatre. He was three times converted to the Roman Catholic church, and finally died in that communion. His "Memoirs and Observations on his Travels through Europe" (translated from the French, 4 vols., London, 1737) has passed through several editions, and contains some of the best pictures of court life and intrigue in the 18th century. He wrote exclusively in French.

POLLOCK, a northern fish of the cod family, and genus *merlangus* (Cuv.). As in the cod, there are 3 dorsals and 2 anals, but these are triangular; there is no barbel under the chin; the head is more pointed, and the body more compressed and deeper; the gape large; the tongue fleshy and dark-colored, and the lower jaw the longer; minute teeth in both jaws, but only one row in the lower. The common pollock (*M. purpureus*, Storer) is from 1 to 3 feet long; the head and body above are greenish brown, the sides lighter, and the abdomen white; some smaller specimens are darker above, and reddish below; the ventrals white, anals marked with the same, and the other fins like the back. It is caught abundantly on the New England coast in spring and autumn; its flesh is rather soft, though delicate and nutritious, and from an unfounded prejudice among fishermen it is generally thrown away; when prepared in the manner of dun fish, with proper care and with good salt, it is an excellent fish, worth from $3 to $4 a quintal. The pollock of Europe (*M. pollachius*, Cuv.) is olive brown above the lateral line, on the sides dull silvery white mottled with yellow, and whitish below; dorsals and tail brown, the other fins edged with reddish orange. It abounds in the northern seas, especially on rocky coasts, and is esteemed as food; it is voracious like the rest of the family, eating the fry of other fish, mollusks, crustaceans, and radiates; it is gregarious when in pursuit of food. The black pollock (*M. carbonarius*, Linn.), or the coal fish, is from 1 to 3 feet long, black above, bluish white below the lateral line, and lighter on the abdomen; the lateral line silvery white. It is seen occasionally in our markets, and is found from the coast of New York to Davis's straits on the American side, and in the northern seas as high as Spitzbergen, in the Baltic, and about the Orkneys in Europe. The young in Europe are much esteemed as food by the poorer classes. It attains a weight of 30 lbs.; it swims rapidly, not very deeply, and is in the best condition from October to December, when it readily takes the hook. The northern pollock (*M. polaris*, Sab.) is a species about a foot long, inhabiting the arctic seas. The green pollock (*M. leptocephalus*, De Kay), from New York, is from 1 to 1½ feet long, deep green above the lateral line, and silvery white beneath with minute black dots.

POLLOK, Robert, a Scottish poet and prose writer, born at Muirhouse, Eaglesham parish, in Renfrewshire, in 1799, died near Southampton, Sept. 15, 1827. He was designed for the ministry, studied at the university of Glasgow, and was made a licentiate of the United Secession church in 1827. The severe mental labor he had undergone had so injured his constitution that he determined to make a journey to Italy for the sake of his health, but died before he had embarked. He wrote "Helen of the Glen," "Ralph Gemmell," and "The Persecuted Family," all of which appeared anonymously. The work on which his reputation rests is his poem entitled "The Course of Time," which was published by Blackwood of Edinburgh in 1827 on the recommendation of Professor Wilson. It soon went through many editions, and is yet popular as a religious work.

POLLUX. See Castor and Pollux.

POLLUX, Julius. I. A Greek grammarian and sophist, born at Naucratis in Egypt, flourished about A. D. 183. He studied at Athens, where subsequently he taught grammar and rhetoric. He was severely attacked by many of his contemporaries, especially Lucian and Philostratus. His only extant work is the *Onomasticon*, a dictionary of Greek words classified according to their subjects, with brief explanations of their meaning, and illustrative quotations from the ancient writers. II. A Byzantine author, who wrote a universal history, beginning with the creation of the world, which it discusses at some length, and extending to the reign of Valens, although one manuscript is said to continue the narration to the death of Romanus (963). It is a compilation, and devoted chiefly to ecclesiastical history. There have been two editions, of which the later is that of Hardt (8vo., Munich, 1792).

POLO, Marco, a noble Venetian traveller, born in 1250, died about 1324. He came of an adventurous family. His father Nicolo and his uncle Maffeo Polo sailed shortly before Marco's birth on a trading voyage to Constantinople, and having there exchanged their merchandise for jewels, crossed the Black sea to the Crimea and travelled overland to Bokhara, where they passed several years. Thence they went to Cathay, where Kublai Khan treated them with great honor, and finally intrusted them with an embassy to the pope. Reaching Italy after 19 years' absence, they found the papal chair vacant, and after waiting two years in vain for a new pontiff to be chosen, they set out for the East again in 1271, accompanied by Marco, who was now 21 years old. They passed through Palestine, and in Armenia were overtaken by a messenger from the new pope, Gregory X., who brought them presents and letters for the khan. Traversing the northern part of Persia, they journeyed by the city of Balkh and visited many parts of Tartary; but as they followed no direct track, turning aside now to avoid an inundation or a desert, now because of war, and again because they could not obtain guides, it is next to impossible to describe their route. In the Mohammedan province of Badakhshan Marco fell sick, and the party were detained a whole year. Resuming their journey toward the N. E., they came to the foot of a great mountain ridge, up whose sides they toiled for 3 days, when they found themselves on a vast table-land hemmed in by still loftier hills. From this plateau they proceeded to Cashgar, Yarkand, and Khoten, and reached the city of Lop or Lok on the borders of a great desert of the same name (the desert of Gobi). Crossing this desert, they arrived at Shatchen in Tangut, whence they travelled to the city of Karakorum. When they came within 40 days' journey of Cambalu (probably Peking), the capital of Cathay, they were met by an escort, and conducted with every mark of honor to the imperial city. The khan appointed Marco to an office about his person, and, when he was sufficiently instructed in the language and manners of the Mongols, despatched him on embassies to neighboring chiefs, in which he conducted himself with such prudence that he rapidly rose to higher distinctions. The northern provinces of China, western Thibet, the city of Lassa, then the seat of an active commerce, and the province of Khorassan, were successively visited by the young adventurer, who generally found the khan's favor a passport to the most secret and sacred places. His next expedition was to southern China, where he saw the capital Kinsai, reported to be 100 Chinese miles in circuit. This great city, whose size, allowing for the vast parks, gardens, market places, and open spaces enclosed in it, may after all have been not very extravagantly overstated, is probably the modern town of Hang-chow-foo. For 3 years Marco filled the office of governor of a large city in this part of the empire, and his father and uncle had meanwhile made themselves useful to the khan by instructing him how to make catapults and by other services, so that when the three Venetians asked leave to revisit their native country Kublai at first refused to part with them. At length they were dismissed loaded with wealth and promising to return. In their company was a Persian embassy which had just obtained the daughter of Kublai Khan for their king, and, being unable on account of war to travel by land, had accepted Marco's offer to transport them by water. Their fleet consisted of 14 ships of 4 masts, 4 or 5 of them carrying 250 men each. They touched at Ziambar, Borneo, Lokak, Sumatra, the Nicobar and Andaman islands, Ceylon, and the Carnatic, and sailing up the Persian gulf landed the princess, and were magnificently entertained by the Persian government for 9 months. They then prosecuted their journey by land through Koordistan and Mingrelia to

Trebizond on the Black sea, and taking ship again arrived at Venice in 1295. Bronzed by the suns of 24 years, dressed like Tartars, and speaking their native language with difficulty, it was long before they could persuade their friends of their identity. To convince them, they invited all their old associates to a magnificent entertainment, at which they received them in gorgeous oriental dresses of crimson satin. Putting these off after the guests were seated, they appeared handsomely clad in crimson damask, which was also exchanged after the first course for rich suits of crimson velvet. At the end of dinner, when the velvet was taken off, they were seen in the ordinary garb of the time, and the discarded dresses were divided among the guests. When the cloth was removed Marco exhibited the coarse Tartar garments which they had worn on their travels, and ripping them open took out such a profusion of jewels that the company no longer refused to acknowledge them, though the evidence might just as well have been taken to prove any thing else. They were now overwhelmed with distinctions, and received every mark of respect except having all their stories believed. Even on his death-bed Marco was urged to retract his alleged falsehoods; but he solemnly reaffirmed all his statements, and there is now no doubt that he spoke the truth. Maffeo became one of the principal magistrates of Venice. Marco was intrusted with the command of a galley in the fleet sent against the Genoese, who had appeared off the coast of Dalmatia, and was wounded in the ensuing engagement and carried prisoner to Genoa. During his captivity he dictated to a fellow prisoner the account of his travels, which was finished in 1298. It was probably written and first published in French, and translated into Latin during Marco's lifetime; but it is impossible to determine which of the several discrepant texts in French, Italian, and Latin deserve the name of original. The French and Latin were published by the Paris society of geography in 1824. The work has appeared repeatedly in all the principal European languages. One of the best English versions is that of Marsden, which has been published with notes and commentaries in Bohn's "Antiquarian Library." After 4 or 5 years' detention Marco was set at liberty and returned to Venice, where he married and had two daughters. Marco Polo was not only a veracious but an exceedingly observant traveller, and his narrative is one of the most entertaining of its class ever published. He was the first to make known to Europeans the existence of Japan.

POLTAVA. See PULTOWA.

POLYANTHUS (Gr. *πολύς*, many, and *ἄνθος*, a flower), the name of a variety of the oxlip (*primula elatior*, Jacquin), having brown flowers, which grow in an umbel upon a common scape. The sub-varieties of the polyanthus are almost innumerable, having been selected from peculiarities which agree with an artificial standard of excellence established by florists. In its natural condition the oxlip is to be found occasionally in England, but is more common in the thickets in mountainous pastures of Europe. It has a fleshy and divaricating rootstock with fleshy fibres, from the crown of which issue many toothed and hirsute green leaves, oblong lanceolate in shape, and from their bosom one or more flower stalks about 6 inches high, bearing at the top several pale yellow flowers. The calyx is tubular and 5-pointed, the corolla hypocrateriform and swollen at base; the stamens 5 with short filaments; a single style with a globose stigma; the fruit a capsule full of small brown seeds and enclosed in the persistent calyx. It belongs to the natural order of *primulaceæ*, which embraces a great many beautiful flowering species. Though often treated as a pot plant, the polyanthus succeeds best in the open ground, preferring a soil inclining to clay, but rich and moist. If seed is needed, the strongest and best flowers should be selected and the rest cut away; when ripe it may be kept in the capsule till the time of sowing. Shallow boxes are filled with sifted compost, upon which the seeds are thinly strewn, and a thin coat of compost is carefully laid upon them. A uniform degree of coolness and moisture is best until the young plants have acquired 2 or 3 rough leaves, when they are to be pricked out into large pots and kept in frames as a protection from too much sunshine and heavy rains. When the beds in the open ground have been properly prepared some weeks after, the plants may be carefully transplanted a second time; and on their becoming accustomed to the bedding out, they are to be watched that slugs, worms, and vermin do not destroy the foliage, removing all weeds meanwhile. Protection from cold in winter and early spring will be found necessary to insure success. The cultivation of the polyanthus as a fancy flower originated among the Dutch.—The name of polyanthus is likewise applied to the many-flowered species of daffodil.

POLYBIUS, a Greek historian, born probably about 204 B. C., died about 122. His father was Lycortas of Megalopolis, one of the chief men of the Achæan league, who after the death of Philopœmen became its head. Under the influence and training of his parent he grew up in the knowledge of the science of war and of politics. In the war which sprang up between the Romans and Perseus of Macedon he favored a neutral policy; but when it was deemed advisable by the league to offer assistance to the Romans, he was appointed strategus of the cavalry, and sent to Macedonia to communicate the determination to the Roman consul. The offer was declined, but after Perseus and the Macedonians had been conquered, Caius Claudius and Cneius Dolabella came to the Peloponnesus as commissioners on the part of Rome, and by their orders 1,000 Achæans were carried to Rome to be tried for the crime of not having aided the Romans against the Macedonians. Among these was Polybius. On their arrival in 167 they were distributed throughout the principal towns of Etruria; but through the influence of Fabius and Scipio, the sons of Æmilius Paulus, permission was given Polybius to dwell in their father's house at Rome. Here a strong friendship sprang up between the historian and Scipio, then only 18 years old. After the Achæan exiles had remained in Italy 17 years, the Roman senate granted them leave to return, and Polybius accompanied the 300 survivors of the original 1,000 exiles to their native country. There all his efforts were employed in opposition to the party who were endeavoring to plunge his country into a war with the Romans; but his advice was disregarded, though on a statue subsequently erected to his memory was the inscription that "Hellas would have been saved if the advice of Polybius had been followed." Having joined Scipio, and been present at the destruction of Carthage, he hastened to Peloponnesus after the reduction of Achaia by the Romans, and did so much to mitigate the severity of the victors, that statues in his honor were erected at Megalopolis, Mantinea, Tegea, and other cities. But little is known of the rest of his life, and it has not been ascertained at what precise period he made his various journeys. He accompanied Scipio on his expeditions, and Pliny informs us that the latter furnished his friend with a fleet during the third Punic war, for the purpose of exploring the African coast. It has been surmised that he was present at the capture of Numantia in 133, as according to Cicero he wrote a history of the Numantine war. He also wrote a life of Philopœmen, a treatise on tactics, and another on the equatorial regions. His great work, however, is his history, which consisted of 40 books, and embraced an account of the growth of the Roman power from 220 B. C., where the histories of Timæus and Aratus of Sicyon left off, to 146, the year of the destruction of Corinth. It was divided into 2 parts, which probably were afterward united. The first 2 books are taken up with a history of Rome from the capture of the city by the Gauls to the beginning of the second Punic war, and the first part ends with the conquest of Perseus and the downfall of Macedon. The second part, which may be styled a supplement to the first, reviews the Roman policy, and carries on the narration of events to the downfall of Grecian liberty. Of this work only 5 books remain entire, but fragments of the rest are still extant, many of which are long. The style of Polybius is by no means pure, and in his treatment of his subject he is too didactic; but his judgment was good, and he made great efforts to render his narration accurate. The 5 entire books were first printed at Rome in 1473, in a Latin translation. In 1609 Casaubon printed at Paris an edition, in which all the fragments up to that time discovered were incorporated. The edition of Schweighäuser (8 vols. 8vo., Berlin, 1789–'95) contains a Latin translation and a valuable *Lexicon Polybianum*. The text of this edition was reprinted at Oxford in 1823 in 5 vols. 8vo., with the lexicon. The last edition is that of Immanuel Bekker (2 vols. 8vo., Berlin, 1844), who has added the fragments discovered by Cardinal Mai in the Vatican library at Rome. The best English translation of Polybius is by Hampton (2 vols. 4to., 1772).

POLYCARP, one of the early Christian fathers, born probably in Smyrna about the close of the reign of Nero, put to death in 1[illegible]. He was educated at the expense of Calista, a noble Christian lady of Smyrna, and became a disciple of St. John the evangelist, who on the death of Bucolus consecrated him to the bishopric of his native city. It was probably of Polycarp, the "angel of the church in Smyrna," that the apostle wrote that passage in the Apocalypse: "I know thy works, and tribulation, and poverty (but thou art rich). . . . . Fear none of those things which thou shalt suffer. . . . . Be thou faithful unto death, and I will give thee a crown of life." When the controversy about the celebration of Easter began to run high, he went to Rome to consult Anicetus, who then occupied that see; and though he did not succeed in reconciling the differences between the eastern and western churches, his conferences with Anicetus were conducted in the most amicable manner. He distinguished himself at Rome by his opposition to the Marcian and Valentinian heresies, stopping his ears, as Irenæus relates, whenever false doctrines were uttered in his presence, and exclaiming: "Good God, to what times hast thou reserved me that I should hear such things!" During the persecution under Marcus Aurelius he was seized and carried before the Roman proconsul at Smyrna. Being urged to curse Christ, he replied: "Six and eighty years have I served him, and he has done me nothing but good, and how could I curse him, my Lord and Saviour! If you would know what I am, I tell you frankly, I am a Christian." At these words the populace cried out that he should die at the stake, and hastened to bring fuel for the fire. He refused to be fastened, and met his fate with fortitude and calmness. A contemporary narrator relates that when the fire was kindled the flames disposed themselves around him in the semblance of an arch, leaving his body untouched; upon which a spearman pierced him through, and blood flowed from the wound so profusely as to put out the fire; "and then a dove was seen to fly from the wound, which some suppose to have been his soul clothed in a visible form at the time of its departure." Polycarp wrote several homilies and epistles, all of which are now lost except a short epistle to the Philippians, chiefly valuable as a means of proving, by its use of scriptural phraseology, the authenticity of most of the books of the New Testament. In the time of St. Jerome it was read in the public assemblies of the Asiatic churches.

POLYCLETUS, a Greek sculptor and architect, born probably at Sicyon about 480 B. C. He was a citizen of Argos, and is said to have been the pupil of the Argive Ageladas, in whose school Phidias and Myron were his fellow students. He stood at the head of the schools of Argos and Sicyon, and was judged to have surpassed Phidias in some respects, Phidias being superior in images of the gods, and Polycletus unsurpassed in those of men. His statue of Juno in the temple between Argos and Mycenæ was thought however by Strabo to be equal to the Jupiter and Minerva of his great rival. The goddess was seated on a throne, her head crowned with a garland on which were wrought the Graces and the Hours. The head, breast, arms, and feet were of ivory, and the robe which covered the figure from the waist downward was of gold. A statue which he executed, representing a guard of the king of Persia, was so exquisitely proportioned that it was called the canon or rule, and artists came from all parts to study it. Polycletus also wrote a treatise on the proportions of the human form. He was acknowledged to be the greatest architect of his time, and designed the theatre at Epidaurus, which Pausanias pronounced the finest of Greek and Roman theatres.

POLYCRATES, a Greek tyrant of Samos, celebrated for success in all his enterprises, killed in 522 B. C. In conjunction with his brothers Pantagnotus and Syloson, and with only 15 armed men, he seized the sovereignty of Samos. Having assassinated one brother and banished the other, he strengthened the city, enlisted 1,000 archers and manned 100 galleys, and made war with unvarying success upon the neighboring territories. According to Herodotus, Amasis king of Egypt, his friend and ally, wrote to him to sacrifice his most valued possession in order to forestall the misfortunes that Nemesis must have in store for him. Polycrates accordingly threw into the sea a ring of marvellous value; but after some days the ring was found in the stomach of a fish which had been presented to the tyrant. Amasis, more fearful than ever, then broke off his alliance. Grote, however, thinks it more likely that it was Polycrates who broke the alliance in order to cultivate the friendship of Cambyses, to whom he furnished 40 galleys for the invasion of Egypt. He afterward sustained himself at the same time against an insurrection in his own city and the attack of the Spartans and Corinthians from without; but Oroetes the satrap of Sardis, having lured him into Magnesia under the pretext that he wished with his assistance to revolt, he was seized upon his arrival and crucified.

POLYDORE VERGIL. See VERGIL.

POLYGAMY (Gr. πολύς, many, and γαμεῖν, to marry), a state in which a man has at the same time more than one wife, or a woman more than one husband. The latter custom, sometimes called polyandry, prevails in Thibet and a few places elsewhere. The former has existed from time immemorial, especially among the nations of the East. It prevailed before the flood (Gen. iv. 19), was common among the patriarchs, and was tolerated by the laws of Moses (Exod. xxi. 9, 10, and Deut. xxi. 15). The custom, however, appears to have died out, for in the New Testament we meet with no trace of it, and the passages which refer to marriage seem to imply that monogamy was alone lawful. There are no positive injunctions in the Bible against the practice. In the East the custom has been almost universal, being sanctioned by all religions, including that of Mohammed, which allows a man to have 4 wives; but the permission is rarely used except by the rich, and the Arabs scarcely ever have more than one wife. Voltaire, Montesquieu, and others have accounted for the custom on the ground of the premature old age of the female sex in those regions, and Montesquieu also on the ground that the number of females there is much larger than that of males; but this assertion, though supported by the authority of several travellers, seems to be devoid of truth. Among the Greeks, at least of later times, polygamy was never practised, although in the Homeric age it seems to have prevailed to some extent. In republican Rome it was not known; but during the existence of the empire the prevalence of divorce gave rise to a state of things almost analogous with it. In the Christian church it has never been tolerated. It prevailed among the barbarous nations of antiquity, with the exception of the Germans, who, Tacitus says, "almost alone among the barbarians, are content with a single wife."—In England the punishment of polygamy was originally in the hands of the church. A statute of Edward I. placed it among the capital crimes; but it did not come entirely under the control of the temporal power until a statute of James I. made it punishable with death like other cases of felony. By a statute of George III. it was made punishable with imprisonment or transportation for 7 years. By the laws of ancient and modern Sweden the penalty is death. The Prussian code of 1794 subjected the criminal to confinement in a house of correction for not less than one nor more than two years. In the United States, the punishment varies in the different states, being usually imprisonment for a certain period, or fine, the second marriage being of course a nullity. In these countries, however, the term bigamy is most in use, as the plurality seldom extends beyond two; and in legal proceedings it is even employed where that number is exceeded.—In modern times polygamy has had some defenders, most of whom have grounded their defence on the absence of an express prohibition in the Scriptures. Bernardus Ochinus, general of the Capuchin order and afterward a Protestant, published in the 16th century "Dialogues in favor of Polygamy," to which Beza replied.

A still stronger view was taken in a work called *Polygamia Triumphatrix*, published at London by John Lyser, a Lutheran divine (1692). It was boldly maintained in a treatise called *Thelyphthora*, by the Rev. M. Madan, who however limited the privilege to men. He claimed that St. Paul's injunction that a bishop "should be the husband of one wife," implies that other men should have as many as they choose. Singularly enough, the Mormons, the only sect among Christian nations in which this custom is still practised, explain this same passage as meaning that a bishop should be the husband of one wife at least, and that there is no prohibition of his having more if he wishes. Polygamy was introduced among the Mormons by a revelation of Joseph Smith in 1843, but for some years existed as a secret institution. One principal ground upon which it is defended is, that unmarried women can in the future life reach only the position of angels, who occupy a very subordinate rank in the Mormon theocratic system, being simply ministering servants to those more worthy.

POLYGLOT (Gr. πολυς, many, and γλωττα, a tongue), a book with versions of its text in several languages. In common use the word is generally restricted to the Bible. The *Biblia Hexapla* of Origen is regarded as the first polyglot, though only two languages are used in it. Only some fragments of this work have come down to us, and these were published at Paris in 1714. In 1501 Aldus Manutius planned a polyglot in Hebrew, Greek, and Latin, but only one sheet of it was printed. The Complutensian polyglot is the earliest of the several Bibles properly called polyglots. It was printed at Complutum, the Latin designation of Alcala in Spain, at the expense and under the superintendence of Cardinal Ximenes, by whom it was dedicated to Pope Leo X. Seven learned men were employed upon the work. Though begun in 1502 and finished in 1517, it was not published until 1522, in 6 vols. fol. In the Old Testament each page contains 3 columns. Upon the left-hand page are the Hebrew, the Vulgate, and the Septuagint; and upon the right-hand page, the Septuagint, the Vulgate, and the Hebrew. There are Hebrew primitives in the outer margin, and a Latin interpretation of the Septuagint at the top of the page; at the bottom of the page is a Chaldaic paraphrase, with a Latin interpretation in 2 columns. In the New Testament each page has the Greek text and the Latin Vulgate in separate columns, with marginal references. Of this work only 600 copies were printed, and it is now very scarce. The Antwerp polyglot was printed by Christopher Plantin, at Antwerp (8 vols. fol., 1569–'72). The work was conducted by Arias Montanus, who had about 60 assistants, and was published under the sanction of Philip II. of Spain. It is doubtful whether the king undertook the expense, or only lent Plantin the money. This Bible contains the whole Complutensian polyglot, with a second Chaldaic paraphrase of a part of the Old Testament, a Syriac version of the New Testament, and the Latin translation of Sanctes Pagninus, altered by the editor Arias Montanus. Vols. vi., vii., and viii. consist of lexicons and grammars. Of this polyglot 500 copies were printed, and the greater number of these were lost at sea on their way to Spain, so that it is even more scarce than its predecessor. A third was printed at Paris by Antoine Vitré (10 vols. large fol., 1628–'45), edited by Guy Michel le Jay, who had several learned associates. This work contains all that is in the Complutensian and Antwerp polyglots, with an Arabic version of the Old and New Testaments, a Syriac version of the former, and the Samaritan Pentateuch. A work superior to all these is the London polyglot, edited by Brian Walton (6 vols. large fol., 1654–'7). In the course of this work 9 languages are used, viz.: Hebrew, Chaldaic, Samaritan, Syriac, Arabic, Persian, Ethiopic, Greek, and Latin. No one book, however, is given in all these, but portions of the work are printed in 7 languages, all open at one view. The polyglot most accessible to scholars is the one known as Bagster's, published by the London bookseller of that name (1 vol. fol., 1831). This gives the Old Testament in 8 languages, and the New Testament in 9. Eight languages are exhibited at one view, viz.: Hebrew, Greek, English, Latin, German, Italian, French, and Spanish. The New Testament in Syriac, the Samaritan Pentateuch in Hebrew characters, the notes and readings of the Masorite, and other variations, are appended. A polyglot known as Hutter's Bible, extending however only to the end of the book of Ruth, was printed at Hamburg in 1599, in 6 languages, and a Testament in 12 languages, viz.: Hebrew, Chaldaic, Greek, Latin, German, Bohemian, Italian, Spanish, English, French, Danish, and Polish. Two editions of the Pentateuch were printed at Constantinople, one in 1547, the other in 1551, with versions of the text in 4 languages, but all in Hebrew characters. A copy of the Lord's prayer was printed at Paris in 1805 by M. Marcel in 90 different languages, and with characters proper to each. This work was prepared as a compliment to Pope Pius VII. during his sojourn in Paris, and was a masterpiece of typography.

POLYGNOTUS, a Greek painter, born in the island of Thasos about 493 B. C., died about 426. On Cimon's return to Athens from the expedition against Thasos in 463, Polygnotus accompanied him, and was employed by him in the decoration of the temple of Theseus, the Anaceum, and the Pœcile. About 460 he was engaged with Phidias on the temple of Athena Area at Platæa, where in conjunction with Onatas he painted the walls of the portico. Soon after the death of Cimon he went with other artists to Delphi to decorate the edifices connected with the great temple. He returned to Athens in 425, and was employed upon the Propylæa. Polygnotus painted both on walls, and, in the more usual manner of Grecian artists, on panels, which were afterward let into the walls. In the Stoa Pœcile at Athens he represented the Greeks, after the fall of Troy, assembled to judge the case of Cassandra's violation by Ajax. In the Anaceum, or temple of the Dioscuri, he painted the "Marriage of the Daughters of Leucippus." Polygnotus was recognized in his time as at the head of his art. He was the first who gave any variety to the expression of the countenance, or any ease or grace to the outlines of figures or the flow of drapery. According to Pliny, he was the first who used the *sil* or yellow ochre found in the Attic silver mines, and he also made a new pigment of black from the husks of pressed grapes.

POLYHYMNIA (Gr. πολύς, many, and ὕμνια, dreams, or μνεία, memory, or ὕμνος, hymn), in Greek mythology, one of the nine Muses. She presided over rhetoric and the higher lyric poetry. The invention of rhythm was ascribed to her, and her attribute is therefore a lyre. Upon ancient monuments she is represented in an attitude of meditation, the chin reposing upon the right hand.

POLYNESIA, a name applied by geographers to all the islands north or south of the equator, lying between the Philippines, New Guinea, New Britain and neighboring islands, Solomon's islands, New Hebrides, and New Zealand, and the W. coast of America. The principal islands included in Polynesia are the Sandwich, Society, Marquesas, Paumotu, Navigators', Friendly, Feejee, Ladrone, Marshall, and Gilbert groups. The term Polynesia (Gr. πολύς, many, and νῆσος, island) was given by French geographers to the various islands scattered over the Pacific, including Australia; but latterly it has been restricted to the limits here defined.

POLYNICES. See Eteocles.

POLYP (Gr. πολύς, many, and πούς, foot), a name formerly applied to the 3 classes of *radiata*, the coral animals and *actiniæ*, jelly fishes or *medusæ*, and the echinoderms (star fishes, sea urchins, and holothurians). The name as thus extended was given from the numerous prehensile organs around the mouth, like those of the cephalopods (cuttle fishes); now it is generally restricted to the first class, called zoophytes by Prof. J. D. Dana in his "Report" (8vo., New Haven, 1859). He defines polyps as radiated animals, usually attached at the base, with a coronet of tentacles above and a toothless mouth in the centre, with an inner alimentary cavity to which the mouth is the only opening; they are hermaphrodite, reproducing by buds and eggs, with very imperfect circulation and no special organs of sense. He divides them into 2 orders, *actinoidea* and *hydroidea*; but as the latter have been shown by Agassiz to be related rather to acalephs than to polyps, the present article will be chiefly devoted to the former. The *actinoidea* are characterized by a visceral cavity enclosing the stomach, and divided into compartments by radiated plates having reproductive functions, the ovules being rejected through the mouth. They include 2 sub-orders, *actinaria* and *alcyonaria*; the former have 6, 12, or more tentacles, with few exceptions not papillose, perforated at the apex; often coralligenous; coralla calcareous, very rarely corneous, the cells radiate with lamellæ. They include the following tribes: I. *Astræacea*, with many tentacles in imperfect or scattered series; when gemmiparous, gemmation is superior, the polyps widening above. Here belong the families *actinidæ* (the non-coralligenous and usually attached *actiniæ* or sea anemones), the calcareo-coralligenous *astræidæ* (like *astræa* and *meandrina* or star and brain coral), and the coralligenous *fungidæ*. II. *Caryophyllacea*, having numerous tentacles in 2 or more series; mostly gemmiparous, the gemmation inferior and the buds lateral; embracing the coralligenous families *cyathophyllidæ*, *caryophyllidæ*, and *gemmiporidæ*, and the non-coralligenous *zoanthidæ*. III. *Madreporacea*, having tentacles, usually 12, in a single series; gemmiparous, gemmation lateral; with the coralligenous families *madreporidæ*, *favositidæ*, and *poritidæ*. IV. *Antipathacea*, having 6 tentacles, forming at the base corneous secretions; with the single family *antipathidæ*, the animals of which are fleshy, enveloping a corneous spinulous axis. In the sub-order *alcyonaria* the animals have 8 papillose tentacles, the papillæ perforate at apex, often coralligenous, with coralla calcareous or corneous and rarely silicious, and the cells never radiate within. It includes the families *pennatulidæ* (sea pens and rushes), either free or with the base buried in the mud; *alcyonidæ* (sea paps and dead man's hands), fleshy, usually with scattered calcareous granules; *cornularidæ*, forming corneous tubular coralla; *tubiporidæ* (organ corals), forming calcareous tubular coralla; and *gorgonidæ* (sea fans and shrubs), forming basal epidermic secretions, and often other tissue secretions separable from the former. (See Actinia, and Coral, for details of structure and mode of growth.) The order *hydroidea* is characterized by a simple internal cavity, and ovules growing outward from the sides; it includes the families *hydridæ*, *sertularidæ*, *campanularidæ*, and *tubularidæ*.

POLYPHEMUS, in classical mythology, the principal of the Sicilian Cyclops, a son of Neptune, who is represented by Homer as a shepherd dwelling alone in a cave. Ulysses and his followers having taken refuge in this place, they were discovered by Polyphemus on his return from feeding his flocks, and by him were fastened in the cave with a huge stone. Having eaten two of them for supper and two more for breakfast, he then went off to pasture his flocks; and when he came back Ulysses succeeded in rendering him intoxicated, in which condition he fell asleep. Hereupon

Ulysses bored out the single eye of the monster, and the next morning fastened himself and his companions to the bellies of the gigantic sheep as the blind Cyclops let them out to pasture, and thus escaped.

POLYPUS, a name applied in pathology to various morbid growths projecting into the mucous cavities and passages, having their origin either in or beneath these membranes. These growths or excrescences may be in the vicinity of the natural openings of the body, as in the nasal fossæ and rectum, and therefore within the sight and reach of the surgeon; or interior, as in the uterus, bladder, &c., inaccessible to his eye and very often to his instruments. They are usually single, sometimes multiple; their extent is very variable, according to their time and freedom of growth, and their surface may be inflamed or ulcerated. There are two principal varieties of form: the pediculated, with a more or less long and narrow neck, as in the nasal passages; or sessile, in which the morbid mass simply raises the tegumentary membrane. Some are easily crushed, others are very hard. In the soft, mucous, or vesicular polypus, the appearance is semi-transparent, gelatinous, consisting of a mass of areolar tissue, containing an albuminous fluid, covered by a thin adherent membrane; it sometimes contains vesicles; the vessels are few and fine. Themselves insensible, these tumors trouble only by their volume, rarely cause hæmorrhage, irritation, inflammation, or any grave symptom, and do not degenerate into malignant disease; they are also hygrometrical, growing larger in damp weather; nothing positive is known as to their causes. A more solid form of polypus consists of a concrete, grayish albumen, enclosed in areolar tissue, covered by a slightly vascular membrane. In the spongy polypus the tissue is soft, red, vascular, often giving rise to troublesome bleeding, and prone to undergo cancerous degeneration. The fibrous polypus may acquire a considerable size, and is generally pear-shaped, though sometimes of very strange forms; it is lobulated, smooth, and firm, except when subsequently softened and ulcerated; itself insensible, it may cause pain by pressure on surrounding parts; when softened or gangrenous, it may lead to bleeding or to offensive discharges equally exhausting. The fleshy polypus is vascular, painful, and prone to degeneration; the cartilaginous forms may undergo more or less osseous transformation. Polypus is generally a product of inflammation, sometimes of hypertrophy of the mucous membrane, and at others a fibrinous concretion which has become organized; to the first class belong the fleshy forms, to the 2d the mucous, and to the 3d the fibrous. According to their situation they impede the functions of organs; impairing smell and taste when in the nasal cavities, in the pharynx interfering with swallowing, in the auditory meatus with hearing, in the larynx with the respiration and the voice, in the rectum with defecation, in the bladder with the excretion of urine, and in the uterus with reproduction. The treatment consists of local applications for drying up or destroying the growth; or of excision, tearing off, laceration, seton, compression, ligature, and similar applications of modern surgery. In the nose the common form of the polypus is the gelatinous, and its favorite attachment the turbinated bones; its presence is indicated by a constant stuffed feeling as from a cold in the head, increased in damp weather; it may generally be brought into view by forcing air through the affected nostril, while the other is closed; there are sometimes more than one, and they are very liable to return when removed; if allowed to remain, the increasing size blocks up the nostril and displaces the septum, producing often great deformity on the cheek and about the eye; it is generally twisted off from its narrow peduncle by forceps. The hydatid, cancerous, and fungoid polypi admit only of palliative treatment. Uterine polypus is generally pear-shaped and attached by a narrow neck; the symptoms are those of uterine irritation, such as dragging pains, menorrhagia, and finally fetid discharges; it is generally removed by ligature. In other polypi near the external openings of the body the principles of treatment are the same; in the internal forms the diagnosis is obscure, and the treatment simply palliative.

POLYXENA, daughter of Priam and Hecuba, and beloved by Achilles. One legend relates that Achilles, for the sake of obtaining her in marriage, promised Priam to make peace between the Greeks and Trojans, and, going to the temple of the Thymbræan Apollo to conclude the negotiations, was treacherously slain by Paris. Polyxena was therefore sacrificed to his manes, according to one account on his tomb, according to another on the coast of Thrace. Another form of the legend represents Polyxena and Achilles to have fallen in love when the dead body of Hector was given up, and that when the Greek champion was slain she killed herself upon his tomb.

POMBAL, DOM SEBASTIÃO JOSÉ DE CARVALHO, marquis of, a Portuguese statesman, born in Soura, near Coimbra, in 1699, died in Pombal, May 8, 1782. He belonged to an old family of the lesser nobility, studied law at Coimbra, and entered the army, which he abandoned after a short period. Banished from Lisbon on account of quarrels, he spent several years in study at Soura. While there he gained the favor of a rich widow, Dona Teresa da Noronha-Almada, with whom, as her relatives bitterly opposed the match, he eloped. His wife's family treated him with contempt; and stung by their conduct he went to court, and through the influence of his uncle, Paulo Carvalho, was sent to England as secretary of legation. In 1745 he was recalled, but being a favorite with the queen was despatched to

Vienna to settle the dispute between the pope and the empress Maria Theresa in regard to the suppression of the archbishopric of Aquileia. There he gained general favor, and, as his first wife was dead, married the countess Daun, niece of the general of the same name. On his return he found his prospects improved by the affection with which the queen, who was an Austrian princess, regarded his wife; but the animosity of the high nobility was still sufficient to hinder his advancement. Concealing his real feelings, he gained the favor of the Jesuits, and on the death of John V. in 1750, and the accession of Joseph I., he obtained through the agency of the queen mother the position of foreign secretary. His energy, decision, and administrative talent soon gained him a complete control over the mind of the weak monarch. The kingdom at that time was in a miserable condition, without an army or navy, commerce or agriculture. He limited the power of the church and the inquisition, resumed the crown lands and checked abuses in the colonies, and expelled the Jesuits from their missions in Paraguay. He was everywhere met with the most bitter resistance, but his genius and perseverance overcame all opposition. The great earthquake of Nov. 1, 1755, which buried many thousand persons and destroyed an immense amount of property, gave him ample opportunity to display his ability in the restoration of order and the relief of distress. He was subsequently created count of Oeyras, and made prime minister. He now prosecuted his plans with the utmost rigor, removing and crushing all who obstructed them. His monopolies excited the wrath of the country people and of foreigners, especially of the English, who had hitherto held almost all the commerce of Portugal in their own hands. The vine dressers who were unwilling to plant corn saw their vineyards torn up by the roots. The ruffians who had been in the habit of plundering and assassinating in the very streets were shot down without hesitation. The Jesuits were removed from the person of the king, and on Sept. 16, 1757, they were ordered to retire to their colleges. Several of the Portuguese nobility were exiled from Lisbon. An attempt to assassinate the king on the night of Sept. 3, 1758, far from deterring Pombal from his purposes, gave him renewed power by placing in his hands the lives of his enemies. Three months afterward a number of the nobility were suddenly arrested. The duke of Aveiro and the marquis of Tavora, who were the principals in the conspiracy, were broken on the wheel, and others of their accomplices were put to death. The Jesuits were accused of being in the plot; some of them were executed in prison, and by a royal decree of Sept. 3, 1759, the whole body was banished from the kingdom. They refused to quit the country, whereupon they were seized to the number of 1,854, and transported to the Papal States. A quarrel now began with the pope in consequence of these proceedings, and Pombal expelled the papal nuncio, and made preparation to break with the church. The accession to the pontifical throne of Clement XIV., who in 1773 abolished the order, prevented any collision with Rome. Two short wars with Spain followed, in which the Portuguese army was organized on a new basis, and the frontiers were put in a better state of defence. A general system of education was devised, the study of physical and mathematical sciences was introduced, new kinds of crops were cultivated, navigation and ship building were taught, and the censorship was made less strict. The power of the minister was almost despotic, and while he used it for the elevation of his countrymen, he also used it mercilessly to take vengeance on his enemies, by whom his life was several times attempted. On the death of Joseph I. in 1777 he was dismissed by Pedro III., the state prisoners imprisoned by his order were set free, and his projects and regulations were given up. Portugal soon sank into a condition as weak and distracted as before, though Pombal handed over a well organized government with ample revenues. His enemies clamored for his life, but, attacked on all sides, he did not lose his defiant spirit. Though hated and assailed, the queen protected him, and he retired in safety to the village of Pombal, where he spent the remainder of his days in retirement.

POMEGRANATE (*punica granatum*, Linn.), a fruit native in the East and celebrated from a very remote period. The pomegranate tree has an arborescent stem with angular branchlets becoming spiny; deciduous, opposite, rarely whorled or alternate, oblong lanceolate, entire leaves; scarlet flowers 2 to 5 together, terminal upon the smaller twigs and nearly sessile; calyx with a top-shaped tube, its limb with 5 to 7 lobes and the æstivation valvate; petals 5 to 7; stamens numerous with distinct filaments bearing anthers on the inner side; style 1; stigma 1; fruit spherical, indehiscent, crowned by the upper portion of the calyx, divided into 2 portions by a horizontal diaphragm, the upper consisting of 5 to 9 cells, and the lower of 3 cells; seeds very numerous, surrounded by a transparent pulp; embryo oblong; radicle short, straight, its cotyledons leafy and spirally convolute. It belongs, as Lindley has shown, to the natural order *myrtaceæ* (see MYRTLE), though separated by Don into a distinct order termed *granateæ*, principally on account of a peculiarity in the fruit, which cannot be considered as strictly typical.—The pomegranate tree is usually a thorny bush, though it has been known to grow in a wild condition to the height of 18 to 20 feet. The dwarf pomegranate (*P. nana*, Linn.), with a shrubby stem 3 to 4 feet high, linear leaves, and red flowers, is a native of the Caribbee islands and of South America about Demerara, yet probably, as Persoon suggests, is only a variety of the common pomegranate. There are however 5 distinct varieties of the pome granate, viz.: the red-flowered, with the pulp of the fruit of a reddish color; the double red-flowered, commonly cultivated in gardens for its beauty, and there in pots and tubs on account of its tenderness; the whitish-flowered, with white petals and yellowish calyx, the pulp of the fruit of a pale red color; the double whitish-flowered, which is the tenderest of all; and the yellow-flowered, which is rarely seen. The second kind named is a charming shrub, and worthy attention among floriculturists. London speaks of one, trained against the walls of Fulham palace, which grew 40 feet high and 50 feet wide. The single pomegranate will grow in almost any soil, but the double-flowered variety requires a very rich one. It can be propagated readily from the fresh seeds, from pieces of the root, layers or cuttings, or by grafting upon the single kind. The bush needs much pruning and clipping. In the south of Europe the pomegranate tree is cultivated for its fruit and for an ornamental tree, and used as a hedge plant. The pulp of the fruit is acid, sometimes sweet, sometimes vinous, astringent, and refreshing. In most parts of Persia the fruit is delicious, and in the gardens under the snowy hills near the Cabool river there are famous varieties without seeds. A sirup prepared from the pulp is employed as a detergent and astringent. The rind of the fruit has been used instead of galls in making ink, and in Germany for dyeing leather in imitation of morocco. In India the bark of the root is employed in expulsion of the tapeworm, and the same use of it is known among the negroes of the West Indies.—The pomegranate was well known to the ancients, as is clear from numerous allusions in their writings. It was in high repute among the Hebrews, and employed by them in architectural ornament. The city of Granada is supposed to have derived its name from the numerous pomegranate trees planted near it, which is corroborated by its bearing a split pomegranate in its coat of arms.

POMERANIA (Ger. *Pommern*, from *po more*, Slavic words signifying "beside the sea"), a duchy now belonging to Prussia, bounded N. by the Baltic sea, E. by West Prussia, S. by Brandenburg, and W. by Mecklenburg; area, 12,153 sq. m.; pop. in 1858, 1,328,381, nearly all Lutherans except about 12,000 Roman Catholics and 12,000 Jews. It is divided by the river Oder into Hither Pomerania (*Vorpommern*) and Further Pomerania (*Hinterpommern*). Along with a part of the old Neumark and a few places in West Prussia, Pomerania now constitutes the province of the same name, which is divided into the three districts of Stralsund on the W., Stettin in the centre, and Köslin on the E., and also into 26 circles. There are 72 towns, of which the most important are Stralsund, Stettin, Kolberg, Köslin, Greifswalde, Stargard, and Kammin. The largest river is the Oder, which forms below Stettin the lake of Damm, then flows into the Frisches-Haff, and from thence into the Baltic by 3 channels, called the Peene, the Swine, and the Dievenow. Other principal rivers are the Persante, Rega, and Ihna. There are numerous lakes, of which the principal are those of Kummerow, Plöne, and Madüe. On the N. coast lie the 3 islands of Rügen, Usedom, and Wollin. The face of the country is generally level, the province being one of the flattest in Germany. The coast, which is low, is protected by sandhills and dikes, which are often changed about by the winds. The soil is mostly sandy, and generally of moderate fertility, portions being stony and sterile, while some parts are very fertile. The province is poor in minerals; bog ore, alum, salt, amber, chalk, marl, and peat are produced. The inhabitants are German, and in the N. E. portion are Kassubs, descendants of the Slavic Wends, who still preserve their own language. Linen is manufactured, and also cloth, serge, and other woollen fabrics. The trade of the province is important, of which Stettin with its port of Swinemünde is the chief seat.—Pomerania was formerly a principal portion of the old Wendish monarchy, but from 1062 had a line of dukes of its own, which terminated with the death of Bogislas XIV. in 1637. It was frequently overrun by the early Polish monarchs. Christianity was introduced in the 12th century, the first Pomeranian convert having been baptized on June 15, 1124, by Bishop Otho of Bamberg. After the dying out of the line of Pomeranian dukes, the electoral house of Brandenburg had a claim to the whole country by right of former treaties; but as during the 30 years' war the province had come into the possession of Sweden, the house of Brandenburg was forced to content itself with Further Pomerania. At the peace of Stockholm in 1720 Sweden gave up to Prussia the greater portion of Hither Pomerania, along with the islands of Wollin and Usedom, but continued to hold the district between Mecklenburg, the Baltic, and the river Peene, with the island of Rügen. This the former power ceded to Denmark as a compensation for Norway; and by the convention of June 4, 1815, it was given up to Prussia in exchange for the duchy of Lauenburg and the sum of 2,600,000 thalers.

POMERANUS. See Bugenhagen.

POMFRET, John, an English poet, born in Luton, Bedfordshire, in 1667, died in 1703. He was graduated at Queen's college, Cambridge, in 1684, took orders, and in 1699 published a collection of occasional poems and some Pindaric odes imitated from Cowley. His principal poem, "The Choice," describing a life of retirement and moderate wealth, was once reckoned the most popular poem in the English language.

POMMER. See Bugenhagen.

POMPADOUR, Jeanne Antoinette Poisson, marchioness de, mistress of Louis XV., born in 1721, died in 1764. She was the natural daughter of a butcher who had been obliged to flee on account of some dishonest transactions. *Her* mother gave her a good education, and married her in 1741 to a farmer of the taxes named Le Normand d'Étioles, shortly after which she first attracted the attention of the king while with a royal hunting party in the forest of Senart. It was not however until after the death of Mme. de Châteauroux (1744) that she became openly the king's favorite. She accompanied Louis during the campaign of Fontenoy in May, 1745, and on her return was presented at court by the title of marchioness de Pompadour. At first she meddled but little in political affairs. She patronized learning and the arts, embellished Paris, and with the assistance of Voltaire and Bernis organized brilliant fêtes, trusting for influence to her personal charms and her power of amusing the king. Even after she had lost to a great degree her hold upon his affections, she retained her power by making herself necessary to his comfort. She soon undertook to save him from the fatigues of government. She interfered with the finances, made and unmade ministers, and favored by turns the Jansenists, the Quietists, the infidels, and the parliament, that she might have the support of all parties. Flattered by Maria Theresa, who sent her an autograph letter, and irritated by the sarcasms of Frederic II. on the *dynastie des cotillons*, she brought about the alliance of France and Austria against Prussia which resulted in the disastrous 7 years' war. In 1757, after the attempt of Damiens to assassinate the king, she was obliged to quit the court; but being recalled soon afterward, she caused the ministers D'Argenson and Machault, who had advised her dismissal, to be disgraced. Her influence upon military appointments was one of the chief causes of the ill success of the war. She recalled Marshal d'Estrées after the French victory of Hastenbeck, and prevented the recall of Soubise after the defeat of the allies at Rossbach. She dismissed the minister Bernis, who advised peace, and replaced him by Choiseul. But in Choiseul, to her dismay, she soon found a master. He assisted her indeed to procure the suppression of the Jesuits, but it soon became apparent that his power depended no longer on her favor. She died hated by the nation and little regretted by the king. Beside an annual income of nearly 1,500,000 livres, she had received the territories of La Celle, Crécy, and St. Remy; the châteaux of Aulnay, Brimborion, and Bellevue; and splendid establishments at Paris, Versailles, Fontainebleau, and Compiègne. She made a generous use of her wealth, gave freely to the poor, patronized inventors, artists, and men of letters, and made magnificent collections of works of art and curiosities. She drew and engraved with considerable skill. The *Mémoires* and *Lettres* published under her name are not authentic.

POMPEII, an ancient city of S. Italy, situated about 14 m. S. E. of Naples, and directly at the foot of Mt. Vesuvius. It is of remote origin, having been founded probably by the Oscans, and subsequently occupied by the Etruscans, Pelasgians, and Samnites, but is not mentioned in history previous to the conquest of Campania by the Romans in the 4th century B. C. The name has no connection with that of the Roman *gens Pompeia*, but is supposed to have been derived from the word *πομπεία*, a triumphal procession, from the tradition that Hercules celebrated the foundation of the city with pomp. During the social or Marsic war the inhabitants joined in the insurrection; but the city was spared by Sylla, who contented himself with dismantling its fortifications, and planting a military colony in the neighborhood. Soon afterward it became a favorite summer resort of Romans of wealth and rank, and is mentioned as such by Seneca and Tacitus, the former of whom calls it a "celebrated city." Cicero had a considerable villa there, in which he sought relief from the midsummer heats of Rome, and where he entertained Augustus and other distinguished guests. In A. D. 59, in consequence of a sanguinary affray in the amphitheatre with the neighboring people of Nuceria, the inhabitants were prohibited by the emperor Nero from exhibiting any gladiatorial or theatrical shows within the city for 10 years. Four years later Pompeii was visited by two earthquakes, occurring at an interval of a few months, by which many public buildings were thrown down and an immense amount of damage done; and it had not entirely recovered from the effects of these disasters when it was overwhelmed by the famous eruption of Vesuvius, Aug. 24, 79, which involved it and the neighboring towns of Herculaneum and Stabiæ in a common destruction. (See HERCULANEUM.) Thenceforward for nearly 17 centuries the city disappears from history, although the name seems never to have been wholly lost. A village constructed from its ruins subsequently arose upon the site; but after the destruction of this by the eruption of 472, the Campus Pompeius, as it was long called, remained until the middle of the last century an undisturbed and uninhabited plain. As if to baffle more completely the researches of archæologists, the eruption of 79 produced striking physical changes in the vicinity, and the sea, which formerly laved the walls of the city, is now upward of a mile from its site, while the neighboring river Sarno has been considerably diverted from its ancient course. Hence the geographer Cluverius, who investigated the subject in the early part of the 17th century, following the descriptions of ancient authors, was induced to locate Pompeii at a distance of several miles from its actual position. A few years previous the architect Domenico Fontana had carried an aqueduct over a large portion of the buried city, without having his attention aroused by the remains of temples and public buildings which must have been constantly encountered. In this instance the oversight is somewhat remarkable, as the superincumbent deposit of ashes and cinders had an average depth of not more than 15 feet, and a portion of the great theatre was still visible. For nearly a century and a half longer Pompeii remained undisturbed, and it was not until the exhumation in 1748 of several statues and other objects of antiquity in sinking a well that public attention, already awakened by the partial excavation of Herculaneum, was drawn to the subject. Charles III. of Naples ordered excavations to be prosecuted on an extensive scale, and in 1755 the amphitheatre was uncovered. His successors have continued the work from time to time with more or less activity, until, after the lapse of nearly 18 centuries from the date of its destruction, about a fourth part of Pompeii has been brought to light. The city thus partially exhumed, though probably at its most prosperous period never ranking above a second rate provincial town, is of incalculable importance from the insight which it has afforded into the domestic economy, the arts, and the social life of the ancient world. The light and friable character of the volcanic deposits which overlaid it has fortunately preserved from decay the objects of most importance to modern archæologists, and the interiors of private and public buildings have been found undisturbed save by the original owners, who in many instances returned after the eruption had subsided to search for such articles of value as could be easily removed, and also probably for the bodies of relatives or friends who were unable to escape. The latter supposition would seem to be proved by the fact that comparatively few skeletons have been discovered, whereas, according to Dion Cassius, the loss of life was considerable, notwithstanding the inhabitants were assembled in the amphitheatre at the time of the catastrophe, and could readily make their escape. As it is pretty well settled that successive eruptions have contributed to the deposit which now covers the city, such original excavations must have been comparatively easy.—Pompeii occupied within its walls, which have been traced throughout their whole extent, an irregular oval area about two miles in circumference. On the W. or sea side there are no traces of walls, and those remaining, though originally of great strength, being flanked at irregular intervals by massive square towers, appear to have been allowed to fall into decay many years before the destruction of the city. The workmanship of these indicates the Osco-Pelasgic origin of the city. Eight gates have been discovered leading to Herculaneum, Capua, and other places, that to Herculaneum being the most important and ornamental. The streets, which for the most part run in regular lines, crossing each other nearly rectangularly, are with some exceptions barely wide enough to admit the passage of a single vehicle, and everywhere the ruts of the chariot wheels are visible in the polygonal lava blocks which form the pavement. The widest does not exceed 30 feet in breadth, few are over 22 feet, and that leading from the gate of Herculaneum to the forum, and which must have been one of the chief thoroughfares of the city, has an average width of from 12 to 14 feet only, including the raised footpath on either side. In addition to the last named, 4 other main streets have been partially or wholly traced, with which a regular system of minor streets appears to have been connected. These thoroughfares, with a single exception, terminate in or traverse the westerly quarter of the city, which is the only part yet completely explored, and which, from the number and character of the public buildings found there, was undoubtedly the most important. The forum, situated in the S.W. corner, is the most spacious and imposing structure in Pompeii, and in its immediate vicinity are the chief temples, theatres, and other public buildings. It was enclosed on 3 sides by a Doric colonnade, which embraced an area 160 yards in length by 35 in breadth, and in its general plan as well as in its surroundings resembled the usual Roman structures of the kind. Of the buildings adjoining it, that known as the temple of Jupiter on the N. side is supposed to have been the most magnificent in the city, and its portico of Corinthian columns is perhaps the finest yet exhumed. On the E. side stood the pantheon or temple of Augustus, as it has been called; the Curia or Senaculum; the temple of Mercury; and a spacious house, called the Chalcidicum, which, as appears from an inscription, was erected by the priestess Eumachia. On the S. are 3 buildings supposed to have been courts of justice, and on the W. a basilica, a large temple profusely decorated with painting and commonly called the temple of Venus, and the public granaries and prisons. All of these afford striking evidences of the disastrous effects of the earthquakes of 63 and 64. The architecture, moreover, like that of most public and private edifices in Pompeii, is of a mixed character, the style, whether Greek or Roman, being frequently defective, and the attempts to unite different orders clumsy and tasteless. Other public buildings were the temples of Fortune, of Isis, of Neptune or Hercules, and of Æsculapius, the names of the two last being conjectural. That of Neptune is of pure Doric architecture, not unlike the temple of the same name in Pæstum, and is the oldest structure of the kind in Pompeii. S. E. of the forum, and at a distance of 400 yards, were the great or tragic theatre, and the lesser theatre or Odeum, both of Roman origin. The former, having accommodations for about 5,000 people, stood on a slight elevation, and was never completely buried by the ashes. In the S. E. angle of the city was the amphitheatre, an ellipse 430 feet by 335, capable of seating 10,000 spectators, which was about half the population of the city; and immediately N. of the forum were the *thermæ* or public baths, in an elegantly adorned and well arranged structure. A long quadrangular building S. of and adjoining the great theatre is supposed to have been the barracks of troops or of gladiators. Numerous implements of war have been discovered there, and in and about the building were 64 skeletons, probably of men forming the guard, who remained at their posts unmoved by the catastrophe; "a remarkable and affecting proof," it has been observed, "of the discipline of the Roman soldier." The domestic architecture of Pompeii is in keeping with that of its public buildings, a mingling of the Greek and Roman methods with respect to external features and internal arrangements, although in plan the houses are more Roman than Greek. They are for the most part small and low, few exceeding two stories in height, have little external ornamentation, and are well adapted to a people accustomed like the Pompeians to pass most of the day in the open air. The ground fronts of many of the finest are occupied by shops, the rents derived from which formed an important source of revenue to the inhabitants. The upper stories of private dwellings, being of wood with flat roofs, were speedily consumed by the heated ashes of the eruption; but as these portions of the house were generally used as store rooms or apartments for servants, their loss is of little consequence. The lower or ground apartments, in which the family proper lived, have fortunately escaped serious injury, and in many of these the daily life, habits, tastes, and even the thoughts of the occupants can be traced with almost positive certainty. Of the houses of the better description, the names applied to which are either those of the supposed possessor, or are suggested by his occupation, or by prominent objects of art found in them, the most important are the house of Sallust, one of the largest and most complete in its arrangement and adornment in the city; that of Pansa; that of the tragic poet, less distinguished for its size than for the variety and beauty of its paintings, most of which have been removed to the Museo Borbonico in Naples, and for the well known mosaic of the choragus instructing the actors; that of Meleager or the Nereids; that of Castor and Pollux, unsurpassed in magnificence and size, and equally ornamented within and without; that of the faun, or of the great mosaic, so called from the bronze figure of the dancing faun and the famous mosaic of the battle of Issus found there, and which contains the most beautiful mosaics yet discovered in Pompeii; and that of M. Lucretius, one of the latest yet uncovered, and rich in pictures, mosaics, vases, bronzes, ornaments, and coins. Outside of the gate of Herculaneum are the remains of two extensive suburban villas, called with little reason the villas of Diomedes and of Cicero, the latter of which, after the removal of its treasures toward the end of the last century, was again filled up with earth. The approach to the gate of Herculaneum, which passes in front of these structures, is lined on either side with tombs of considerable size and architectural pretension. Several of the houses above mentioned were evidently entered by their owners immediately after the subsidence of the first eruption, in search of valuables; and the most important paintings and objects of art discovered by excavation have been deposited in the Museo Borbonico. (See NAPLES.) As no buildings indicating poverty in the occupants have been discovered, it is doubtful whether Pompeii had any pauper population, or whether they inhabited a quarter of the city not yet excavated. Of late years the excavations have proceeded slowly, the annual amount appropriated by the late Bourbon government having barely sufficed for repairs and various incidental expenses; but under the government inaugurated in 1860 the work, it is said, is to be prosecuted with increased energy.—Detailed accounts of the results of the explorations in Pompeii will be found in Mazois' work, continued by Gau, *Les ruines de Pompéi* (4 vols. fol., Paris, 1812–'38); in Sir W. Gell's "Pompeiana" (1st series, 2 vols. 8vo., London, 1824; 2d series, 2 vols. 8vo., 1830); and in Breton's *Pompeia* (8vo., Paris, 1855). The most recent work on the subject is that of Overbeck (8vo., part i., Leipsic, 1856).

POMPEY. I. CNEIUS POMPEIUS MAGNUS, a Roman general and triumvir, born Sept. 30, 106 B. C., assassinated in Egypt, Sept. 29, 48. He was the son of Cneius Pompeius Strabo, a general of some repute and consul in 89, and first saw military service in the social or Marsic war, in which he fought under his father. During the struggle between Marius and Sylla, he sided with the latter, and in 87 aided in the defence of Rome against Cinna and Sertorius, the partisans of Marius. The triumph of Marius compelled him to remain for some time in obscurity; but when Sylla, after finishing the Mithridatic war, took up his march for Italy, Pompey, eager to ingratiate himself with the chief of his party, raised on his own responsibility 3 legions, with which he defeated the Marian general M. Brutus and effected a junction with Sylla. During the war which prostrated the Marian party in the Italian peninsula, he gained great distinction as one of Sylla's legates, and was rewarded with the hand of Æmilia, the step-daughter of Sylla. He next reduced Sicily, and in 81, crossing over to Africa, he overran Numidia, where the Marian party still held out against Sylla, and completely crushed them in a battle, in which their general Cn. Domitius Ahenobarbus and 17,000 Numidians were slain. Upon returning to Rome he was met by the populace with acclamations, and the dictator bestowed upon him the surname of Magnus, which was thenceforth borne by himself and his descendants. Not content with this distinction, he claimed a triumph, a thing unheard of for a man of equestrian rank who had filled no office of state, and which encountered the opposition of Sylla. The latter, however, in view of the fact that Pompey's army was encamped outside of the city, finally yielded; and the young general, who had not yet completed his 25th year, entered Rome in triumph in Sept. 81. Two years later Pompey again thwarted the wishes of Sylla by securing the election of M. Æmilius Lepidus to the consulship; but, true to the aristocratic party to which he had attached himself, he refused to aid the consul in repealing the constitution of Sylla, and when Lepidus in 77 marched upon Rome at the head of an army, he joined Catulus in defeating him. In the succeeding year he was sent by the senate to coöperate with Metellus Pius in the reduction of Spain, where Sertorius, the last and ablest general of the Marian party, continued to hold out against the aristocracy. Here he met an enemy with abilities equal if not superior to his own, as was evinced in their first encounter, which resulted in the defeat of Pompey. In an obstinate battle fought in the next campaign he was again worsted by his opponent, narrowly escaping with his life; and on another occasion he was routed by him, with the loss of 6,000 men. He received reënforcements from the senate, and for several years an uncertain struggle was maintained. But Sertorius having been assassinated by his rival Perperna, Pompey found little difficulty in bringing the war to a successful termination, and in 71 he returned with his army to Rome. Passing through northern Italy, he cut to pieces a body of 6,000 gladiators, who had escaped from the battle in which their leader Spartacus was overthrown by Crassus, and thus claimed the merit of finishing the servile war also. So popular was he now with the soldiery and the people that his demand for a triumph was willingly granted, while Crassus, who had in reality crushed the formidable revolt of Spartacus, received only an ovation. In the following year Pompey and Crassus entered upon the consulship, notwithstanding both were excluded by the laws of Sylla; and the former increased his popularity by restoring the tribunitian power, and instituting a reform of the judicial system. These measures however involved the severance of his former party ties, and thenceforth for many years he was the avowed enemy of the aristocracy. For two years after the expiration of his consulship he kept aloof from civil affairs, for which in fact he had little capacity; and in 67, after an obstinate resistance by the aristocracy, which at one time threatened to end in a civil war, he was appointed with unlimited and irresponsible power for 3 years commander-in-chief of an immense naval force destined to exterminate the pirates who infested the Mediterranean. He speedily cleared the sea west of Greece of the enemy, and sailing to the eastward annihilated their entire force in a great battle off Coracesium, on the coast of Cilicia. In the course of 3 months the war was completed, and the victorious commander, during his absence from Rome in 66, was on motion of the tribune C. Manilius invested by acclamation with the command of the war against Mithridates, a measure advocated by Cicero in his oration *Pro Lege Manilia*, and by Pompey's rival in after times, Caius Julius Cæsar. This commission was accompanied with a grant of unlimited control over the land and naval forces in the East, and with proconsular power in the whole of Asia as far as Armenia; so that Pompey now wielded the most extensive authority hitherto conferred by law upon a Roman citizen, with the exception of Sylla. The aristocratic party naturally looked upon him with more jealousy and distrust than ever, while in the estimation of the people he was the foremost man in Rome. In the summer of 66 he assumed the command of the army of the East, and pushing forward with rapidity surprised and totally defeated Mithridates in Lesser Armenia. For the next 4 years his career was one of uninterrupted success. All eastern Asia Minor was subjected to the Roman sway, and Armenia, the southern Caucasus, Mesopotamia, Media, Syria, Phœnicia, and Judæa were either made tributaries to the republic or were reduced to the condition of conquered provinces. In 63 Mithridates, a fugitive in the Tauric Chersonesus, after vain endeavors to unite the barbarous tribes of eastern Europe against Rome, put an end to his life; and Pompey, who had taken Jerusalem and was meditating new conquests in the remote East, led back his troops to the Euxine, and at Sinope honored the remains of his adversary with a royal funeral. Early in 62 he left Asia, and proceeding by slow marches reached Rome at the end of a twelvemonth, bringing with him an immense train of royal and noble captives, and an almost fabulous amount of eastern spoils. His third triumph, lasting two days, was celebrated in Sept. 61, and from that date is to be traced the decline of his fortunes. Almost immediately afterward he met with a rebuff from the senate, who, glad of an opportunity to affront a man of his importance and influence with the people, refused to ratify his measures in Asia, and to make an assignment of the lands he had promised to his veterans. This only widened the breach between Pompey and the aristocracy, and hastened the downfall of both. In this emergency Pompey found a friend in Cæsar, whose influence with the people had been steadily growing during the absence of the former in the East, and who was now plotting with consummate tact to supplant him in power. They mutually agreed to support each other in their prominent public measures; and at the instance of Cæsar, Crassus, a man formidable from his great wealth and aristocratic connections, was induced to join the coalition, which is known in history as the first triumvirate. In the succeeding year, 59, Cæsar entered upon his first consulship, and secured for Pompey the ratification of his acts in Asia, and also by his agrarian law enabled him to make good his promises to his soldiers. At the same time, to cement eir union more closely, he gave him his aughter Julia in marriage. Pompey now sur- endered himself to the pleasures of domestic fe, with little care for the machinations of is enemies, or regard for the welfare of his iends. Cicero, his panegyrist, was allowed go into exile; and only when his own life as threatened by the enemies of the orator d Pompey make an effort to procure his re- ll. In gratitude for this act Cicero pro- red for Pompey the office of *præfectus an-* næ for 5 years, with proconsular authority d the command of 15 legions. Notwith- anding he was enabled to cheapen the price f corn in Rome, he found that his influence as waning at home, and that he had grad- ally lost the confidence of all parties. Exas- erated by the attacks of Clodius, Cato, and hers of his enemies, who, he charged, were ting at the instigation of Crassus, he repaired 56 to Cæsar's winter quarters at Lucca, here he was reconciled to Crassus, and the iumvirate was ratified anew, the agreement be- g that Pompey and Crassus should be consuls uring the ensuing year and obtain provinces d armies, while Cæsar was to have his gov- rnment of Gaul continued for 5 years. Ac- ordingly, in 55, after some opposition, Pom- y and his colleague were inducted into office, d the former, pleased with the idea of se- uring the dictatorship, endeavored to regain e popular favor by an exhibition of gladia- rial shows and combats of wild beasts in a rge theatre he had constructed in the Cam- us Martius. The people were amused for e moment, but soon began to express their scontent that Pompey should send his le- tes to Spain, the government of which prov- ce he had secured, instead of conducting the ar there personally. At the same time it ecame apparent that Cæsar was gaining so apidly in influence with the people that a truggle between him and his rival must ensue. or two years after the expiration of his con- lship Pompey remained at home, and by ecretly abetting intestine feuds promoted a ate of anarchy in Rome, which compelled the nate to invoke his assistance. He was in- ested with supreme authority by being made le consul in Feb. 52, and soon restored com- rative order in the city. This may be con- dered his final rupture with the people and s reconciliation with the aristocracy, of whom e now became the acknowledged head. Va- ous measures were at once brought forward check the designs of Cæsar, whose influence ith the people by a lavish expenditure of oney was steadily increasing; and upon his nnouncing his intention to stand for the con- lship for the year 48, Pompey and the aris- cracy demanded that he should present him- lf in Rome as a candidate for the office. æsar naturally declined to place himself in e power of his enemies, but agreed to resign s office and command if Pompey would do e same. As this proposition was unpalatable to the senate, a decree was passed in Jan. 49, by which Cæsar was required to disband his army before a specified time, under penalty of being declared an enemy to the republic. Cæsar, accepting the challenge thus thrown down to him, immediately crossed the Rubicon and marched upon Rome. Pompey, infatuated by the possession of power, and confident of his capacity to raise any number of troops the exigencies of the state might demand, had taken no measures to provide against this movement; and when Cæsar with his veteran legions, trained in the wars of Gaul, was at the city gates, he found himself utterly unable to offer resistance, and with the consuls and the greater part of the senate and aristocracy fled to Brundusium. Being vigorously followed by his enemy, he crossed over to Greece, and at Dyrrachium, on the coast of Illyricum, assembled a numerous army, with which he awaited the approach of Cæsar. Early in 48 Cæsar arrived in Greece, with forces less numerous than those of his opponent, but greatly superior in discipline. He manœuvred in vain to draw Pompey from his position; the latter was bent upon weakening his enemy without risking a battle, and had he been allowed to follow out his plans might have escaped ruin. But the clamorous impatience of the Roman nobles and senators who filled his camp thwarted his purpose, and when Cæsar, after a severe check at Dyrrachium, was compelled through failure of supplies to direct his march into Thessaly, Pompey was urged against his better judgment to follow and give him battle on the plains of Pharsalus. His army was completely routed by Cæsar's veterans, and he himself, disheartened and bewildered by his defeat, fled with a few friends to Lesbos, whence he repaired to Pamphylia, where a number of his party with ships and troops joined him. Being advised to seek an asylum with the young king of Egypt, to whose father he had rendered signal services, he arrived off the coast of that country and disembarked in a small boat with a few attendants. The chief officers of the king, who were awaiting him on the shore, had determined, as a means of propitiating Cæsar, upon putting him to death; and as he was about to leave the boat Septimius, who had been one of his centurions and was now in the service of the king of Egypt, stabbed him in the back. The rest then drew their swords, and Pompey, seeing that resistance was hopeless, covered his face with his toga and was despatched upon the spot. His body was cast out naked on the shore, where it was buried by a freedman, and his head sent to Cæsar, who wept upon beholding it, and put his murderers to death. In private life Pompey was temperate and frugal, and was a kind and indulgent husband. It deserves to be mentioned to his credit that his immense wealth was honestly acquired, and that he was conscientious in the management of the public finances. He was married

5 times, his last wife, Cornelia, surviving him. II. Cneius, eldest son of the preceding by his 3d wife, Mucia, born between 80 and 75 B. C., killed in Lauron on the Spanish coast in 45. His first important military service was in the war between his father and Cæsar. After the battle of Pharsalia he was left in possession of a formidable fleet, and in 47 began to take active measures to renew the war. He collected an army of 13 legions in Spain, whither in the latter part of 46 Cæsar followed him. He was totally defeated in the desperate battle of Munda, March 17, 45, and shortly after was overtaken and killed at Lauron. He was naturally bold and passionate, and the death of his father aroused in him a ferocious implacability. III. Sextus, brother of the preceding, born in 75 B. C., killed at Miletus, Asia Minor, in 35. After the defeat of his brother at Munda he assembled a considerable force of fugitives and malcontents, with which he defeated Asinius Pollio, the Roman legate, and acquired possession of Bœtica and other portions of Spain. So formidable did he become, that it was proposed in the senate to make terms with him, and a vote was taken to allow him to return to Rome and to indemnify him for the confiscation of his father's possessions. The formation of the 2d triumvirate defeated this project, and Sextus, being now declared an outlaw, made a descent upon Sicily, which was speedily reduced to his sway. For several years he contented himself with harassing his enemies by cutting off their supplies of provisions from Sicily, and in 42 he defeated in the straits of Sicily a fleet sent against him by the triumvir Octavius. During the campaign of the triumvirs against Brutus and Cassius he remained inactive, but subsequently the vigilance of his fleet in intercepting the supplies of corn destined for Rome produced such a scarcity in the capital, that the populace rising in insurrection demanded that peace should be concluded with him. A treaty highly advantageous to Sextus was accordingly negotiated, but proved a mere delusion, none of the parties apparently being sincere in their professions. The war recommenced with signal advantages to Sextus, whose admirals in 38 twice defeated the fleets of Octavius; but again by his inactivity he let the moment for decisive action slip by, and quietly permitted his enemies to equip new armaments. In the summer of 36 three large fleets sailed from different points upon Sicily, but were so shattered by a storm that the attack proved abortive. With fatal infatuation Sextus again allowed Octavius to recover from this disaster, and in September of the same year the triumvir's fleet, commanded by M. Vipsanius Agrippa, completely defeated his own in a fight off Naulochus on the coast of Sicily. He fled with a few ships to Asia Minor, and, after vain endeavors to wrest the eastern provinces from Antony, was captured and put to death by the triumvir's legate, M. Titius.

POMPONIUS MELA. See Mela.

PONCE, Pedro, a Spanish Benedictine, born in Old Castile about 1530, died at the convent of Ona, in Old Castile, in 1584. He is believed to have been the first instructor of deaf mutes in articulation. Ambrosio Morales states that he taught two brothers and a sister of the constable of Castile, and a son of the grand justice of Aragon, who were deaf and dumb; and after some years they were not only able to write and read correctly, but to converse intelligently. One of them, who died in his 20th year, spoke and wrote Latin fluently. Another became a Benedictine, and, according to the testimony of Sir Kenelm Digby, conversed on religious and scientific subjects very freely, and without betraying his infirmity. Sir Kenelm's account of Ponce and his method of teaching is supposed to have been the means of calling the attention of Wallis and Holder, and perhaps also Dalgarno, to the education of deaf mutes. Ponce wrote a treatise in Spanish, now lost, in which he explained his methods, and laid down certain rules for the instruction of the deaf and dumb.

PONCE DE LEON, Juan, a Spanish discoverer, born in Leon, died in Cuba in 1521. He distinguished himself in several campaigns against the Moors of Granada, and, accompanying Columbus on his second expedition in 1493, became commander of the eastern province of Hispaniola. He made an expedition to Porto Rico in 1508, procured considerable gold, and on his return to Hispaniola obtained permission to raise money and men sufficient to subjugate the island; but before he set out he was removed and another commander appointed in his place. In 1509 he was reappointed, and finally reduced the island, which he governed with severity, till the family of Columbus again caused his removal. He was now an old man; but his love of adventure was still strong, and beside he had heard of the existence of a fountain which could restore youth and beauty; and confident of the reality of the fabled fountain, he fitted out 3 ships at his own expense, and on March 3, 1512, sailed from St. Germain in Porto Rico for the Bahamas, one of which group, called Bimini, was said to contain the marvellous fountain. Island after island was visited, the waters of every river, fountain, or lake were tasted, but no trace of Bimini or its wonderful stream could be found. Turning to the north-west, on Easter Sunday land was seen. It was thought to be an island, and from the magnificence of the vegetation and from the day of its discovery (Span. *Pascua florida*) it received the name of Florida. On April 8 he landed some miles N. of the present site of St. Augustine, and took possession of the country in the name of the king of Spain. He spent several months in cruising, doubled Cape Florida, sailed among the group called by him Tortugas, and finally returned to Porto Rico, leaving behind one of his followers to continue the search. In 1513 e arrival in Spain, where he was appointed overnor of Florida, on condition that he should olonize the country. The next year he re- eived the command of an expedition fitted out gainst the Caribbee Indians, which proved nsuccessful. Retiring to *Porto Rico*, it was ot until 1521 that, embarking nearly all his ealth in two ships, he proceeded to take pos- ession of his province. In Florida he was met y the natives with determined hostility, and n an attack made by them the Spaniards ere driven to their ships, and Ponce de Leon imself was mortally wounded, and died after is arrival in Cuba.

PONCE DE LEON, Luis, a Spanish lyric et, born in Granada in 1528, died in Madri- d, Aug. 23, 1591. He entered the Augus- tian order at the age of 16, became licen- iate in theology in 1560, and doctor of divin- y shortly afterward, and at the age of 34 btained a professorship of theology at Sala- anca. Ten years later he was made professor f sacred literature. For the benefit of some iends he made a version of the "Song of olomon" into Castilian; and the manuscript lling into the hands of his enemies, he was rought before the inquisition of Valladolid in 572, on a charge of Lutheranism, and of hav- g translated a part of the Scriptures into the ernacular without authority. After 5 years' prisonment he was reinstated in all his offices the university in Dec. 1576, beginning his first cture after so many years' intermission with e simple introduction: "As we remarked hen we last met." His original productions, hich stand at the head of Spanish lyrical etry, are few in number, and chiefly of a re- gious character. They were first published by s friend Quevedo in 1631. His most popular ose work was his *Perfecta casada*, or "Per- ct Wife," a treatise in the form of a commen- ry on portions of the book of Proverbs. mong his other prose works are the "Exposi- on of Job," and "The Names of Christ," nsisting of a series of eloquent discourses on e Saviour's character. He also translated e Eclogues and two of the Georgics of Virgil, out 30 odes of Horace, about 40 psalms, and ssages from the Greek and Italian poets. he best edition of his works is that of Madrid vols., 1804-'16). At the time of his death e had just been chosen head of his order, and as planning regulations for its reform.

POND, Enoch, D.D., an American clergy- an, born in Wrentham, Mass., July 29, 1791. e was graduated at Brown university in 1813, udied theology with Dr. Emmons of Franklin, as licensed to preach by the Mendon associ- tion in June, 1814, and was ordained pastor of e Congregational church in Ward (now Au- urn), Mass., March 1, 1815. He was dismissed 1828, to become the conductor of the "Spirit the Pilgrims," a monthly publication in the terest of orthodox Congregationalism then st established in Boston, and which bore an portant part in what is known as the "great Unitarian controversy." After editing 5 volumes of this work, writing himself more than half the articles published, he was called to the professorship of theology in the theological seminary at Bangor, Me., and inaugurated in Sept. 1832. He continued to discharge the duties of that position and of the department of ecclesiastical history until 1856, when he resigned the professorship of theology, to become "president, professor of ecclesiastical history, and lecturer on pastoral duties," which is the designation of his present relation to the institution. Dr. Pond's first publication, in 1817, was a review of a sermon against "Conference Meetings," by Dr. Bancroft of Worcester, Mass., which led to a reply and rejoinder. The same year he reviewed "Judson on Baptism," his review reaching two editions. In 1824 he published a volume of "Monthly Concert Lectures." Since that time he has published the following works: in 1827, a "Memoir of President Davies," and a "Memoir of Susanna Anthony;" in 1839, a "Memoir of Count Zinzendorf;" in 1841, a "Memoir of John Wickliffe;" in 1842, the "Morning of the Reformation;" in 1843, a "Review of Second Advent Publications," and "No Fellowship with Romanism;" in 1844, the "Mather Family," and "The Young Pastor's Guide;" in 1845, "The World's Salvation;" in 1846, "Pope and Pagan," a "Review of Swedenborgianism" (a new edition of which was issued by the American tract society, Boston, 1861), and "Plato;" in 1848, a "Life of Increase Mather and Sir William Phipps," and "The Church" (which reached a second edition in 1860); in 1849, a "Review of Bushnell's 'God in Christ';" in 1851, the "Ancient Church;" in 1856, a "Memoir of John Knox;" and in 1858, "The Wreck and the Rescue, a memoir of Rev. Harrison Fairfield." Dr. Pond has been an extensive contributor to the principal religious journals, and has written also many tracts and short articles for the weekly press.

POND, John, an English astronomer, born about 1767, died in 1836. He studied under Wales, astronomer to Capt. Cook's expedition, and at Trinity college, Cambridge. Settling at Westbury near Bristol, he made a series of observations from which he deduced that the quadrant then in use at Greenwich for the determination of declinations had changed its form since 1750, a result subsequently verified by measurement. In 1807 he removed to London, and in 1811 was appointed to succeed Dr. Maskelyne as astronomer royal. He subsequently devoted his attention chiefly to determining the places of the fixed stars. He invented the method of observing in groups, and was the first astronomer who advocated the now universal practice of depending upon masses of observations for all fundamental data. He retired upon a pension in 1835.

PONDICHERRY, a town on the Coromandel coast, and capital of the French possessions in Hindostan, 85 m. S. from Madras; pop. about

40,000. It is situated at the mouth of a small river accessible by vessels of light draught, and presents from the sea a rather imposing appearance. Previous to the war of 1756, during which it was destroyed by the English, it was one of the finest cities in India. The European quarter is well laid out along the sea shore, and is separated from the native town by a ditch crossed by several bridges. There are large bazaars, 2 churches, a lighthouse, several schools, and a college. The territory annexed to Pondicherry has an area of 107 sq. m. and a population (1856) of about 120,000. It is surrounded by the British province of South Arcot, and is not very fertile. There is no harbor, but vessels anchor on the open coast, where at all times a heavy sea rolls in, and the surf upon the shore is almost as dangerous as at Madras. The value of both imports and exports is not quite $1,000,000 per annum. The settlement was purchased by the French from the Bejapoor rajah in 1672. It was captured by the Dutch in 1693, but given up at the peace of Ryswick; and taken by the British in 1761, 1778, 1793, and 1803, but each time restored at the conclusion of hostilities. When last given up by the English, it was stipulated that no European soldiers should be landed at Pondicherry, and no fortifications constructed.

PONGO. See Orang-Outang.

PONIATOWSKI, the name of a Polish family of Italian origin. Joseph Salinguerra, a member of the Italian family of Torelli, settled in Poland, and there assumed the name of Poniatowski from the estate of Poniatow, belonging to his wife, who was the daughter of Albert Poniatowski and Anna Leszczynska. The following are the most distinguished of his descendants. I. Stanislaw, born in 1677, died in 1762. He attached himself to the fortunes of Stanislas Leszczynski and his protector Charles XII., accompanied the Swedish army to Russia, and was present at the battle of Pultowa (1709), after which he was sent as ambassador to Constantinople, and while there was skilful enough to involve the sultan in a war with Russia. After the death of Charles, he supported Augustus II., and by him was raised to several offices. Upon the death of Augustus he again joined the fortunes of Stanislas Leszczynski, was taken prisoner at Dantzic by the Russians, was afterward released, and was held in high honor by Augustus III. He wrote "Remarks of a Polish Nobleman on Voltaire's 'History of Charles XII.'" (the Hague, 1741). II. Stanislaw August, eldest son of the preceding, born in 1732, was elected king of Poland in 1764, and died in 1798. (See Poland.) III. Jozef Antoni, prince, and marshal of France, nephew of the preceding, born in Warsaw, May 7, 1762, drowned in the river Elster, Oct. 19, 1813. He entered the Austrian army, was in the campaign of 1787 against the Turks, and in 1789 was made a major-general in the Polish army. In the war against Russia in 1792 he commanded on the Bug, and when the king, his uncle, acceded to the confederation of Targovitza, Joseph left the service with most of the best officers; but when subsequently Kosciuszko raised the standard of revolt in 1794, he served under him as a volunteer, although in the campaign of 1792 Koscinszko had been below him in military rank. The command of a division was intrusted to him, with which he performed effective service during the two sieges of Warsaw, and after the capitulation of that city he went to Vienna. In 1798 he returned to Warsaw, then under the dominion of Prussia, lived upon his estates as a Prussian subject, and upon the occupation of that city by the French he joined their army, and during the campaign of 1807 commanded the Polish national army against the Russians. By the peace of Tilsit the duchy of Warsaw was created, and Poniatowski became its minister of war. In the war between Austria and France in 1809, he was compelled to evacuate the duchy, but invaded Galicia, and terminated the campaign by the occupation of Cracow. In the invasion of Russia in 1812 he commanded the Polish auxiliaries of the grand army. Just before the battle of Leipsic he was made by Napoleon a marshal of France. After that battle he was intrusted with the duty of covering the retreat of the French. The enemy had gained possession of the suburbs of the city, when with a small retinue he plunged into the deep stream of the Elster, in which he disappeared. His body was recovered 4 days after.

PONS, Louis, a French astronomer, born in Peyre, department of Hautes-Alpes, Dec. 24, 1761, died in Florence, Oct. 14, 1831. In 1789 he became connected with the observatory of Marseilles. He possessed such an uncommonly clear vision and excellent memory that a glance at a star enabled him to determine whether it belonged to the stars already catalogued or not. In 1819 he became superintendent of the observatory at Martia, in Lucca, and in 1825 of that of the museum at Florence. From 1801 to 1827 he had discovered 37 comets, and calculated the paths of many of them.

PONSARD, François, a French dramatist, born in Vienne, department of Isère, in 1814. He was sent to Paris in 1833 to study law, and in 1837 published a translation in verse of Byron's "Manfred." His first dramatic composition was the tragedy of *Lucrèce*. Rachel had refused to read it, and it had been declined by the committee of the Odeon theatre; but the manager of this theatre produced it. It had a great success, and received a prize from the academy. He subsequently produced other dramas with less success, and in 1852 fought a duel with Taxile Delord, a journalist, on account of some insinuations in reference to a public appointment. This affair was his inspiration in the comedy of *L'honneur et l'argent*, which, politely declined at the *théâtre Français*, was triumphantly produced at the Odeon. Ponsard was elected to the academy in 1855.

PONTCHARTRAIN, a salt water lake in the E. part of Louisiana, so called in honor of ount Pontchartrain, a minister of Louis XIV. he lake is about 40 m. in length from E. to ., by 24 in breadth from N. to S. It is conected with Lake Borgne on the E. by the igolets, a narrow winding strait, and with ake Maurepas on the W. by the bayou Manhac. Its S. shore approaches within 5 or 6 m. f New Orleans; and the bayou St. John, a mall tributary, extends into the suburbs of hat city. The lake is nowhere more than about 0 feet in depth, yet it is the medium through hich is carried on most of the coasting trade etween New Orleans and the eastern gulf orts. Steamboats and small vessels obtain ccess from the lake into the heart of the city y means of two canals, each terminating in an rtificial basin. The northern shores of the ake are more elevated than the southern, and fford sites for handsome country seats and laces of summer resort. Among these are the illages of Madisonville and Mandeville.

PONTE, DA. See BASSANO.

PONTE DELGADO, a town on the S. side f the island of St. Michael, one of the Azores, n lat. 37° 40′ N., long. 25° 36′ W.; pop. 22,000. t is tolerably well built and substantial, and is efended on the sea side by the castle of St. ras, and about 3 m. to the E. by the forts of an Pedro and Rosto de Cão. The harbor is shallow that vessels require to be loaded outide by means of lighters. Wheat, maize, and ranges are the chief exports.

PONTIAC, the capital of Oakland co., Mich., n Clinton river, and on the Detroit and Milwaukee railroad, 26 m. N. W. from the former; op. in 1860, 2,600. It has an active business, nd exports largely of wool, wheat, fruit, and utter. Beside the county buildings it contains number of manufactories, the river affording mple water power, 2 weekly newspaper offices, nd 7 churches.

PONTIAC, a North American Indian chief f the Ottawas, an Algonquin tribe, born about 712, killed in 1769. He was first known as n ally of the French. In 1746, at the head of body of Indians, mostly Ottawas, he successlly defended Detroit, then a French possesion, against the attacks of some hostile northrn tribes. He is believed to have led several undred Ottawas at Braddock's defeat in 1755; nd when an English detachment was sent nder Major Rogers in 1760 to take possession f the western posts that the French had reinquished by the treaty of Paris, it was met y Pontiac, who, though he claimed the terltory as his own, received the English commandant in a friendly spirit, and saw him safely o his destination at Detroit. The Indians at hat time were fond of the French, and hated he English; their discontent was increased by njudicious usage, and trivial conspiracies bean to be formed. Pontiac also became embittered, and finally determined to concentrate he hatred of all the western tribes in one great effort to drive out the English. At the end of 1762 he sent messengers to the different nations, proposing that in May, 1763, they should rise, massacre the English garrisons, and fall upon the frontier settlements. The plot was generally successful. Pontiac had reserved for himself the attack upon Detroit, but before it was made his intention was discovered. He then regularly besieged the place, and neglected no expedient that savage warfare could suggest to take it. To obtain food for his warriors he issued promissory notes, drawn upon birch bark and signed with the figure of an otter, which were all redeemed. After the siege had continued from May 12 until Oct. 12 it was raised, and the tribes generally sued for peace. But Pontiac was not yet subdued. He endeavored to stir up the Indians on the Miami and in other parts of the West, and applied for aid in vain to the French commander at New Orleans. He at last made a stand in the Illinois country, where for a time he had the active coöperation of the French fur traders; but even his more immediate followers fell away from him, and he then accepted the peace which the English offered. From this time he had no importance, and in 1766 he formally submitted to the English rule. He was killed by an Illinois Indian at Cahokia opposite St. Louis, while drunk.—See "History of the Conspiracy of Pontiac," by F. Parkman (Boston, 1851).

PONTIFEX, in ancient Rome, the title of a priest. The office of pontifex is said to have been created by Numa, and under him the pontifices were 4 in number, exclusive of the pontifex maximus, or chief priest. The pontifices were not attached to the worship of any particular divinity, but were a college of priests superior to all others, and superintended the whole public worship. In 300 B. C. the whole number was increased to 9, in 81 by the dictator Sylla to 15, and by Julius Cæsar to 16. The pontifices held office for life. Upon the death of a pontifex a successor was chosen, originally by the college of priests, but in 104 this election was given to the people by the *lex Domitia*. The college of priests had the superintendence of religion, kept the books of ritual ordinances, and were required to give information to any one who might consult them on matters of religion. It was their duty to guard against irregularity in the observance of religious rites, and to determine every thing in relation to burials, and how the manes of the departed should be appeased. Over all classes of the people they had the power of judicial decision and punishment in religious matters, could make new laws and regulations, and were themselves not subject to any court of law, nor responsible either to the senate or to the people. The pontifex maximus was the president of the college, and acted in its name. He was obliged to live in a *domus publica*, and was not allowed to leave Italy. This latter law was first violated in 131 B. C. and afterward was never very strictly observed.

A pontifex might hold any other office, civil, military, or priestly, provided it did not interfere with his pontifical duties. There are several instances in which the offices of pontifex maximus and consul were held in conjunction. The college of pontifices existed until the final overthrow of paganism, though it had retained in its latter years but very little of its ancient power or respect.

PONTIFICAL STATES. See PAPAL STATES.

PONTINE MARSHES, a low marshy plain in the S. part of the Campagna of Rome, extending along the Mediterranean coast from Cisterna to Terracina, a distance of about 25 m. Its breadth varies from 4 to 11 m., and its area is about 80 sq. m. These marshes are formed by the stagnation of the waters of the numerous streams which flow down the Volscian mountains or take their rise in springs at their foot, and are prevented from finding an outlet to the sea by the low level of the plain and the accumulation of sand upon the coast. Although there is little doubt that this tract of ground was of a later formation than the surrounding territory, the opinion of the Romans that it had its origin since the historic period is probably erroneous. This impression seems to have sprung from the belief that Mons Circeius was in the time of Homer surrounded by the sea, and was the island of Circe mentioned by that poet. Pliny preserves a tradition that these low grounds formerly contained 24 cities; but this is evidently false, as no traces of their site or even of their names can be found. The name of the marshes was derived from Suessa Pometia, a Volscian town somewhere on their borders, which about 500 B. C. disappeared from history, and the position of which is not now known. Various attempts were made by the Romans to drain the marshes, both for the sake of the land, and to prevent the miasma which was sometimes borne by the south wind as far as Rome itself. As early as 312 B. C. the Appian way seems to have been carried through this district, and along with it a canal from Appii Forum to Terracina. In 160 B. C. an attempt to drain the marshes was made by the consul Cornelius Cethegus; but, though this was apparently attended with success, the tract had so soon reverted to its original condition that its drainage was one of the public works projected by Cæsar, which however he did not live to execute. With the exception of temporary improvements, nothing was done by the succeeding emperors to accomplish this work until the reign of Trajan, who restored completely the Appian way. During the wars preceding the downfall of the Roman empire the marshes had been suffered to revert to their original condition, and Theodoric undertook the drainage with considerable success. But the commotions of the time soon caused them to be neglected, and they became as uninhabitable as ever, remaining so with scarcely any change until the reign of Pope Pius VI. Boniface VIII. had indeed caused the district about Sezzo and Sermoneta to be drained by a large canal; and in 1417 Martin V. had another canal, called the Rio Martino, dug to within a mile of the sea, when the project was abandoned at his death. The district was granted by Leo X. to the Medici, upon the condition of their draining it, and it remained in their hands 69 years, during which time scarcely any thing was done toward its improvement. A large canal, called the Fiume Sisto, was dug during the reign of Sixtus V.; but after the death of that pontiff in 1590 the dams gave way, and the country was again flooded. When Pius VI. became pope, he directed his attention to draining the marshes, and the work was begun in 1778, and completed in 1788. The line of the Appian way was in part restored, and the canal attributed to Augustus was again opened under the name of Linea Pia. It has been found almost impossible, however, to reclaim the waste land, although there is much under cultivation, and large pastures abound, where horses, cattle, and buffaloes graze. The district called Pomptinus Ager, often portioned out to Roman colonists, was probably the land bordering on the marshes, and not the marshes themselves.

PONTOPPIDAN, ERIK, a Danish antiquary, born in Aarhuus, Jutland, in 1698, died in Bergen in 1765. He was the son of a clergyman, and was graduated in divinity at the university of Copenhagen. After travelling as tutor with several young noblemen, he became professor of theology at Copenhagen in 1738, and bishop of Bergen in Norway in 1747. In 1730 he published a description of the geography, natural history, antiquities, &c., of Denmark, under the title of *Theatrum Daniæ Veteris et Modernæ*, and afterward treated the same subjects more fully in his *Danske Atlas eller kongen Riget Dænemark* (7 vols. 4to., Copenhagen, 1763–'74). Among his other works are: *Gesta et Vestigia Danorum extra Daniam* (1740); *Annales Ecclesiæ Daniæ* (1741–'52); *Glossarium Norvegicum* (1749); and *Det förste Forsög paa Norges naturlige Historie* (1752), which has been translated into English. He was the first to give an account of the kraken.

PONTORMO, JACOPO CARRUCCI, surnamed Il Pontormo, an Italian painter, born at Pontormo, Tuscany, in 1493, died in 1558. A pupil of Andrea del Sarto, he won the commendations of Michel Angelo and Raphael, whereupon his master from jealousy expelled him from his studio. He did not however fulfil the hopes of his admirers, and left but few historical pictures, the most valuable of which is the "Visitation of our Lady," in the Annunziata at Florence. In portraiture his works rank among the masterpieces of the Florentine school.

PONTOTOC, a N. co. of Miss., watered by the Tallahatchee and Yallobusha and branches of the Tombigbee river; area, about 900 sq. m.; pop. in 1860, 22,114, of whom 7,596 were slaves. It has an undulating surface and fertile soil.

e productions in 1850 were 667,612 bushels Indian corn, 110,871 of sweet potatoes, 82,181 l. of rice, and 9,017 bales of cotton. There are 2 grist mills, 6 saw mills, 2 tanneries, 2 ewspaper offices, 47 churches, and 576 pupils tending public schools. Capital, Pontotoc.

PONTUS, an ancient division of Asia Minor, mprised within the boundaries of the pres- t Anatolia. It derived its name from its uation upon the S. shore of the Pontus Eux- us, and was bounded E. by Colchis, S. by Ar- enia Minor, Cappadocia, and Galatia, and W. y the river Halys. Xenophon is the earliest thor by whom this district is called Pontus; had previously been designated by the names f the various tribes that inhabited it. Some f these tribes were extremely wild and savage, ut the Greek colonies established upon the oast as early as the 7th century B. C. gradu- lly spread culture and civilization. While the hole country was under the dominion of Per- a, and in the reign of Artaxerxes II. about the ginning of the 4th century B. C., Ariobar- anes conquered several of the Pontian tribes nd first established the country as an inde- endent kingdom. In the reign of Mithridates I. the kingdom acquired political importance, nd during the troubles following the death of lexander secured its independence. Under Mithridates VI. it was subdued by the Romans nd dismembered, the eastern part being given gain to its earlier savage owners, and the west- rn part annexed to Bithynia. A portion of his territory was subsequently made a sover- ignty under Polemo, and the whole became a Roman province, A. D. 67.

PONTUS EUXINUS. See BLACK SEA.

POODLE (*canis aquaticus*), the barbet or water dog. It has a high and round head, large cavity for the brain, expanded frontal sinuses, long ears, compact body, and rather short legs. The hair is long, curly, black, white, or the two mixed, sometimes with rufous marks. The large variety stands 16 to 20 inches high at the shoulders, and has coarse curled hair, often shaved to represent a miniature lion; the muzzle is short and prominent, and the tail is rather short and somewhat erect. It has long been known to fishermen and sportsmen as an excellent water dog; the sense of smell is exquisite, which gives it a remarkable power of tracing out the lost property of its master; it is strong, intelligent, and affectionate; it used to be a great favorite with soldiers on the continent of Europe, and many affecting anecdotes are on record of its fidelity to its living and attachment to its dead master. There is a diminutive breed, with longer, more silky, and curly hair, generally white, fit only for a lap dog; it is often the companion of unmarried and elderly ladies and childless wives.

POOLE, MATTHEW, an English divine and critic, born in York in 1624, died in 1679. He was educated at Emmanuel college, Cambridge, took orders, and in 1649 obtained the rectory of St. Michael le Quern, London, but resigned it upon the passage of the uniformity act in 1662. He was engaged in many of the controversies of his time, especially in those upon nonconformity, and wrote much in opposition to the Roman Catholic church. His last years were spent in Holland. His principal work is the *Synopsis Criticorum Biblicorum* (5 vols. fol., 1669-'76), a digest of the *Critici Sacri* (1660), presenting in a condensed form the views of 150 commentators.

POONAH, a district of British India, presidency of Bombay, bounded N. and E. by Ahmednuggur and Sholapore, S. and S. W. by Sattara, and W. by Tannah, extending from lat. 17° 53' to 19° 26' N., and from long. 73° 20' to 75° 10' E.; area, 5,298 sq. m.; pop. in 1855, 666,006. The district is included within the limits of the Deccan. The general elevation is about 2,000 feet above the sea, and the surface is intersected by numerous spurs and offsets from the W. Ghauts, which traverse the country in a S. E. direction, decreasing gradually in height till they sink into the plains in the Nizam's dominions. The principal rivers are the Beemah and its tributaries, the most important of which is the Neera. The climate is remarkably dry, the annual fall of rain being less than 20 inches. The soil is arid, and in many places water cannot be procured by sinking wells. Different kinds of grain and potatoes are cultivated, and cotton is grown to a small extent; but the country is almost entirely destitute of trees. The great Indian peninsular railway traverses the district. The inhabitants are chiefly Mahrattas, but there are a few Guzerattees and some Mohammedans.—POONAH, the capital, is situated at the junction of two tributaries of the river Beemah, 74 m. S. E. from Bombay; pop. 90,000. It was formerly the capital of the Mahratta confederacy, and the chief building in the town is the palace of the peishwa, now used as a prison, hospital, and lunatic asylum. The place is an important military station, and the British cantonments there are among the most extensive in India.

POOR, DANIEL, an American missionary, born in Danvers, Mass., June 27, 1789, died in Mampy, Ceylon, Feb. 3, 1855. He was graduated at Dartmouth college in 1811, and at the theological seminary at Andover in 1814. In Oct. 1815, he sailed for Ceylon in company with other missionaries, and reached Colombo in March, 1816. He took his station at Tillipally near Jaffna, studied the Tamul language, and in July, 1823, took charge of the mission seminary at Batticotta. In March, 1836, he removed to Madura, where 37 schools were soon opened mainly through his agency. He went back to Tillipally in 1841 on account of his health, and there labored until 1848, when he returned to the United States, where he spent 2 years working for the missionary cause. Returning to Ceylon in 1850, he settled at Mampy, where he resided until his death. He published several tracts, &c., in the English and Tamul languages.

POOR LAWS. See PAUPERISM.

POPAYAN, a city of New Granada, capital of the state of Cauca, and of a province of the same name, situated 6,000 feet above the sea on the river Cauca, in the great plain between the Cordillera of Quindin and that of Choco; pop. 20,000. It has a cathedral and numerous public edifices, and under the Spanish rule was a flourishing city; but its importance has been much reduced in consequence of the earthquake of 1834, and the unsettled state of the country. Its former trade in the precious metals has been in great measure destroyed, and its commerce is now confined chiefly to articles of produce. It is still, however, a place of importance from its position as a commercial mart between Quito and Bogota, and from the fact that a great commercial road nearly 1,000 m. long extends from it to Truxillo in Peru. Popayan was founded in 1537, being the first city built by Europeans in this portion of South America.

POPE. I. A S. co. of Ill., bordered S. E. by the Ohio river, which separates it from Ky., and intersected by Big Bay creek; area, 374 sq. m.; pop. in 1860, 6,742. It has a rolling surface, and the soil is a fertile sandy loam. The productions in 1850 were 223,592 bushels of Indian corn, 10,958 of oats, 2,352 of wheat, 2,937 lbs. of wool, and 13,922 of butter. There were 29 churches, and 570 pupils attending public schools. Capital, Golconda. II. A N. W. co. of Ark., bordered S. partly by the Arkansas river, which intersects the S. W. corner, and W. partly by Big Piney creek, and drained by Illinois bayou and other streams; area about 600 sq. m.; pop. in 1860, 3,855, of whom 2,440 were slaves. It has a hilly surface and fertile soil. The productions in 1850 were 202,830 bushels of Indian corn, 12,586 of sweet potatoes, 1,056 bales of cotton, and 3,780 lbs. of tobacco. There were 10 grist mills, 14 saw mills, 2 tanneries, 11 churches, and 326 pupils attending public schools. Capital, Dover.

POPE (Gr. παπα, father), a title applied by the eastern Christians to all priests, and in the West originally given to all bishops, but now restricted to the bishop of Rome. The Roman Catholics regard the pope as the legitimate successor of St. Peter and the visible head of the church, the invisible head being Christ. He was anciently elected by the people of his diocese, but is now chosen by the cardinals, a vote of two thirds being required to elect. On account of the union of temporal and ecclesiastical power in his person, it has long been an understood condition that he should be an Italian. (See PAPAL STATES.) The last pope of foreign birth was Adrian VI. (1522), a native of Utrecht. According to Roman Catholic writers, the bishop of Rome has always been recognized as the superior of all other Christian bishops; but Protestant historians date his supremacy generally from about the 4th century. We subjoin a table of the popes, according to the Roman *Notizie*, with the dates of the commencement of their reigns. The names printed in Italics are those of antipopes.

POPE, ALEXANDER, an English poet, born London, May 21, 1688, died at Twickenham, ddlesex, May 30, 1744. His father was a man Catholic, who, having acquired a small rtune as a linen merchant, retired on the revtion of 1688 to Binfield in Windsor forest. lexander inherited a crooked body and a kly constitution. His first education, to use s own words, was "extremely loose and disnted." Having taught himself to write copying out of printed books, he learned a tle Greek and Latin from a priest named Banter, and was then sent to school, first at Twyd, where he was flogged for lampooning his ster, and then at London, where he seems have studied little but Dryden, Spenser, and aller, Ogilby's translation of Homer, and ndys's translation of Ovid. Dryden was his ster in the art of poetry. He professed for m the warmest admiration, studied his works ntently, copied his style, and records as a morable incident, that when he was about 2 years old he had a glimpse of the great poet, en in the last year of his life. Soon after is Pope went home to Binfield, and entered a course of self-education which he continued with diligence until he was 19 or 20. e taught himself French, Latin, and Greek, rough the medium of translations, getting, as ld be expected, only a superficial knowldge of them, but devoting himself with more mplete success to various kinds of poetical mposition. The earliest of his pieces extant s "Ode on Solitude," written when he was out 12. From his 13th to his 15th year he as engaged upon "Alexander," an epic poem, of hich he had finished 4 books when he burned . In the mean time he composed a comedy nd a tragedy, which were likewise destroyed, nd gave promise of his satirical powers in ome "Lines to the Author of a Poem entitled uccessio" (Elkanah Settle), which were printed veral years later by Lintot in a volume of "Miscellaneous Poems and Translations" (1712). His imitations of some of the English poets, translations of the first book of the *Thebais* of Statius, and of Ovid's epistle from Sappho to Phaon and part of the "Metamorphoses," and the fables of "January and May" and the "Wife of Bath" from Chaucer, belong to nearly the same period; but none of his youthful compositions were published earlier than his 21st year, when they had probably received many corrections. About 1704 he was introduced by Sir William Trumbull to the veteran dramatist Wycherley. Pope "ran after him like a dog," and made under his auspices his first acquaintance with the coffee house wits of London. Wycherley in turn submitted his verses to the boy poet for correction, but the freedom with which Pope exercised his critical office soon resulted in a quarrel. Garth and Congreve were also among his early friends. In 1709 he established his position as the first poet of his time by the publication of his "Pastorals," written 5 years before. They appeared in the 6th volume of Tonson's "Poetical Miscellany," with the version of Chaucer's "January and May," and a translation of the episode of Sarpedon from the Iliad. He had already begun the "Essay on Criticism," which was published anonymously in 1711, and assailed by John Dennis with the most extravagant abuse. Addison praised it in the "Spectator" (No. 253) as "a masterpiece in its kind;" a commendation which, despite the faulty construction of the poem, nearly all subsequent critics have confirmed. In the next year Pope contributed to the "Spectator" the "Messiah, a Sacred Eclogue," one of the most popular and elevated of all his compositions. The first sketch of the "Rape of the Lock," a mere skeleton of what the poem afterward became, appeared in Lintot's collection of "Miscellaneous Poems and Translations" in 1712. It originated in a quarrel between two families of quality on account of the stealing of a lock of hair from the head of a reigning belle, and Pope was urged "to write a poem to make a jest of it, and laugh them together again." Whether it had the intended effect or not is doubtful, but its literary success at all events was such that the author determined to enlarge it, and in 1714 it was accordingly printed with the addition of the supernatural machinery and a dedication to Miss Arabella Fermor, the heroine of the piece. If not the greatest, it is the most highly finished and most delightful of his poems. About the beginning of 1713 he resolved to become a painter, and accordingly went to London, where for a year and a half he studied under Jervas, a pupil of Sir Godfrey Kneller. He had a strong natural taste for the art, but his bad eyesight was an insuperable bar to success; and after throwing away "three Dr. Swifts, two Lady Bridgewaters, a duchess of Montague, half a dozen earls, and one knight of the garter," and executing a few pieces which have had a better fate, he returned with fresh ardor to his more congenial pursuits. A descriptive poem on "Windsor Forest," which does not rank among his happiest productions, appeared in 1713, though the greater part of it had been written when he was only 16; and an "Ode for Music on St. Cecilia's Day," which is unfortunate in provoking comparison with the magnificent composition of Dryden on the same subject, was also published in this year. In the mean time Pope had found in a Roman Catholic family at Mapledurham near Binfield two friends with whom his name has always been associated, and who inspired some of the best of his letters and shorter poems. These were Teresa and Martha Blount, young ladies of good family and nearly his own age. Martha, the younger sister, was his devoted friend through life and his principal heir. Her intercourse with him did not escape the imputations of scandal, but it is now agreed that no imputations could be more unjust. Another of his friends was Gay; the publication of "Windsor Forest" led to his intimacy with Swift and Arbuthnot; and Steele, who was one of the first to appreciate his genius, introduced him to Addison. For the first performance of Addison's "Cato" (1713) he wrote a prologue which was not less popular than the tragedy itself; and when Dennis attacked the play he hastened to revenge his friend in a "Narrative of Dr. Robert Norris [a noted quack who pretended to cure lunatics] concerning the strange and deplorable Frenzy of J. D." Addison seems to have been displeased with Pope's officiousness, and took the pains to disavow all responsibility for the satire; but the friendly intercourse between the essayist and the poet was still uninterrupted, and Pope continued to write for the "Guardian," to which he had already contributed several papers. One of the best of these was a sarcastic parallel between his own pastorals and those of his rival Ambrose Philips, whom Steele in the same publication had pronounced the legitimate successor of Spenser.—Pope had so far been supported by a moderate allowance from his father; all his poetry together had not brought him £100. With the purpose of replenishing his purse, and encouraged by the advice of Addison, he now issued proposals for a poetical translation of the Iliad, to be published by subscription in 6 volumes at a guinea each. Swift exerted himself to promote the sale, and the young author's reputation was already so high that over 650 copies were subscribed for. Pope however was no master of Greek, and with all the help of various translations, had at first such "terrible moments" that he wished a hundred times somebody would hang him. But as the work went on his equanimity returned, the task became lighter, and he fell into the method of translating 30 or 40 verses before he got up, and working upon it the rest of the morning. "My usual method," he says, "was to take advantage of the first heat, and then to correct each book, first by the original text, then by other translations, and lastly to give it a reading for the versification only." In this way the work was finished in about 6 years, the first volume appearing in 1715 and the last in 1720. He had no cause to be dissatisfied with either the price of his labor or the reputation which it brought him. Beside the subscription money, he received from Lintot the publisher £200 for each volume; and his total receipts, according to Dr. Johnson, were £5,320, not reckoning the large sums paid by some of his subscribers in addition to the regular price. The king, for instance, gave him £200 and the prince of Wales £100. The life of Homer prefixed to the work was written by Parnell, and the information for the notes was gathered principally from Eustathius, by Broome, Jortin, and another whose name is not mentioned. Almost simultaneously with the publication of the first volume appeared a translation of the first book of the Iliad by Tickell. Pope says the nation was not more divided about whig and tory than the idle fellows of the feather were about the two translations. Addison gave the preference to Tickell, a preference not unreasonably suspected of springing from personal motives, and Pope even looked upon him as the real author of the verses which passed under Tickell's name. The result was an open quarrel with Addison, whom Pope afterward satirized in a piece which stands almost unrivalled in English poetry; it was first published in 1723, and again in 17[illegible], and was finally, with some changes, incorporated with the "Prologue to the Satires." He sent a copy of it to Addison before it was printed, and says "he used me very civilly ever after." During the progress of the Iliad Pope often visited London, gamed, drank, had "luxurious lobster nights," grew ashamed of business, railed at poor authors, frequented e drawing rooms of women of rank and hion, and the country seats of the nobility, ere his charming conversation made him ays welcome, and in a word set up for

The gayest valetudinaire,
Most thinking rake alive.

dy Mary Wortley Montagu made a particu- r impression upon him, and was one of his rrespondents. He soon tired however of a e of dissipation, and, the estate at Binfield ving been sold, removed with his parents to iswick, where he published a collection of poems (1 vol. fol. and 4to., 1717), in which t appeared his "Elegy to the Memory of Unfortunate Lady," and the "Epistle of oisa to Abelard," the most passionate of his orks. Of the concluding portion of this em, in which he refers to some future bard

Condemned whole years in absence to deplore,
And image charms he must behold no more,

writes to Lady Montagu, then at Constanti- ple: "You will find one passage that I can- t tell whether to wish you should understand r not." Soon after this, his father having ed, he purchased the lease of a villa on the ames at Twickenham, where in constructing rotto and decorating the grounds he found a axation from severer pursuits. When Lady ary returned to England (Oct. 1718), he rsuaded her to take up her residence near ickenham. But the ardor of his affection on cooled; they met seldom, and finally arrelled, and the lady to whom he had ad- essed the most impassioned love verses be- me the object of the coarsest of his satires. satisfactory explanation of their quarrel s ever been given; it is very commonly rified to a declaration of love by the poet lar circumstances which provoked the lady to an immoderate fit of laughter—a cause ite sufficient in Pope's case to account for e malignant hatred which he evidently bore er. While her influence was on the decline seems to have been smitten by the charms f another lady, "the mild Erinna, blushing her bays," with the idea of whom he says he came so mad as to steal her portrait and pass hole days in sitting before it. This is now ertained to have been Judith Cowper, after- ward Mrs. Madan, the aunt of the poet Cowper. —Pope's reputation was now so high that nson made him an offer to undertake an ition of Shakespeare, a task for which he d hardly a single qualification. The work as published in 1725 in 6 vols. 4to., and, ough abounding in faults of all kinds, had least the merit of pointing out the way r some future correction of the text. His nders and shortcomings were exposed by plodding author named Theobald, at first in treatise called "Shakespeare Restored," and terward in a formal edition, for which he as suitably rewarded in the "Dunciad." At e same time Pope had "undertaken" for ntot a translation of the Odyssey, the first volumes of which appeared in 1725, and the remaining 2 in 1726. Though he pro- fessed to have had the assistance of two friends (Broome and Fenton), he concealed the amount of this assistance, his own share comprising only 12 books, or one half the whole work. After deducting about £800 paid to his coadju- tors, his profits from the translation amounted to £2,885. Of this translation Bentley is said to have told him: "It is a pretty poem, Mr. Pope; but you must not call it Homer." On the other hand, as Dr. Johnson observes, he left in his versions "a treasure of poetical ele- gances to posterity," and "a series of lines so elaborately corrected and so sweetly modulated that the vulgar was enamored of the poem and the learned wondered at the translation." In 1727–'8 he published in conjunction with Swift 3 volumes of "Miscellanies," in which appeared his "Treatise of Martinus Scriblerus on the Bathos, or the Art of Sinking in Poet- ry," which gave rise to the "Dunciad." The "Treatise" was intended to form part of a larger prose work entitled "Memoirs of Mar- tinus Scriblerus," in which Pope, Swift, Ar- buthnot, Parnell, Lord Oxford, Atterbury, Con- greve, Gay, and others undertook to ridicule all the false tastes in learning. The project was abandoned in 1715 when the members of the Scriblerus club were dispersed, but to it we owe both the "Dunciad" and "Gulliver's Trav- els." The authors attacked in the "Treatise" retaliated in a number of publications, and even threatened Pope with personal violence. Thus provoked, he determined to crush the whole host of scribblers in one great effort of his genius, and, guided by the advice of Swift, who contributed largely to the prolegomena and notes, produced in 1728 that immortal poem "The Dunciad." The plan was bor- rowed from Dryden's "MacFlecknoe," and the hero at first was Theobald, who in a later edition was dethroned to make room for Colley Cib- ber. The sensation caused by the poem was immense. It was presented by Walpole to King George II., who was pleased to declare that Mr. Pope was "a very honest man." On the morning of publication the "dunces" be- sieged the printer's shop in crowds to prevent its sale, and failing in that held weekly clubs to concert hostilities. Dennis, who had re- ceived a conspicuous place in the satire, pub- lished several retaliatory pieces; but a few years later, when he was blind and in distress, Pope wrote a prologue to a play which was performed for his benefit. His triumph was now complete, and he could afford to be mag- nanimous.—The class of compositions to which Pope next applied himself, namely, his ethical poems, form the most refined and intellectual of his works. In 1731 appeared his epistle on "Taste," addressed to Lord Burlington (after- ward entitled "Of False Taste," and finally "Of the Use of Riches"), and in the next year an epistle to Lord Bathurst "On the Use of Riches." These are now known as the 4th and 3d of the "Moral Essays;" the 1st, to Lord numerous suckers from the roots render it objectionable. The wood is soft and nearly worthless. The narrow-leaved poplar (*P. angustifolia*, Torrey) is, according to Nuttall, the cottonwood noticed by Lewis and Clark in their expedition, and was seen frequently by him on the banks of the river Platte and its tributaries. The height of this species, which nearly resembles the balsam poplar, is from 60 to 100 feet; its smaller branches are round and smooth, and the leaf buds resinous; leaves ovate-lanceolate or acutely lanceolate, smooth above and slightly but obtusely serrate; the wood brittle and poor. It is almost the only tree occurring over wide extents of prairie. In the severity of the winter the Indians collect the branches to feed their horses, and the beaver selects them for his choice food; the resinous buds are also eaten greedily by a species of pigeon. The American aspen (*P. tremuloides*, Mx.) is a small, graceful tree, 20 to 40 feet high, with small and moderately spreading branches; the trunk has a whitish clay-colored bark blotched with very dark brown; the young shoots are of a polished bronze green, gradually changing to gray; leaves round, 2 inches long and of equal breadth, rather heart-shaped at base, abruptly acuminate, the border wavy toothed; the petiole very slender, as long as the leaf, and compressed laterally, from which arrangement the slightest wind agitates them. The wood is soft, fine-grained, light, and very perishable when exposed to the weather; the bark is excessively bitter, with a flavor similar to that of quinine. The tree is found in Canada as far N. as lat. 64°, and thence southward abundantly, and as far W. as the Rocky mountains. The large-toothed aspen (*P. grandidentata*, Mx.) is a tall, erect tree, covered with a smooth bark of a light greenish gray color; the branches are small, and the head is not very broad; the leaves, borne in tufts at the ends of the branches, are roundish, with large, irregular, sinuate teeth; smooth on both sides, but paler beneath; the petioles slender, compressed laterally, two thirds as long as the leaves. It is common in woods from New England to Pennsylvania, Wisconsin, and northward. The wood has been employed in various ways in the arts and used as a fuel, burning like pine when dry. The American black poplar (*P. betulæfolia*, Pursh) is regarded as a variety of the European black poplar, being first noticed in this country by Michaux on the banks of the Hudson river, and still to be found in the neighborhood of Hoboken, N. J., and seldom elsewhere in the United States.—The common black poplar or black-barked poplar is the *P. nigra* of Linnæus, belonging to Europe, growing wild from Sweden to Italy, on the banks of rivers and in moist woods, and rising to the altitude of 50 to 80 feet, with an ample head and numerous branches. The bark is ash-colored, and becomes deeply furrowed with age; the leaves, slightly notched upon their edges, are pale green, the petioles yellowish. The aments appear in March and April; those of the barren flowers are of a dark red color and produce a striking effect; the capsules are round and the seeds enveloped in a beautiful white cotton. The wood is soft, yellow, and fibrous, and is employed in making packing cases, and as it never splinters it is very useful for turning into bowls, trays, and such wares; it is an indifferent fuel; its bark is used in Russia in preparing morocco leather; the resin of the leaf buds is esteemed for healing properties, and bees are fond of the flowers. The white poplar or abele tree (*P. alba*, Linn.) is native of most parts of Europe, growing in moist soils and reaching the height of 80 to 90 feet. It is conspicuous for its singular, lobed leaves, which are dark green above and very white beneath. It is a popular ornamental tree in streets, cemeteries, and public squares, but its propensity to throw up suckers from the roots renders it somewhat objectionable where neatness is required. For planting out in poor and thin soils and in sandy areas, especially near the sea coast, this very disposition to spread rapidly over the soil renders it worthy of attention. There are numerous varieties, but the principal one is the hoary poplar (*P. canescens*, Smith), which differs in a roundish, deeply waved foliage, cylindrical aments, and 8 stigmas in the fertile flower; the bract is also more deeply and regularly cut. Its wood is adapted for fuel, and ranks highest of all the European poplars. The trembling poplar or European aspen (*P. tremula*, Linn.) is a rapidly growing tree of middle size, with a clear, straight trunk, and smooth bark, becoming gray and cracking with age; the branches, which are few, become pendulous; the young shoots are tough, pliant, and of a reddish color; the flowers appear early; petioles compressed; leaves roundish ovate or nearly orbicular and toothed, at first downy, but at length smooth on both sides. This species grows with great rapidity, being fond of wet soils and occurring in widely separate regions of Europe and Asia. The wood is tender and white, and employed by turners, engravers, cabinet makers, &c., and also used for burning into charcoal; its bark is employed for tanning; the leaves, either green or dry, are eaten readily by cattle and sheep. It is prized as an ornamental tree, especially in landscape gardening, and many superstitions are attached to the peculiarity of its trembling leaves when moved by the slightest breezes. The Lombardy poplar (*P. dilatata*, Aiton) is well known and readily distinguished by its tall, narrow form and tapering proportions. It has been considered as indigenous to Italy, particularly to the banks of the Po; but its native country is Persia, and it is found growing wild in the Himalaya. It was probably introduced into Italy from Persia; no mention is made of it by the Roman agricultural writers. Both in Europe and America its principal use seems to have been that of planting by canals and in rows along avenues, public squares, and roadsides. Among round-headed trees it groups well, and makes a fine contrast by its graceful and cypress-shaped outline. The Lombardy poplar has been known to grow 100 to 120 feet high, but it is not usual to see such specimens in this country. It is spoken of for its beauty on its native plains in the East. It flowers early in the season; the aments of barren blossoms are of a rich deep crimson, but they are seldom noticed, as they grow upon the uppermost branches. It was once a favorite in the United States, having been introduced about a century since, but is much out of favor now. Its wood is small in quantity in proportion to the size of the tree, and is nearly worthless.—The poplars are all easy of cultivation, increasing readily from suckers and cuttings. The wood of several species communicates various dyes to wool.—The term poplar is applied to the tulip tree (*Liriodendron tulipifera*), a noble and useful tree with which the true poplars have no affinity.

POPOCATEPETL (Nahuatl or Aztec, *popoca*, to smoke, and *tepetl*, mountain), or VOLCAN GRANDE DE MEXICO, a volcano situated about 30 m. S. W. of the city of Mexico. It has an elevation of 17,720 feet, or 1,946 feet higher than Mont Blanc, while the plain from which it is viewed is itself 7,000 feet above the level of Lombardy. It is connected with the volcano of Iztaccihuatl by a high ridge, which, at the pass of Ahualco, is 10,520 feet above the sea, and sometimes covered with snow. It was by way of this pass that Cortes, accompanied by 6,000 Tlascalan Indians, executed, in Oct. 1519, his bold march from Cholula to Tezcuco and Mexico. Popocatepetl was at that time in a state of extraordinary activity; and Cortes relates, in one of his letters to Charles V., that, wishing to discover whence proceeded the volumes of smoke which rose from the mountain, he chose 10 daring men among his companions to climb to its summit, under the lead of Diego de Ordaz, who boasted of having accomplished this feat, and was in consequence permitted by the emperor to emblazon a flaming volcano on his escutcheon. But Cortes states expressly that no one could reach the top of the mountain, in consequence of the great quantities of snow which covered it. He subsequently sent others on the same errand, and in 1522 one of them, Francisco Montaño, not only reached its top, but had himself let down into its crater by ropes to the depth of 70 or 80 fathoms. After a lapse of more than 300 years, the brothers Frederic and William Glennie in 1827 reached its summit and determined its altitude barometrically. They were followed by Samuel Birckbeck in Nov. 1827; by Baron von Gerolt, present minister of Prussia in the United States, in 1834; and on April 11, 1848, by Capt. Charles P. Stone and 5 other officers of the U. S. army then in Mexico. They observed several cones of eruption in the crater, from which proceeded periodical discharges of sulphurous vapors and cinders, of which the larger masses constantly fell back into the crater. A variable column of smoke is now visible from the mountain, but no luminous emanations. The years 1519, 1520, and 1540 alone seem to have been distinguished by igneous eruptions.

PÖPPIG, EDUARD, a German traveller and naturalist, born in Plauen in 1797. He finished his education at the university of Leipsic. In 1822 he went to Cuba, afterward visited the United States, travelled over Chili and Peru, went down the river Amazon, and in 1832 returned to Germany with botanical and zoological collections, and published an account of his travels and of his botanical researches. Since 1837 he has been professor of zoology in the university of Leipsic.

POPPY (*papaver*), the name of annual, rarely perennial, flowering plants, belonging mostly to the old world, and chiefly remarkable for producing in one species the drug known in commerce and medicine as opium. The species are herbs with a milky juice, fibrous roots, and round stems having imperfect nodes; alternate, simple or incised leaves, and nodding flower buds; sepals mostly 2, petals mostly 4; stigmas united into a flat crown of 4 to 20 rays resting on the summit of the ovary; fruit a capsule, short and turgid, with numerous many-seeded placentæ, opening by chinks under the edge of the stigma. The species, about 20 in number, are seldom seen in America except in gardens. The corn poppy (*P. rhœas*, Linn.) has a hairy stem, hispid, pinnate and bipinnate leaves, small scarlet flowers, and a smooth globose capsule. It is a common weed in the corn or grain fields of Europe; its flowers have a tendency to become multiplex-petalled and to assume a diversity of colors, rendering the varieties attractive annuals for the flowering garden. The common field poppy (*P. dubium*, Linn.) is seen in some parts of Pennsylvania and southward, having a stem clothed with slender spreading hairs, leaves pinnately dissected, the segments often incised and decurrent, the sepals hairy, the petals of a light scarlet, and the capsule smooth and obovoid-oblong. It is conjectured that it may become troublesome as an introduced weed unless attended to. The naked-stemmed poppy (*P. nudicaule*, Linn.) is a hairy perennial with pinnatifid leaves and very long peduncles bearing yellow flowers. It is found wild in Labrador and arctic America. The oriental poppy (*P. orientale*, Willd.) is a native of the Levant, and the bracteate poppy (*P. bracteatum*, Lindley) occurs in Siberia; they are both perennial species, with large, rough, pinnate-serrate foliage; the scape is long and 1-flowered, the sepals bristly, the petals large and of a brilliant reddish scarlet; the whole contour of the plants produces a great effect in the garden border.—The opium poppy, a native probably of Asia Minor, has a tall, annual stem; oblong, glaucous, smooth leaves, embracing the stalk; pure white petals, and a smooth globular capsule. There are two varieties, sometimes regarded as distinct species, viz.: the *P. somniferum*, with red, sometimes white flowers, and black seeds in globose capsules, known as the garden poppy; and the *P. officinale*, with pure white flowers and white seeds in ovate-globose capsules, the chinks under the stigma being obliterated. Both of these kinds are cultivated and employed in obtaining opium. When the white-flowered species or varieties become multiplex-petalled, they are very ornamental in the garden, especially such as have crimson stripes and lines upon a pure white ground. If care is taken to save seed from the best flowers, destroying all the inferior and single ones, these peculiar traits can be secured; and when the choicer sorts are sown in patches in rich soil, they should be very carefully thinned, and subsequently on coming into blossom the capsules should be cut off as the petals fall, in order to prolong the blooming. The opium poppy in India is sown in winter, and its products secured before the intense heat comes on. The soil is highly manured and copiously watered, for even the condition of the dew affects the quantity of opium produced. (See Opium.) The poppies are employed in other ways, the petals of the corn poppy being made into a red sirup, and the leaves of the rough poppy (*P. argemone*, Linn.) and of the *P. rhœas* have been used as a pot herb. The seeds of all the species are very numerous, and abound in a bland, sweet, and nutritious oil, not inferior to that obtained from the olive; the marc or cake is fed out to cattle or used as food for poultry. The seeds of the corn poppy are employed in Poland and Russia to make porridge, or for gruel, or as an ingredient in soup.—The poppy is the type of the natural order *papaveraceæ*, which according to Endlicher consists of annual or perennial herbs, rarely shrubby, with simple or occasionally underground tuberous roots; watery, milky, and often yellow juices; round stems bearing leaves and scapes; sessile, often petiolated, alternate leaves, the upper sometimes opposite, simple or compound, more or less divided, very rarely entire; perfect, regular flowers; calyx of 2 or 3 leaves, valvate or imbricate, caducous; corolla with its petals inserted on the receptacle, deciduous and imbricate in estivation, irregularly plicate or plane, the corolla sometimes wanting; stamens inserted on the receptacle, indefinite, multiseriate; stigmata connate; fruit mostly dry; seeds numerous. To this order belong some of the most showy flowers. The Welsh poppy (*meconopsis Cambrica*, Viguier) is remarkable for its yellow blossoms, and is to be met with in botanic gardens. The horn poppy (*glaucium luteum*, Scopoli) has a smooth stem, repand leaves, a roughish warted capsule, and large, numerous, showy flowers, which contrast finely with the glaucous foliage. It is found upon the sea coasts of England, and in waste places in the southern states. The prickly poppy (*argemone Mexicana*, Linn.) is a tall showy plant, with prickly foliage and a yellow juice; the flowers pale yellow or white. Some garden varieties of it with very large and delicate white flowers are very ornamental. The two species of the Californian poppy (*chryseis Californica* and *C. Douglasii*, T. and G.), elegant, low, spreading plants, with a fine-cut, glaucous foliage, and brilliant golden or orange-colored flowers produced throughout the entire summer, are much prized for bedding out in the garden. We have seen the former in a depauperated form becoming an adventitious weed. The bloodroot (*sanguinaria Canadensis*, Linn.) is remarkable for its early and pure snowy white flowers, and its crimson-orange colored juices of intense bitter taste, useful in medicine; and when introduced into the flower borders it vies with the crocus in the sunny days of spring. The *dendromecon rigidum* (Bentham) is a branching, glabrous shrub, with rigid, coriaceous foliage, and large yellow, papaveraceous flowers, found on the summits of the mountains of California.

PORCELAIN. See Pottery and Porcelain.

PORCELAIN CLAY. See Clay.

PORCUPINE (Lat. *porcus*, a hog, and *spina*, a thorn or spine), the common name of the sub-families *cercolabina* and *hystricina*, the most highly organized and widely distributed of the rodent family of *hystricidæ*. The former is confined to America, and the latter is spread over the old world. In both sub-families the clavicles are nearly perfect, attached to the sternum but not to the scapula; the infraorbital foramina are very large; the frontals very broad; the malar bones destitute of an angular process on the lower margin; the molars $\frac{4-4}{4-4}$; the dorsal vertebræ usually 14, and the lumbar 4; feet short; body more or less armed with spines or quills, capable of erection by the subcutaneous muscles.—The *cercolabina* live almost entirely in trees, and their feet have generally only 4 nearly equal toes, with long, compressed, and curved claws; there are sometimes 5 toes on the hind feet; the soles are thickly studded with small flattened warts; the skull short and broad, with a minute lachrymal bone forming no part of the lachrymal canal; the palate between the molars is on a lower level than the anterior portion; the molars converge in front, and are distinctly rooted, each having a fold of enamel on either side, the worn crown presenting 2 deep transverse cavities surrounded by enamel; incisors small: anterior and posterior clinoid processes wanting. This sub-family contains the genera *erethizon* (F. Cuv.), *cercolabes* (Brandt), and *chætomys* (Gray). The genus *erethizon* has a non-prehensile tail, short, thick, flattened, covered at the base above with hairs and spines, and on the under side and at the apex with stiff bristles; nostrils close together; feet short and broad: toes 4 or 5, with long curved claws; hind feet with a distinct inner toe with claw, without any projecting semicircular lobe on the inner side; upper lip slightly notched, but with no naked mesial line; body stout and covered with a long and dense fur from which the spines project; limbs short and strong. The best known species is the Canada porcupine (*E. dorsatus*, F. Cuv.), about 2½ feet long, weighing from 20 to 30 lbs.; it appears larger than it really is from the length of the hair and spines; the fur is generally dark brown, soft, woolly, and grayish next the skin, coarse and bristly in some parts, 6 or 7 inches long on the back, the coarse hairs usually with dirty white points, giving to the whole a hoary tint; the spines, more or less hidden by the fur, and abundant on the upper surface of the head, body, and tail, are 2 or 3 inches long, white with dark points; the tail is about 10 inches additional to the above length; the incisors deep orange. It is a very clumsy animal, with back much arched, snout thick and tumid, ears short and round, and tongue rough with scales. It is found between northern Pennsylvania and lat. 67° N., and to the E. of the upper Missouri river. It is an excellent though a slow climber; it is not able to escape its enemies by flight, but cannot be attacked even by the largest carnivora with impunity; dogs, wolves, the lynx, and the cougar have been known to die from the inflammation produced by its quills; these are loosely attached to the skin and barbed at the point, so that they easily penetrate, retain their hold, and tend continually to become more deeply inserted; when irritated it erects its quills, and by a quick lateral movement of the tail strikes its enemy, leaving the nose, mouth, and tongue beset with its darts; it has no power of shooting the quills. The food consists of vegetable substances, especially the inner bark and tender twigs of the elm, basswood, and hemlock; it seldom quits a tree while the bark is uneaten, except in cold weather, when it descends to sleep in a hollow stump or cave; as it kills the trees which it ascends, its depredations are often serious. The nest is made in a hollow tree, and the young, generally two, are born in April or May. It is almost as large as a beaver, and is eagerly hunted by the Indians, who eat the flesh, and use the quills to ornament their moccasons, belts, pouches, bags, baskets, and canoes, for which purpose they are often dyed with bright colors; it is very tenacious of life; it does not hibernate, as the European porcupine is said to do. This animal shows admirably that the quills are only modified hairs, as it presents quills on the back, spiny hairs on the sides, and coarse bristly hairs on the under surface, passing into each other in regular gradation. The yellow-haired porcupine (*E. epixanthus*, Brandt) is smaller than the preceding; the color is blackish brown, the long hairs of the body tipped with greenish yellow; the anterior molar, as in the other, is considerably larger than the rest; it is found W. of the Missouri to the Pacific ocean.—In the genus *cercolabes*, which includes the tree porcupines, the body is similarly armed with spines and spiny hairs; the tail is long and prehensile; all the feet 4-toed, with long and curved nails, the hind feet having each a rudimentary inner one, a small nailless tubercle, and being with the palm much expanded by a semicircular lobe on the inner side; the soles are rough and naked, the claws long, and the hind feet so articulated that the soles are directed inward; the lobe can be bent inward, being supported by several bones, some supernumerary; the tail is thick and muscular at the base, slender and bare above and prehensile at the end, the upper surface being applied to the branches, and the tail coiled in a direction opposite to that of the monkeys of the same country. The muzzle is very movable, hairy, thick, and obliquely truncated; the eyes small but prominent; ears small and sparingly clothed with hair; the incisors are narrow. They emit a disagreeable odor, somewhat like that of garlic; the food consists of fruits, leaves, and tender bark; they are usually seen singly, and sleep during the heat of the day, feeding at morning and evening; they are harmless, easily reconciled to captivity, but with very little intelligence. They inhabit America, from Mexico to Paraguay, living on trees, on which they are expert but slow climbers. The Brazilian tree porcupine (*C. prehensilis*, Brandt) is 16 to 20 inches to the base of tail, the latter nearly as much more. It is abundant in Guiana, Brazil, and Bolivia, and feeds on the fruit of the palms. In the Mexican tree porcupine (*C. Novæ Hispaniæ*, Briss.) the general color is black; the spines are nearly all hidden by the fur, yellowish or whitish with black points; it is about 18 inches long, with a tail of 14; it inhabits the temperate mountain regions of eastern Mexico, between 2,000 and 4,000 feet above the sea. Other species are described in vol. ii. of Waterhouse's "Natural History of the Mammalia" (London, 1848). Dr. Lund describes from the caves of Minas Geraes in Brazil two species of fossil tree porcupines, one of which he believes to have been as large as the peccary.—The sub-family *hystricinæ*, or the old world porcupines, dwell on the ground, living in burrows or caves in the rocks; they have 5 toes on all the feet, and the soles are naked and smooth; the skull is elongated, with a distinct lachrymal bone partly enclosing the lachrymal opening; molars semi-rooted and in parallel series, those of the upper jaw with one internal fold of enamel and 3 or 4 externally, soon assuming the form of small isolated areas; lower molars with the folds reversed; the whole palate is on the same level and the ethmoid processes are distinct; the upper lip is divided by a vertical groove. They are found in S. Europe, middle and S. Asia, and Africa. In the genus *hystrix* (Linn.) the tail is short, and the hinder part of the neck is armed with long cylindrical spines or quills; the inner toe of the fore feet is very short, with a small blunt nail; there are 5 fleshy pads on the fore, and 6 on the hind soles. The crested or common porcupine (*H. cristata*, Linn.) is found in S. Europe, where it has come from N. and W. Africa; it is about 28 inches long, the tail about 8 more; the muzzle is large and obtuse, sparingly clothed with small dusky hairs, with scattered longer and coarser ones on the upper lip; anterior and under parts and limbs with spines not more than 2 inches long, with which are mixed some coarse hairs; crest of numerous very long bristles, extending from the crown to the back, some 16 inches long, and curving backward; hind parts of the body and tail covered with quills, some slender and flexible, 12 to 16 inches long, others shorter, stouter, and very sharp; a few on the tip of the tail are hollow, generally open and truncated at the end, and supported on a very slender stalk about ¼ inch long. The prevailing color is brownish black, with a white band on the fore part of the neck; the longest quills have the terminal 5th white, and the rest variously ringed black and white; bristles of crest dusky with long white points, some all dirty white; feet black; the quills vary considerably in color, but are generally grooved with several delicate longitudinal channels. The skull may be at once recognized by the great size of the nasal bones, the development of the nasal cavity, and the highly arched upper surface. This is the *porc-épic* of the French, the spiny pig, so called from its heavy pig-like look and its grunting voice. It lives in rocky crevices or in burrows, becoming torpid in winter; the food consists of various vegetable substances, and its flesh is well flavored; it can erect its quills at pleasure, but cannot discharge them; beside its grunts, it makes a rattling noise by shaking the tuft of hollow quills on the tail; it also strikes the ground with its feet like the hares. The Nepaul porcupine (*H. Hodgsoni*, Gray) has no crest, and is covered chiefly with spiny bristles with long hair-like points, and the quills are rather black than white; it is very abundant in the sub-Himalayan region, and very mischievous, digging up potatoes and other tuberous and root crops; it is monogamous, and has 2 at a birth; the flesh is very delicate, and is eaten by all classes, even by the high caste Hindoos, according to Hodgson; it is easily tamed and breeds in captivity, and it is considered lucky to have a family about stables. Fossil bones of this genus have been found in Italy and India.

PORCUPINE ANT-EATER, the popular name of the *echidna* (Cuv.), a genus of marsupial mammals of the section *monotremata*, inhabiting Australia and Tasmania. The snout is long, slender, and naked, and the tongue protractile, very long, and slender, as in the ant-eaters proper; the opening of the mouth small; the upper part of the body covered with spines and hairs intermixed; legs short and powerful; all the feet with 5 well developed toes with large nails, the fore feet formed for burrowing, and the hind feet in the male with a horny spur as in the ornithorhynchus; tail very short and hidden by the spines. The best known species, the *E. aculeata* (Shaw), is about a foot long, with a stout body, spiny above, and the head, limbs, and lower parts with brownish black coarse hair; inner toe of the hind feet with a broad rounded nail, the others with long curved claws, that of the 2d very long. It is considerably larger than the common hedgehog, is powerfully built, and especially adapted for burrowing. The food consists of ants and other small insects, which it captures like the ant-eaters with its tongue, by means of a viscid matter secreted by 2 large submaxillary glands extending from behind the ear to the fore part of the chest; there are no teeth in the jaws, but the palate is armed with several rows of horny spines directed backward, and the upper surface of the tongue is furnished with numerous small corneous warts. The skull in shape has been compared to the half of a pear cut lengthwise, being 4 inches long by 1¾ wide at the posterior portion, ending in a point anteriorly; nostrils near the end of snout; eyes small and black; ear cavity in the form of a long tube, with its S-shaped opening on the back of the head. The spines are dirty white tipped with black, sharp, about 1¾ inches long, directed backward, and on the back inward, crossing each other on the mesial line. The hind feet in the natural position rest on their inner side, the concave surface looking outward, thus keeping the claws unworn for casting aside the earth loosened by the fore claws. In captivity it is a stupid creature, slow-moving, avoiding the light, and active only in burrowing, which it does with astonishing rapidity; specimens have been kept alive at the London zoological gardens, where they were fed on bread and milk; when irritated or asleep they roll themselves in a ball, the head between the fore legs. It can sink into loose sand directly downward, presenting only its spiny back to its enemies; in spite of its defensive armor it often falls a prey to the thylacine and other carnivorous marsupials. Its common name is inappropriate, as it is neither a rodent like the porcupine nor an edentate proper like the ant-eater, though it has the spiny covering of the one and the toothless jaws of the other; in some districts it is called the hedgehog, which is equally inapplicable, as the dentition of the insectivora is not represented in this animal; perhaps, however, the name here given, originally imposed by Shaw, is the best that could be selected. It is now rather rare in the colony. The *E. setosa* (Cuv.) has the fur so long as nearly to hide the shorter spines; the general color is brown, paler on the head and below; the length is from 14 to 17 inches; it is peculiar to Tasmania, and perhaps is only a variety of the other species, arising from living in a moister climate, which would tend to develop the hair and check the growth of the spines.

PORGY. See Scuppaug.

PORISM, a geometric proposition used by the ancient mathematicians, having for its ob-ot to find the conditions that will render rtain problems indeterminate or capable of numerable solutions. It is intermediate between the problem, in which something is prosed to be constructed, and the theorem, hich is something requiring demonstration. e recovery of this branch of the ancient analyis due to Prof. R. Simson, who deduced it om the imperfect mathematical work of Paps (1732). His restoration of Euclid's "Posms" was published after his death in 1776.

POROSITY (Gr. πόρος, a passage), the contion of open structure in which the particles matter are arranged in all bodies, leaving tween them pores or interstices that are supsed to be vacant or filled with air. The extence of such spaces even in the most solid dies is proved in various ways. When wood stone of the most compact structure is imersed in water under the receiver of an air mp and the air is exhausted from the surface, at contained in these bodies immediately akes its appearance rising from them in a ood of bubbles. Under great pressure water forced through the pores of cast iron, even 4 inches thickness. (See CANNON, and IRON, ol. ix. p. 590.) The porosity of this material evidently increased by dissolving out the rbon that is disseminated throughout its subance, by which it becomes malleable iron ithout change of form, but the change of xture thus indicated is not apparent to the ye. Density, which is the opposite condition porosity, is increased in most metals by presure and hammering. The molecules are thus rought into closer contact, and the body is und to possess greater specific gravity and trength. Liquids are also supposed to be orous from the fact that mixtures are someimes made which occupy less space than the um of the volumes of the ingredients when eparated. This is the case with alcohol and ater. Specific gravity, expressing the relaive weights or densities of bodies, also defines n inverse ratio their porosity.

PORPHYRY (Gr. πορφύρα, purple), a rock named from the prevalent color of the varieties used by the ancients, as the *rosso antico*, r red porphyry of Egypt. This variety consts of a ground or paste of reddish feldspar in hich are disseminated rose-colored crystals f the feldspar called oligoclase, with some lates of blackish hornblende and grains of perxide of iron. This in general is the character f porphyry; but the paste may be green, red, rple, or black, and the interspersed crystals ay present various shades, usually however ghter than the ground. They may be also of rnblende, quartz, augite, olivine, and other inerals. The rock is very hard and susceptible f a fine polish. Upon the smooth surface the ystals appear as blotches. Various rocks of n earthy or compact base with distinct interpersed crystals are termed porphyritic. Granite so called when it presents distinct feldspar ystals, and so is greenstone, trachyte, &c. The principal uses of porphyry are in architecture and ornamental articles, as vases, slabs, &c. No material is more durable, and none retains better the sharp lines and high polish which it receives. In modern times it is most successfully worked by the Swedes and Russians. Blocks for vases, after being chiselled nearly into shape, are turned in lathes, and worn down by the application of lumps of porphyry and emery and water. In the Swedish royal porphyry works of Dalecarlia vases, tazze, &c., of immense size are made, one of the latter exceeding 11 feet in diameter. A vase of pink granitoid porphyry 6 feet high and 4 feet 4 inches in diameter was sent to the great exhibition in London in 1851. Slabs of porphyry are employed in the arts with mullers of the same materials for grinding hard powdered substances to extreme fineness, and the process is thence termed porphyrization. In the United States porphyry is met with in granitic regions, and in general is found along the range of the veins of valuable metals in such regions.

PORPHYRY (Gr. Πορφύριος, *i. e.*, a wearer of purple), a philosopher of the Neo-Platonic school, born in Tyre, A. D. 233, died in Rome about 305. Some have supposed that he was of Jewish origin, but others that he falsely so asserted in order to obtain the more respect for his statements in relation to the Jewish Scriptures. He was a man of distinguished family, named Malchus, the Greek form of the Syro-Phœnician Moloch, signifying king; but he received from his preceptor Longinus, in allusion to the signification of this original title, the name by which he has ever since been known. He studied under Origen at Cæsarea, under Apollonius and Longinus at Athens, and at Rome under Plotinus, with whom he remained 6 years, at the end of which period he went to Sicily by the advice of his master, who had become aware that the pupil entertained the idea of suicide. While in Sicily he wrote his treatise against the Christian religion. He subsequently returned to Rome, and taught there for many years. The philosophical doctrines of Porphyry were essentially those of Plotinus. He insisted strongly on the contrast between the corporeal and the incorporeal, and the power of the latter over the former. The influence of the incorporeal was, in his view, unrestricted by the limits of space and independent of the accident of contiguity. When free from the intermixture of matter it is omnipresent and its power unlimited. The worship of the national gods of a people seems to have been upheld by him, on the ground that respect should be shown to the ancient religious usages of a nation; but he acknowledged one absolute supreme Deity, who is to be worshipped with pure words and thoughts. There are extant 19 different works of Porphyry, in whole or in part, mostly on the Neo-Platonic doctrines, and 21 are mentioned as lost. The most celebrated of the latter was his work "Against the Christians," which was publicly destroyed by order of the emperor

Theodosius. It was in 15 books, and treated both the Jewish and Christian Scriptures very minutely. In it he admits the wisdom of Christ, but asserts that the Christians had perverted what Christ originally taught.

PORPOISE, the common name of the small-sized cetacean mammals of the genus *phocæna* (Cuv.). The snout is short, uniformly rounded, wide from the breadth of the more horizontal intermaxillaries and maxillaries, without the prolonged beak, separated from the forehead by a distinct furrow, which characterizes the dolphin, to which family it also belongs. The name is evidently a corruption of the French *porc-poisson* (hog fish); it is called *Meerschwein* by the Germans, *marsouin* by the French, and sea hog and puffing pig by the English and Americans. Though an air-breathing mammal and not a fish, the shape of the body is fish-like and adapted for progression in the water; the jaws are armed with minute conical teeth; the blow-hole, on the top of the head, is transverse, crescentic, with the concavity forward. (For its anatomy see DOLPHIN.) There are several species in different parts of the world, some of which have a very wide geographical distribution; they are very active, living in shoals or flocks, and are frequently seen swimming and playing about vessels, running races with them, and leaping out of water in their sports; their food consists chiefly of fishes and cephalopod mollusks; their flesh is dark-colored and gorged with blood, and was once considered a delicacy, and is now often eaten by sailors; their blubber yields a very fine oil, and their skin makes an excellent leather. The common porpoise (*P. communis*, Cuv.) is from 4 to 6 feet long, bluish black above with violet or greenish reflections, and white beneath; a little behind the middle of the back is a triangular cutaneous fold or dorsal fin; teeth 20 to 24 on each side in both jaws, compressed laterally, and curved somewhat backward; the lower jaw the longer; the pupil is V-shaped reversed, and the tongue festooned all round; the skin is smooth, perfectly destitute of hair, and even of eyelashes, and beneath it is a layer of fat about an inch thick; there are no lips, and the small eyes are nearly in a line with the opening of the mouth; the opening of the ear is exceedingly small; neither the dorsal fin nor the tail has any internal bones, and the former consists of fat and is incapable of motion; the pectorals are brownish, though arising from a white part of the body; the brain is large, with numerous and deep convolutions over the cerebellum. There are 4 stomachs, and even 6 if all the constricted portions be counted as such; the walls of the 1st are strongly wrinkled, of the 2d very thick with longitudinal wrinkles of a pulpy consistence, the 3d membranous with numerous small pores, and the 4th wrinkled like the 1st; the intestine grows smaller to the anus, and the cæcum is absent. Gestation continues 6 months, and a single young one is produced at a birth, about 20 inches long, which is suckled and protected by the mother, as in other mammals; it can provide for itself at a year old. This species is common all about the coasts of Europe, extending even to the icy seas; they generally keep near the shores, where they root about with their snouts like hogs; they are often seen rolling and tumbling in the water, as they rise to the surface to breathe with a puffing sound; they look in the water like large black pigs, whence their common names. They pursue herrings, mackerel, salmon, and other fishes which swim in shoals, sometimes going far up rivers in the eagerness of their pursuit; they have been seen in the Thames at London, and in the Seine at Rouen and even at Paris. The common porpoise of the American coast, formerly considered the same as the *P. communis* of Europe, was described as distinct by Prof. Agassiz in 1850, under the name of *P. Americana*. In size and color the two species are very much alike; the general form of the skull is different, the posterior surface in the European species being nearly vertical, but much curved in the American; the teeth of the latter are divided on the broad faces near the summit by grooves almost into 3 lobes, those of the former being smooth; the dorsal fin in the American is serrated and furnished with very characteristic tubercles, which are not mentioned in the descriptions of the European; the temporal groove of the skull is as wide as long in *P. Americana*, but narrower and oblong in *P. communis*. This species is common on our coast, chiefly in spring and summer, appearing in pursuit of the herring and other migratory fish; it should not be confounded with the cetacean called the sea porpoise, a true dolphin, and only seen off soundings. It was in former years captured in great numbers near the E. end of Long island in large seines from which they were harpooned and dragged on shore; from the blubber of each animal about 6 gallons of oil are obtained. The Cape porpoise (*P. Capensis*, Duss.) is from 4 to 6 feet long, almost wholly black, with rather small pectorals; it is found about the Cape of Good Hope. The striped porpoise (*P. bivittata*, Less.), of the southern seas, has a short conical snout, and a moderately high, black dorsal fin in the middle of the body; the form is slender, the length being about 3 feet, and the thickness 10 inches; the upper half of the body is of a shining black color, the lower jaw and under parts white; the black of the sides has a white stripe from the snout to the tail, interrupted opposite the dorsal fin; the tail is brown, and the pectorals white with the anterior edge black. This is one of the handsomest of cetaceans.

PORPORA, NICOLO, an Italian composer, born in Naples in 1687, died there in 1767. He was instructed by Scarlatti, and first brought himself into notice at Vienna, where he gained the approbation of the emperor Charles VI. In 1726 he entered upon a career of great success at Venice, and thence proceeded to Dreson, successfully opposing the composer Hasse. In 1751 he returned to Naples and established a school of vocalism, in which were educated some of the most celebrated singers of the 18th century, including Farinelli, Caffarelli, and Gizziello. In 1733 he was engaged by a party opposed to Handel to direct a rival opera in London; but, although supported by Farinelli, he failed to make any impression, and returned to Italy so disheartened that for some years he refrained from composing. About 1750 he established himself in Vienna, where Haydn came under his influence; and subsequently he became principal master at the Incurabili conservatory in Venice. Late in life he retired to Naples, where he died in indigence. His works, comprising 50 operas and a great number of masses, cantatas, sonatas, &c., are distinguished by gravity and elevation of style. His character and some passages of his life are graphically sketched in George Sand's novel "Consuelo."

PORSENA, or **Porsenna**, **Lars**, a king of Clusium in Etruria, to whom, according to the legend, the Tarquins in the 2d year after their expulsion from Rome applied for assistance in recovering their kingdom. Porsena immediately marched with an Etruscan army to the fortified hill Janiculum, and on his appearance the Romans fled to the Tiber and to the Sublician bridge, apparently without striking a blow. The defence of the bridge was intrusted to Horatius Cocles, who held the Etruscans in check at one end while the bridge was broken down behind him, and then swam the river safely. Porsena now besieged the city, but having learned from C. Mucius Scævola after the siege had lasted for some time, that 300 noble Romans had bound themselves by an oath to kill him, he made peace upon the reception of hostages, and retired to Clusium. This legend is believed by critics to veil the fact of a short subjugation of Rome by the Etruscans, which is implied by Tacitus, Pliny, and other classical writers.

PORSON, **Richard**, an English scholar and critic, born in East Ruston, Norfolk, Dec. 25, 1759, died in London, Sept. 25, 1808. At the age of 9 he was sent to a village school at Happisburgh, where he remained 3 years. His father, who was parish clerk of East Ruston, required him to repeat every night all the lessons that he had gone through during the day; and to this early exercise of his memory may perhaps be attributed that retentive power for which it afterward became remarkable. He received some instruction gratuitously from the Rev. Charles Hewitt, and when 15 years of age was sent to Eton at the expense of some gentlemen of the neighborhood. He then knew by heart nearly the whole of Horace and Virgil, the Iliad, the Odyssey, and many parts of Cicero and Livy; and in his own opinion he acquired little at Eton but facility in Latin versification. In 1777, principally by the assistance of Sir George Baker, president of the royal college of physicians, he entered Trinity college, Cambridge, where he obtained a fellowship in 1781, and was graduated M.A. in 1785. In 1793 he was made regius professor of Greek in the university. The salary of this office was only £40 a year. Some conscientious scruples deterred him from subscribing to the 39 articles of the church of England, and as it was thus impossible for him to enter into holy orders he vacated his fellowship in accordance with the rules of the college, and it is said that he lived in London on a guinea a month. In 1792 a number of his friends subscribed the sum of £2,000, which was so invested as to give him for the rest of his life an income of £100 per annum; and on the establishment of the London institution, he was appointed head librarian, with a salary of £200. Sedentary and irregular habits had broken his constitution, and during the latter years of his life he was subject to a painful asthmatic disease, and was in general ill health. His first attempts as an author were made in Dr. Maty's "Review," as early as 1783, and consisted of articles on Æschylus, Brunck's Aristophanes, Weston's Hermesianax, and other subjects. In 1786 he added some notes to an edition of Xenophon's Anabasis, and in 1790 published notes on *Toupii Emendationes in Suidam*. He first appeared as an author in his own name in the letters to Archdeacon Travis upon the contested verse 1 John v. 7, entitled "Letters on the Three Witnesses" (1790). He contributed several critical articles to the "Monthly Review," added notes to the London edition of Heyne's Virgil, corrected the text of Æschylus for the Glasgow edition, prepared an edition of the *Hecuba*, *Orestes*, *Phœnissæ*, and *Medea* of Euripides; collated the Harleian manuscript of the Odyssey for the Grenville Homer, and added notes, and corrected the edition of Herodotus printed at Edinburgh in 1806. He bestowed considerable pains on the restoration of the Greek text of the Rosetta stone. His *Notæ in Aristophanem* and *Lectiones Platonicæ* were published in 1820. The work entitled *Adversaria* was arranged after Porson's death from memoranda found among his papers.—Porson is generally considered one of the greatest classical scholars of modern times, and without a rival as a sound, accurate, and refined Greek critic. He was singularly acute and cautious, and to the highest degree of patience and perseverance united excellent judgment. His memory was almost miraculous. He was familiar with the whole body of Greek literature, thoroughly versed in the standard works of French literature, and well read in the English classics. His recollection of the very words, in long passages of prose as well as verse, in English authors, was astonishing. The best founded complaint made against Porson is, that with his great capabilities he did so little. A very large sum was offered him for an edition of Aristophanes, but he would not undertake the work, though in the opinion of those qualified to judge it would not have occupied him more than 6 months. He has been described as an habitual drunkard, but apparently without truth, though he drank, and at times even to intoxication.—See "Life of Richard Porson, M.A.," by the Rev. John Selby Watson, M.A. (8vo., London, 1861).

PORT AU PRINCE, or PORT REPUBLICAIN, the capital of Hayti, situated on the W. coast, at the head of a bay of the same name; pop. estimated at 30,000. It is built on ground which rises gradually, and has a very attractive appearance from the sea; but on entering the streets it is found to be very filthy. The houses are generally of two stories, constructed slightly of wood, as best calculated to withstand the effects of earthquakes, which at different times have nearly destroyed the city, more particularly in 1751 and 1770. A few of the houses are built of stone or brick. The most important public edifices are the palace and the senate house. There is a Roman Catholic church, a lyceum, college, custom house, mint, and hospital. The ground in the vicinity is marshy, and the climate is unhealthy. The harbor is perfectly safe except between August and November, when hurricanes occur. A considerable trade is carried on, the principal exports being mahogany, logwood, honey, coffee, cocoa, and rags; and the imports manufactured goods, provisions, and lumber. During the year 1857–'8, 83 vessels under the U. S. flag entered the port with cargoes valued at $927,904, and sailed with return cargoes estimated at $10,961,836. The town has suffered severely from fire at different times, but more especially in the years 1784, 1820, 1822, and 1850.

PORT CARBON, a town of Schuylkill co., Penn., on the Schuylkill river at the mouth of Mill creek, 3 m. N. E. from Pottsville; pop. in 1860, 2,006. It is in the midst of a rich and extensive coal region, from which nearly its entire support is derived. It carries on an active trade in coal by means of the Schuylkill valley railroad and the Schuylkill navigation, of which it is the terminus. In 1829 there was but one house on the present site. Its progress was rapid for many years, but it seems to have reached its limits, not having increased in population for more than 10 years.

PORT ELIZABETH, a free port of Cape Colony, S. Africa, on the W. shore of Algoa bay; pop. in 1851, about 4,500. In 1855, 163 vessels, measuring 26,914 tons, entered the harbor; the total value of imports in the same year was £376,638, and of exports £584,447. A considerable trade is rising between Boston, Mass., and Port Elizabeth, *via* Cape Town; the chief imports being tobacco, provisions, flour, shoes, farming implements, and some cotton goods, beside an innumerable assortment of trifling manufactured articles. During the 9 months ending Sept. 30, 1857, the value of the imports from the United States amounted to $157,797, and the exports to the same, which consisted of raw produce, to $462,865.

PORT LOUIS, the capital of the island of Mauritius, situated near its N. W. extremity, at the head of a triangular bay; pop. about [illegible] It is well protected to seaward by forts, and by a strong citadel which commands all approaches. The town is open to the ocean on one side, and on the other sides enclosed by picturesque mountains. The fashionable resorts are Government street and the ground around the Champ de Mars; the latter is a beautiful semi-circular plain, used as a parade ground for the garrison, and a race course. Formerly the houses of Port Louis were entirely constructed of timber; but, in consequence of many destructive fires, a law has been in force for some years past to prevent the erection of wooden dwellings. The government house, barracks, and many other large buildings, erected by the French, are still in excellent preservation. A dry dock was opened in 1859, capable of taking in a vessel [illegible] feet long; it is 80 feet wide at the top and [illegible] at bottom, and has 23 feet water on the sill at high tide. Two lighthouses have been completed, the main light on Flat island, with a subsidiary one on Cannonier point. There are several churches and schools, a theatre, and the usual government and public buildings.

PORT MAHON, the capital of the island of Minorca, situated 2 m. from the mouth of a bay a league in extent, in lat 39° 52′ N. and long. 4° 20′ E.; pop. 13,280. The city is of modern construction, and contains some fine public buildings and several schools and charitable institutions. Many of the houses are built on ledges of rock projecting over the sea. They are usually of stone, and have a neat and attractive appearance. The bay forms the finest harbor in the Mediterranean. It extends about 5 m. inland, having a narrow entrance between ledges of rock. It is defended by batteries mounting heavy guns. Manufactures and trade are decaying.

PORT ROYAL, a convent of Cistercian nuns near Versailles, which gained a world-wide celebrity in the history of the Jansenist controversy. The influence of the Jansenist doctrines on the nuns commenced when the first leader of the French Jansenists, the gifted abbé de St. Cyran, became their confessor. The abbess, Angélique Arnauld, in particular, became an enthusiastic admirer of the system. With her, the entire influential family of the Arnaulds, whose hereditary opposition to the Jesuits was said to be their second "original sin," was gained. Angélique was a daughter of Antoine Arnauld, an eminent advocate, and after his death (1626) his wife and several of his daughters entered Port Royal, and soon 5 daughters of his eldest son Robert followed their example. Some of the male members of the family organized a religious community in the neighborhood of the nuns; among them were Antoine Lemaître, a grandson of Antoine Arnauld, and one of the most illustrious orators of his time, who renounced a brilliant ca-year in order to do penance under the guidance of St. Cyran; Simon Séricourt (1638), Isaac de Sacy, Robert Arnauld (after the death of his wife), and the youngest brother of the latter, Dr. Antoine Arnauld, who by his impetuous eloquence and his astonishing learning subsequently became the head of the French Jansenists. All these occupied Port Royal, when the nuns in 1638 removed to a convent in Paris, and they were soon joined by Singlin, who after the death of St. Cyran became the confessor of the nuns, the physician Hamon, the dukes of Luynes and Liancourt, and others. Pascal, Nicole, and Lancelot maintained intimate relations with them; Boileau was their friend, and Racine, who wrote a history of Port Royal, was their pupil. The mode of life in Port Royal was distinguished for austerity. They rose at 3 o'clock in the morning; after the common morning prayer they kissed the ground, as a sign of their self-humiliation before God. Then they read, kneeling, a chapter from the Gospels, and one from the Epistles, and concluded with another prayer. Two hours in the morning and two in the afternoon were devoted to manual labor in the gardens adjoining the convent, and they observed with great strictness the season of Lent. The teaching of Port Royal obtained a wide celebrity under the guidance of Lancelot, and its boarding schools were resorted to by pupils from all parts of France. Their fame was in all mouths, but Cardinal Richelieu subjected them to a judicial investigation in 1638 and imprisoned the abbé de St. Cyran. After the death of Richelieu (1642), St. Cyran regained his liberty, but soon died, prophesying that for the contest against the Jesuits, the chief opponents of Jansenism, he would leave 20 disciples stronger than himself. In the same year Dr. Antoine Arnauld, by his treatise *De la fréquente communion*, charging the Jesuits with admitting people of the world without due preparation to the Lord's supper, opened the war between Port Royal and the Jesuits, which was only to end with the suppression of the former. The contest soon assumed a political character, the Jesuits having the government on their side, and generally also the Sorbonne, while Port Royal was supported by the parliament, and by a few illustrious personages, among whom was the duchess of Longueville, who established herself in the vicinity of the convent. The recluses of Port Royal remained the leaders and the centre of the opposition to the papal efforts for the suppression of Jansenism, and the nuns consistently refused to subscribe to the condemnatory decrees, except once, in 1665, when the advocates of Jansenism had secured a kind of compromise. Singularly enough, it was the bold defence of the rights of the popes on the part of two Jansenist bishops against the despotic caprices of Louis XIV., which led to the scattering of the community, the heads of whom, Arnauld and Nicole, had to flee from France. The nuns, some of whom had previously returned from Paris to Port Royal, were forbidden to receive novices, but kept up their resistance to the decrees against Jansenism until 1709, when a royal ordinance decreed the suppression of both their convents, that of Paris and the original Port Royal (Port Royal des Champs), and the distribution of the nuns among different convents of other dioceses. As its history was so closely interwoven with that of Jansenism, the monastic community of Port Royal has never been revived.—Several distinguished historians have written the history of this most celebrated of all monastic establishments; among them the best and most recent are: Reuchlin, *Geschichte von Port Royal* (2 vols., Hamburg, 1839–'44); Ste. Beuve (the descendant of a Jansenist family), *Port Royal* (2 vols., Paris, 1840–'42); Beard, "Port Royal, a Contribution to the History of Religion and Literature in France" (2 vols. 8vo., London, 1861).

PORT WINE, a Portuguese wine produced in the vicinity of Oporto on the Douro. The principal vineyards are in the mountainous districts called the Alto-Douro, about 15 leagues from the city, where the vines are cultivated in terraces, and not suffered to grow higher than 8½ feet. The vintage begins in September and lasts about a month. The juice, having been pressed from the grapes by the treading process, is placed in casks to ferment, and then transferred to large vats where a second fermentation ensues. In the winter it is racked into pipes and conveyed to Oporto. The wines produced are of various qualities, but those intended for exportation are submitted to inspectors, who permit none but a strong, dark, sweet kind to leave the country. Hence, it is said, the best wines are kept at home, and the exported wines are generally adulterated to a large extent to give them the prescribed strength and color. Brandy is added to them when they are deposited in the stores, and again when they are shipped, which is in most cases about a year after the vintage. When white grapes have been largely used instead of black, elder berries or some other coloring substances are added. The exported wine should remain several years in the wood in order to abate its sweet and astringent flavor, but the aroma of the grape does not entirely overcome the taste and odor of brandy until it has been 10 or 15 years in bottle. The average yield of the Alto-Douro district, until the vine disease made its appearance about 1854, was not far from 105,000 pipes, or rather more than one pipe per acre, one half of which was declared fit for exportation. In 1856–'7 the wine shipped from the Douro amounted to 35,264 pipes, in 1857–'8 to 19,212, and in 1858–'9 to 17,597. Much the larger part of this is sent to England.

PORTA, Baccio della. See Baccio.

PORTA, Giambattista, an Italian natural philosopher, born in Naples about 1550, died there, Feb. 4, 1615. In his zeal for the advancement of science he opened his house to a society of literary men called *i secreti*, whose meetings were finally prohibited by the court of Rome, on the supposition that magic and other unlawful secrets were discussed at them. He travelled extensively over Europe, liberally aiding the establishment of private schools for the study of particular sciences and of public academies. Late in life he wrote dramas which are now forgotten. His investigations, though in themselves incomplete and frequently absurd, have proved of great value to subsequent philosophers. The theory of light is much indebted to his labors, and he was the inventor of the camera obscura and other optical instruments, including, it was formerly supposed, the telescope. He was a voluminous writer on a great variety of subjects, including natural magic, the art of secret writing, human physiognomy, landscape gardening, optics, curvilinear geometry, chemistry, meteorology, &c. His chief work, *De Humana Physiognomia* (fol., Naples, 1598), entitles him to be considered the true founder of physiognomy.

PORTAGE. I. A N. E. co. of Ohio, drained by Cuyahoga and Mahoning rivers; area, 500 sq. m.; pop. in 1860, 24,206. It has a nearly level surface and a fertile soil. The productions in 1850 were 264,171 bushels of Indian corn, 187,147 of wheat, 162,828 of oats, 46,189 tons of hay, 295,069 lbs. of wool, and 662,614 of butter. There were 12 grist mills, 18 saw mills, 3 iron founderies, 5 woollen factories, 12 tanneries, 4 newspaper offices, 60 churches, and 11,024 pupils attending public schools. It is intersected by the Pennsylvania and Ohio canal, and by the Cleveland and Mahoning and Cleveland and Pittsburg railroads, the latter of which passes through the capital, Ravenna. II. A central co. of Wis., intersected by Wisconsin river and drained by several of its branches; area, 1,650 sq. m.; pop. in 1860, 7,509. It contains extensive pine forests, from which large quantities of lumber are rafted down the river. Capital, Plover.

PORTAGE CITY, a village and the capital of Columbia co., Wis., on the Wisconsin river, about 100 m. from its source, and on the La Crosse and Milwaukee railroad, 95 m. N. W. from Milwaukee and 105 m. E. S. E. from La Crosse; pop. in 1860, 2,950. At this point the Wisconsin river is connected with the Fox by means of the Fox and Wisconsin river improvement, which here furnishes abundant water power, as well as an outlet eastward through Green bay for the produce of the interior, and southward by the Mississippi for large quantities of manufactured lumber from N. E. Wisconsin. Railways will soon be completed from Portage to Madison, 36 m. S., and Columbus, 27 m. S. E. The principal manufactures are lumber, flour, brick, and pottery, and there are two large breweries, a foundery, and several smaller manufactories. There are 5 churches, Baptist, Episcopalian, Methodist, Presbyterian, and Roman Catholic.

PORTALIS, JEAN ÉTIENNE MARIE, a French lawyer and statesman, born in Beausset, Provence, in 1746, died in 1807. He was admitted as an advocate by the parliament of Aix at the age of 21. His memorial "On the Validity of Protestant Marriages in France" (1770) first made him known beyond his department, and his conduct of cases against Mirabeau and Beaumarchais gave him an extended reputation. Upon the breaking out of the revolution he fled to Lyons, but in 1793 went to Paris, where he was arrested and imprisoned, and only obtained his liberty upon the fall of Robespierre. In 1795 he was a member of the council of the ancients, and opposed the directory. He was proscribed on the 18th Fructidor (1797) and took refuge in Germany, whence he returned in 1800. In 1801 he was made a councillor of state, and assisted in the preparation of the civil code; and in the same year he became minister of public worship, and in 1803 a senator. He was the author of a *Traité sur l'usage et l'abus de l'esprit philosophique, pendant le XVIIIe siècle.*—JOSEPH MARIE, count, a French statesman, son of the preceding, born in Aix, Bouches-du-Rhône, Feb. 19, 1778. Having obtained a diplomatic appointment, he took part in the negotiations which ended in the peace of Amiens, and was for some time minister plenipotentiary at Ratisbon. When his father became minister of public worship he was made secretary-general of that department. In 1810 he was made councillor of state and censor of the press. When the trouble occurred between Napoleon I. and the pope, the relations of Portalis with the abbé d'Astros excited the emperor's displeasure, and he was banished from Paris. Two years later he was made president of the imperial court at Angers. Upon the first restoration he was confirmed in the position and made councillor of state, and during the Hundred Days he again attached himself to the emperor. After the battle of Waterloo he once more obtained the royal favor, and in 1816 was made a councillor of the court of cassation; in 1818 ambassador to Rome; in 1819 peer of France; in 1824 president of a chamber of the court of cassation; and subsequently minister of foreign affairs, and first president of the court of cassation. After the *coup d'état* of 1851 he was one of the commission of consultation, and in 1852 was made a senator. He is the author of a work on French literature and philosophy, prefixed to his edition of his father's work above mentioned.

PORTER, a kind of malt liquor. See BREWING.

PORTER, a N. W. co. of Ind., bordered N. by Lake Michigan and S. by the Kankakee river, and drained by Calumet river and Coffee and Salt creeks; area, about 420 sq. m.; pop. in 1850, 5,234; in 1860, 10,302. It has a nearly level surface toward the N., which becomes rough and broken in the S.; and the soil, now principally occupied by forest and prairie, is generally fertile. The productions in 1850 were 205,655 bushels of Indian corn, 70,252 of wheat, 76,143 of oats, 5,806 tons of hay, and 90,942 lbs. of wool. There were 5 grist mills, 41 churches, and 1,418 pupils attending public schools. It is intersected by the Michigan southern and northern Indiana, the Michigan central, and the Pittsburg, Fort Wayne, and Chicago railroads, the last passing through the capital, Valparaiso.

PORTER, Alexander, an American jurist, born near Omagh, county Tyrone, Ireland, in 1786, died in St. Mary's parish, La., Jan. 13, 1844. In 1801 he emigrated to the United States, and settled in Nashville, Tenn., where in 1807 he was admitted to the bar. In 1810 he removed to St. Martinsville, La., and in 1811 was elected a member of the convention which framed the first constitution of Louisiana. Before reaching the age of 30 he was one of the leading lawyers of the state, and at the same time was an extensive and successful sugar planter. In 1821 he was appointed a judge of the supreme court of Louisiana, a position which he filled for 12 years. Great confusion existed in the state in consequence of the attempt to engraft certain principles of the common law upon the mixed system of Spanish, French, and civil law which then prevailed; and to the labors of Judge Porter and his associates on the bench, Judges Matthews and Martin, is due the system of jurisprudence at present existing in Louisiana. In Dec. 1833, he resigned office, and in the same month was elected a senator in congress. In politics he was a whig, and one of his first legislative votes was recorded in favor of Mr. Clay's resolutions censuring President Jackson for removing the deposits. Subsequently he spoke in favor of the bill prohibiting the circulation in the southern states, through the mail, of publications that might excite insurrections among the slaves, and of Mr. Calhoun's motion to reject petitions for the abolition of slavery in the district of Columbia. In March, 1836, he made his most elaborate parliamentary effort in reply to a speech of Mr. Benton upon the introduction of his "expunging resolutions." He also opposed Benton's bill for compelling payments for public lands to be made in specie, and favored the division among the states of the surplus revenue remaining in the treasury at the end of each year, and the recognition of the independence of Texas. In the latter part of 1836 he resigned. In Jan. 1843, he was reelected a senator for 6 years from the ensuing March, but was prevented by ill health from taking his seat.

PORTER, Benjamin F., an American jurist, born in Charleston, S. C., in Sept. 1808. His circumstances were humble, and his education was acquired by private study. He was admitted to the bar in Charleston at an early age, afterward studied medicine, and, removing to Alabama in 1830, practised the latter profession for a short time, when he returned to the law. He was elected a member of the legislature in 1832, and in 1835 reporter of the state. In 1840 he was elevated to the bench, but resigned office soon after in consequence of some scruples as to the constitutionality of his election. He has edited 14 volumes of the Alabama reports, and translated the "Elements of the Institutes" of Heineccius. He has also contributed largely to periodicals, has been frequently an orator on public occasions, and has published among other works a collection of poems, chiefly lyrical, in Charleston.

PORTER, David, an officer of the U. S. navy, born in Boston, Mass., in Feb. 1780, died in Pera, March 28, 1843. He entered the navy in April, 1798, as a midshipman in the frigate Constellation, and was in that ship in her action with the French frigate Insurgente, Feb. 9, 1799. In Oct. 1799, he became a lieutenant, and served on the West India station in the schooner Experiment, 12. In Jan. 1800, the Experiment, while becalmed in the bight of Leogane, coast of St. Domingo, with several American merchantmen under her protection, was attacked by 10 barges well manned and armed. After a conflict of 7 hours, during which the barges went twice to the shore to land their killed and wounded, and receive reënforcements, they were beaten off. Lieut. Porter was wounded in this engagement. Subsequently the Experiment had several spirited and successful affairs with privateers, and captured the French man-of-war schooner La Diana, 14 guns and 60 men. In 1801 Porter was attached as first lieutenant to the schooner Enterprise, 12, in the Mediterranean. In Aug. 1801, the Enterprise fell in, off Malta, with a Tripolitan cruiser of 14 guns and 80 men, which, after an engagement of 3 hours, surrendered, and was taken possession of by Lieut. Porter. Subsequently, while attached to the frigate New York, he commanded a boat expedition sent to destroy several vessels in the harbor of Old Tripoli, which service was effectually performed, he receiving a severe wound. In Sept. 1803, he was attached to the frigate Philadelphia, in which ship he was captured in October of that year (see Bainbridge, William), and remained a prisoner in Tripoli until peace was proclaimed. In April, 1806, he was promoted to the rank of master commandant, and in July, 1812, to that of captain. A few days after the declaration of the war of 1812 against England, he sailed from New York in command of the frigate Essex, 32, and in a very short cruise captured a number of British merchantmen. He also with great address succeeded in capturing one of a fleet of transports convoyed by a frigate and bomb vessel. This prize had 150 troops on board. Soon afterward he fell in with and captured, after an action of 8 minutes, H. B. M. S. Alert, of 20 18-lb. carronades, with a full crew. So well directed was the American fire, that the Alert surrendered with 7 feet water in her hold, while the Essex was uninjured. Soon after the capture of the Alert, the Essex came into the Delaware for water and provisions, and sailed again on Oct. 27, 1812, she now being one of a squadron of 3 vessels under the command of Commodore William Bainbridge. On Dec. 11 she captured near the equator the British government packet Nocton, with $50,000 in specie on board. Capt. Porter continued to cruise in the south Atlantic, and upon the coast of Brazil, until the close of Jan. 1813, when, having failed to fall in with Commodore Bainbridge at 3 different rendezvous which had been appointed, and having ascertained that he had in fact returned to the United States, he determined to proceed to the Pacific, and destroy the English whale fishery in that ocean. The possession of the specie taken from the Nocton, and the knowledge that the whalers were always well provided with provisions, satisfied him that he could live upon the enemy, and that his plan was therefore practicable. The Essex left St. Catharine's on Jan. 26, and after a tempestuous passage round Cape Horn was fairly in the Pacific on March 5, 1813. On the 15th he anchored for supplies in the port of Valparaiso, where his reception was favorable, Chili having declared her independence of Spain. While in this port he obtained much valuable intelligence in regard to the British and American trade in the Pacific, and also learned that Peru had sent out cruisers against American commerce, under the impression that Spain would soon declare war against the United States, which might legalize their captures. The supplies of the Essex being completed, she went to sea, and on March 25 captured the Peruvian privateer Nereyda, of 19 guns, which had taken two American whale ships, and had their crews on board as prisoners. They were transferred to the Essex, and the armament, ammunition, shot, small arms, &c., of the Nereyda were thrown overboard, when she was released. One of her prizes was shortly afterward recaptured and restored to her commander. After this, Capt. Porter cruised about 10 months in the Pacific, refitting his ship in the bay of Nukahiva. In this cruise most important service was performed by the Essex. American ships, nearly all of which would otherwise have been captured, were protected; 12 British ships employed chiefly in the sperm whale fishery, amounting in the aggregate to 3,369 tons, were captured; 400 prisoners were made; and for the time that important British interest in the Pacific was destroyed. The Georgiana, whaler, was converted into a vessel of war, named the Essex Junior, and cruised in company with the Essex, under the command of Lieut. John Downes. The expectation which Capt. Porter had formed of living upon the enemy was fully realized, all the provisions, clothing, medicines, and stores of every description necessary for the Essex being taken from her prizes. On Dec. 12, 1813, the Essex and Essex Junior sailed from the bay of Nukahiva, and on Feb. 3, 1814, they arrived at Valparaiso. On the 8th H. B. M. frigate Phœbe, rated 36, Capt. James Hillyar, and sloop Cherub, rated 20, Capt. Tucker, arrived, and anchored near the Essex. The Phœbe, on entering the port, approached the Essex nearer than strict neutrality seemed to justify, and being taken aback at an unfortunate moment, her jib-boom came across the forecastle of the latter. All hands were called "to board the enemy!" and in an instant the entire crew of the Essex were ready to spring completely armed upon the decks of the Phœbe. But as the hulls of the ships did not absolutely touch, and Capt. Hillyar apologized for the accident, Capt. Porter declined to profit by the manifest advantage he had over the Phœbe, and no conflict took place. Capt. Porter was visited on shore by the two British captains the day after their arrival, and Capt. Hillyar distinctly avowed his intention to respect the neutrality of the port. The English ships, having obtained their supplies, cruised off Valparaiso 6 weeks. The Essex made several unsuccessful attempts to engage the Phœbe alone, but there is little doubt that Capt. Hillyar was instructed not to permit this if it could possibly be avoided. The numerous captures made by the Essex had filled the English underwriters and merchants who had property in the Pacific with such apprehension, that her capture at all hazards was resolved upon; and not only were these two ships despatched in quest of her, but others were sent for the same object to the China seas, off New Zealand, Timor, and New Holland, and a frigate to the river La Plata. On March 28 the Essex made an attempt to get to sea, but in doubling a headland was struck by a squall, which carried away her maintopmast, causing the loss of several men. In this crippled state the ship was anchored 3 miles from the town, and within pistol shot from the shore. She was, moreover, within half a mile of a small battery. In this situation she was attacked by the Phœbe and Cherub. The exact force of the combatants was as follows. The Essex was a frigate of 860 tons, mounting 32 guns, 6 of which were long 12s, the rest 32-lb. carronades, and mustered, when she went into action, 255 souls. The Phœbe was a frigate of 926 tons, mounting 46 guns, viz., 30 long 18s and 16 32-lb. carronades, and mustered 320 souls. The Cherub mounted 28 guns, viz., 18 32-lb. carronades, 8 24-lb carronades, and 2 long 9s, with a crew of 180 souls. At 4 P. M. the Phœbe, having obtained a good position, nearly astern of the Essex, opened her fire at long shot, the Cherub opening hers at the same time on the starboard bow. The action thus commenced continued 2 hours and 30 minutes, and was undoubtedly one of the most remarkable in the history of naval warfare. The Essex Junior took no part in it, her armament of 18-lb. carronades being too light to be of the least service in such an action. The Essex finally surrendered, with a loss of 58 killed, 66 wounded, and 31 missing—making a total loss of 152 out of 255. Of the missing, most were probably drowned in attempting to swim ashore when the ship was on fire, which was the case at one time during the engagement; and when she surrendered, Capt. Porter and Lieut. McKnight were the only commissioned sea officers who remained unhurt. A large portion of her guns were disabled, the berth deck, ward room, steerage, and cockpit were full of wounded, and some of the latter were killed even while under the surgeon's hands. The sea was perfectly smooth, and the Cherub fired her long 18s during the latter part of the engagement at a nearly unresisting ship. The British loss was but slight, 5 killed and 10 wounded, the first lieutenant of the Phœbe among the former. Capt. Tucker of the Cherub was wounded. Capt. Porter now made arrangements with Capt. Hillyar for the conversion of the Essex Junior into a cartel, and all the survivors of the Essex came to the United States in her. On his arrival he was received with great distinction. His narrative of this remarkable cruise was published in New York in 1822 (2 vols. 8vo.). From April, 1815, to Dec. 1823, he served as a member of the board of navy commissioners, which position he resigned to take command of an expedition fitted out against pirates in the West Indies. The squadron consisted of 3 sloops of war, 12 smaller vessels, and 5 barges. A depot was established at Thompson's island near Key West, and a system of the most active, arduous cruising at once commenced. In Oct. 1824, upon evidence that a quantity of valuable goods had been carried by pirates to a small town on the E. end of Porto Rico called Faxardo, the Beagle, one of the schooners of the squadron, was sent to aid in recovering it. Her commander, with one of his officers, visited the town and waited upon the proper authorities; but their commissions, which were duly produced, were pronounced forgeries, and these officers, charged with being pirates, were thrown into prison. After various other insults they were permitted to return to their vessel. Com. Porter deemed this an insult to the flag of the United States which must be atoned for; and as soon as the necessary arrangements could be made, he landed a force of 200 men, and demanded reparation. This was given. The authorities apologized to the commander of the Beagle personally, and promised thereafter to respect the rights of the American officers. For this step Com. Porter was recalled from his command. The government deemed that he had exceeded his powers, and a court martial sentenced him to a suspension for 6 months. He soon afterward resigned, and entered the service of Mexico as commander-in-chief of her naval forces, at a salary of $25,000 per annum. He remained in this service until 1829, when he returned to the United States, and was appointed by President Jackson consul-general to the Barbary powers, from which post he was transferred to Constantinople as chargé d'affaires, and finally became resident minister there, which office he held when he died. His remains were interred in the grounds of the naval asylum at Philadelphia.

PORTER, Ebenezer, an American divine, born in Cornwall, Conn., Oct. 5, 1772, died in Andover, Mass., April 8, 1834. He was graduated at Dartmouth college in 1792, studied divinity in a private theological seminary at Bethlehem, Conn., and was ordained pastor of the Congregational church at Washington in that state in 1796. In 1812 he was appointed professor of sacred rhetoric at Andover theological seminary, of which institution he subsequently became president. He wrote "The Young Preacher's Manual" (1819); "Analysis of Vocal Inflection" (1824); "Analysis of the Principles of Rhetorical Delivery" (1827); and "Lectures on Homiletics and Preaching, and on Public Prayer, with Sermons and Addresses" (1834). A collection of his "Lectures on Eloquence and Style" was published by the Rev. L. Matthews (8vo., Andover, 1836).

PORTER, Jane, an English novelist, born in Durham in 1776, died in Bristol, May 24, 1850. She lost her father in childhood, was educated at Edinburgh, and afterward removed to London with her mother and sister. Here she published her first novel, "Thaddeus of Warsaw," which was translated into several continental languages, and obtained for her the compliment of admission as a lady canoness into the Teutonic order of St. Joachim. In 1809 she published "The Scottish Chiefs," a novel founded on the adventures of Bruce and Wallace, which like the preceding was very popular, giving a highly romantic account of the character and times of its heroes. "The Pastor's Fireside," "Duke Christian of Luneburgh," "The Field of Forty Footsteps," and "Sir Edward Seaward's Diary" (1831) are her other most important works. The last is a work of fiction, but so life-like in its style and narrative that a leading review discussed it as a veritable history. In 1841 Miss Porter accompanied her brother, Sir Robert Ker Porter, to St. Petersburg, and after his death returned to England.—Anna Maria, sister of the preceding, born in Durham about 1781, died near Bristol, June 21, 1832. In her childhood she was much in the company of Walter Scott, who delighted in relating stories to her. Her first works were two collections of "Artless Tales" (1793 and 1795), beside which she wrote "Walsh Colville" (1797), "Octavia" (3 vols., 1798), "The Hungarian Brothers" (1807), "Don Sebastian" (1809), "Ballad Romances and other Poems" (1811), "The Recluse of Norway" (1814), "The Village of Mariendorpt," "The Fast of St. Magdalen," "The Knight of St. John," in conjunction with her sister Jane, and "Tales round a Winter's Hearth."

PORTER, Peter Buell, an American soldier, born in Salisbury, Conn., Aug. 14, 1773, died at Niagara Falls, March 20, 1844. He was graduated at Yale college in 1791, studied at the Litchfield law school, and in 1795 began practice at Canandaigua, N. Y. In 1809 he was chosen a representative in congress, where as chairman of the committee on foreign relations he prepared and introduced the celebrated report of Dec. 1811, recommending war against Great Britain. As soon as hostilities had been declared he resigned his seat in congress, and, refusing a commission as general in the regular army, was appointed quartermaster-general of New York, and after some time spent in arousing the military spirit of the state, received the command of a body of Pennsylvania and New York volunteers and Indians of the Six Nations. Black Rock, where Gen. Porter resided, having fallen into the hands of the British in June, 1813, and his own house, from which he had barely time to escape, made their headquarters, he rallied a force by which they were expelled, and their commander, Col. Bishop, mortally wounded. He held a command in Smythe's unfortunate "army of invasion," and was twice permitted to embark to lead the van of the army into Canada, and twice recalled before he reached the opposite shore. His comments on this treatment led to a duel between him and Gen. Smythe. In July, 1814, he joined Brown's invading army with a brigade of 3,500 volunteers and Indians. He exhibited "great personal gallantry" at Chippewa, and led the volunteers at Lundy's Lane. Besieged with Brown in Fort Erie, he led the brilliant and effective sortie of Sept. 17. Passing during the engagement with his staff from one column to another, he came suddenly upon a party of some 80 English soldiers, separated from the main body, and bewildered in the *mêlée*. He went up to them, putting on a bold face, and saying: "That's right, my good fellows! surrender, and I'll take care of you," at the same time throwing down the muskets of those nearest to him. This had been done to a number, when the remainder, recovering their presence of mind, rushed upon him and would have made him prisoner, had not a body of Americans providentially appeared to rescue the general, and kill or capture the enemy. A gold medal from congress, and a sword from the state, testified the public appreciation of his services. Gen. Porter was identified with the progress of western New York, was one of the earliest projectors of the Erie canal, and was named, with Morris and Clinton, on the first board of commissioners to explore a route for it. In 1816 he was appointed commissioner under the treaty of Ghent for determining the N. W. boundary. In May, 1828, he was appointed secretary of war by President Adams.

PORTER, Sir Robert Ker, an English artist and traveller, brother of Jane and Anna Maria Porter, born in Durham in 1780, died in St. Petersburg in May, 1842. His taste for art was awakened by Flora Macdonald while he was pursuing his education at Edinburgh. Through the influence of West he was admitted to the royal academy at the age of 10, and at the age of 12 was commissioned to paint "Moses and Aaron" for Shoreditch church. His most remarkable productions were battle pieces. His "Storming of Seringapatam," which was exhibited in 1800, was 120 feet long, and is said to have cost him only 6 weeks' labor. It was destroyed by fire. He also painted "The Siege of Acre," "Agincourt," "The Battle of Alexandria," and "The Death of Sir Ralph Abercromby." In 1804 he went to Russia where he obtained the appointment of historical painter to the czar, and painted on the walls of the admiralty "Peter the Great planning the Port of Cronstadt and St. Petersburg." Returning to England about 1806, he published "Travelling Sketches in Russia and Sweden" (2 vols. 4to., 1808); accompanied Sir John Moore's expedition to the Peninsula in 1808–'9; wrote anonymous "Letters from Portugal and Spain" (1809); and afterward made a second visit to Russia, where in 1811 he married the daughter of Prince Sherbatoff. In 1813 he published "An Account of the Russian Campaign." From 1817 to 1820 he travelled in Asia, engaged in antiquarian studies, which are detailed in his "Travels in Georgia, Persia, Armenia, ancient Babylonia," &c. (2 vols. 4to., 1821–'2). In 1826 he was appointed British consul at Caracas, Venezuela, where he painted three of his best pictures, "Christ at the Last Supper blessing the Cup," "Our Saviour blessing the Little Child," and an *Ecce Homo*. Having obtained leave of absence for the purpose of another visit to Russia, he went with his sister Jane to St. Petersburg, and died of apoplexy as he was about returning home. He was knighted by the prince regent in 1813.

PORTEUS, Beilby, an English prelate, born in York in 1731, died in London, May 14, 1809. He was admitted a sizar of Christ's college, Cambridge, where he obtained a fellowship. He first became known as a writer by his prize poem on death. In 1762 he became chaplain to Dr. Secker, archbishop of Canterbury, by whom he was presented to several benefices, and in 1769 chaplain to George III. and master of the hospital of St. Cross, near Winchester. In 1776 he was made bishop of Chester, and in 1787 was promoted to the diocese of London, over which he presided till his death. He established a fund for the relief of the poorer clergy of his diocese, and founded 3 prizes in Christ's college, Cambridge, as incitements to the study of divinity. His collected works, including sermons, tracts, a "Summary of Christian Evidences," a "Life of Archbishop Secker," &c., with a life by his nephew the Rev. Robert Hodgson, were published in 1816 (6 vols. 8vo., London).

PORTICO (Ital.; Lat. *porticus*), in architecture, a term originally applied to any sheltered place for walking supported by columns or arches, but now restricted in its signification to a sheltered space enclosed by columns at the entrance of a building. Such structures are usually roofed with a pediment, and in appearance resemble the front or end of a Greek temple. They have an even number of columns, ranging from 4 to 12, in front, and are called prostyle when they project from the main building. Such as are recessed within the front of a building, or, technically speaking, *in antis*, are properly *loggie*. The portico differs from the porch, with which it is frequently confounded, in forming an integral part, or perhaps the whole, of the front of a building, while the porch is only a subordinate part of the building to which it is attached. The most celebrated and perfect specimen of the portico is that of the Parthenon in Athens. (See ARCADE, and COLONNADE.)

PORTINARI. See BEATRICE.

PORTLAND, a city and port of entry, capital of Cumberland co., Me., situated on an arm of the S. W. side of Casco bay, in lat. 43° 39' N., long. 70° 15' W., 105 m. by railroad N. N. E. from Boston; pop. in 1860, 26,342. It stands upon a peninsula, about 3 m. long, with an average breadth of ¾ m., extending into the bay in an easterly direction, with the surface rising from the sides and forming an elevated ridge which terminates at its extremities in two considerable hills. The harbor has sufficient depth of water for vessels of the largest class, is very extensive and well sheltered by several islands, and in the most severe winters is seldom closed by ice. It is of easy access, and the principal entrance, which lies between the mainland and House island, is defended by Fort Preble on the former and Fort Scammel on the latter. The U. S. government is now erecting a new granite casemated fort on Hog Island ledge in the harbor, which will command the 4 entrances. The greater part of the city is regularly laid out and well built, principally of brick, and is remarkable for the elegance of many of the houses. Many of the streets are lined with elm and other shade trees. The new custom house, post office, and United States court rooms occupy a handsome structure at the corner of Exchange and Middle streets, 125 feet in length, 65 feet in breadth, and 3 stories high. It is built of granite and iron, perfectly fire-proof. Portland has 26 churches, several of which are built of stone and brick, and in size and style compare favorably with the best in New England. The new city hall is one of the largest and most elegant public buildings in the country. Its front of olive-colored freestone, elaborately dressed, is 150 feet long, over 60 feet high, and surmounted with an elegant dome; its side elevation on Myrtle street is 232 feet, embracing a hall which is 112 by 82 feet, and capable of seating 2,500 persons. It cost about $275,000, and covers an area of over 25,000 feet. The Maine charitable mechanic association, incorporated in 1815, has erected a substantial granite and brick building on Congress street. It contains a fine hall, library, and other rooms, and cost $26,000. Its library, intended for the use of members and apprentices, numbers about 2,000 volumes. The Portland Athenæum was incorporated as a public library in 1827; it has over 9,000 volumes, and has lately erected a substantial brick library room on Plumb street, 60 by 36 feet. The society of natural history, organized in 1843, has a cabinet containing specimens of the ornithology of the state, a valuable collection of shells, numerous mineralogical and geological specimens, and a cabinet of different kinds of animals. It possesses a commodious brick hall and lecture room on Congress street. The mercantile library association, organized in 1851, sustains a course of public lectures annually, and has a library of over 3,000 volumes. Great attention is paid to education in the public schools, of which there are 26 in the city and its environs. Of these, one is a classical school for boys, one a high school for girls, and 2 intermediate for boys and girls; 6 are grammar schools, 3 for girls and 3 for boys; and the remainder are primary schools. The annual expenditure for public schools is about $50,000. There are also numerous private schools and an academy. There are 11 newspapers published at Portland, 3 of which are daily.—Five railroads which communicate with different parts of the United States and Canada have their termini at Portland, viz.: the Portland, Saco, and Portsmouth, the Kennebec and Portland, the Androscoggin and Kennebec, the York and Cumberland, and the grand trunk, which last extends from Portland *via* Montreal and Toronto to Sarnia, at the foot of Lake Huron, thence connecting with Detroit, a distance of 858 miles. Among the principal manufacturing establishments is that of the Portland locomotive and marine engine building company, which has the machinery to employ 400 workmen; and an extensive sugar house, which boils over 20,000 casks of molasses annually. There are several extensive manufactories of carriages, sleighs, &c. The city is lighted with gas and well supplied with good water, and is considered remarkably healthy. There are 7 banks, with an aggregate capital of $2,650,000, 2 insurance offices, and 2 savings banks, whose deposits amount to $500,000. The foreign trade is chiefly carried on with the West Indies and Europe, the exports being for the most part provisions, lumber, ice, and fish, and the imports molasses, sugar, crockery, salt, and iron. Portland also has a large coasting trade, with regular lines of steamboats running to New York, Boston, Bath, Bangor, Eastport, and St. John, N. B. The Canadian line of European steamers runs weekly from Portland to Liverpool, *via* Londonderry, during the winter months. The total value of the imports in 1859 amounted to $1,668,521, and the exports to $1,221,606. The foreign arrivals for the year were 599 vessels of an aggregate of 120,906 tons, of which 388, of an aggregate of 101,422 tons, were under the flag of the United States. On June 30, 1859, the aggregate tonnage of the port was 115,093, of which 3,969 tons were steam vessels. The registered tonnage consisted of 68,307 tons permanent, and 25,537 temporary; and the enrolled and licensed of 24,841 tons permanent, which were employed as follows: 15,997 tons in the coasting trade, 3,128 in the cod fishery, 1,715 in the mackerel fishery, and 351 tons, licensed under 20 tons, which, with the exception of 34 tons engaged in the coasting trade, were employed in the cod fishery. In the year 1857, 4 ships and barks, 2 brigs, 7 schooners, and 1 steamer, of an aggregate of 3,868 tons, were built.—The Indian name of Portland was Machigonne. An English colony settled here in 1632, but during the subsequent wars with the Indians, French, and the mother country, it suffered very severely, and the town was three times completely destroyed. Portland, which originally formed a part of Falmouth, was incorporated as a town in 1786, and as a city in 1832.

PORTO BELLO. See PUERTO BELLO.

PORTO FERRAJO, the capital of the island of Elba, Italy, on a rocky promontory at the head of a bay, 5 m. S. W. from Cape Vita, on the N. side of the island; pop. about 5,000. It has an excellent harbor, defended by 2 strong forts and several batteries. There are 2 churches, a town hall, barracks, military hospital, and the governor's palace, occupied from May, 1814, till Feb. 26, 1815, by Napoleon.

PORTO RICO, or PUERTO RICO, an island of the Greater Antilles, West Indies, belonging to Spain, extending from lat. 17° 55′ to 18° 30′ N. and from long. 65° 39′ to 67° 11′ W.; extreme length 105 m., breadth 40 m.; area, 3,800 sq. m.; pop. in 1850, 380,000, $\frac{1}{8}$ of whom are slaves. The N. coast is lined with navigable lagoons, and many of the rivers can be ascended for 5 or 6 m. from the sea. There are numerous bays and creeks, but the N. coast is subject to a ground swell which breaks against the cliffs with violence, and none of the harbors except those of Guanica, Hovas, and San Juan are safe at all seasons. A range of mountains runs through the island from E. to W., having a general height of about 1,500 feet above the sea, with one peak of 3,678 feet. In the interior there are extensive plains, and in some places along the coast there are tracts of level fertile land, from 5 to 10 m. wide. Gold, copper, iron, lead, and coal are found; and considerable quantities of salt are procured. The climate, though very warm, is generally considered more healthy than that of any other of the Antilles. The soil is particularly fertile, the proportion of sugar obtained from an equal area being much greater than in any of the other West India islands. The value of the imports during the year 1855 amounted to $5,785,990, and that of the exports to $4,771,715. The trade with the United States in 1858 was as follows: imports, $500,260; exports, $358,402; American vessels entered, 518, out of a total of 1,494.—Porto Rico was discovered by Columbus in 1493, and invaded in 1509 by the Spaniards, who in a few years exterminated the natives, then about 600,000 or 800,000 in number.—The capital, San Juan de Porto Rico (pop. 10,000), stands upon a small island on the N. coast, connected with the mainland by a bridge. It is strongly fortified, and has been three times unsuccessfully and once successfully attacked by the British.

PORTSMOUTH. I. A township and city of Rockingham co., N. H., and the only seaport in the state, situated on the S. side of the Piscataqua river, in lat. 43° 5′ N., long. 70° 46′ W., 3 m. from the sea and 54 m. N. by E. from Boston; pop. in 1860, 9,335. The city stands on a beautiful peninsula formed by the Piscataqua. Among the public edifices are 10 churches (2 Baptist, 1 Christian, 1 Calvinistic Congregational, 1 Episcopal, 2 Methodist, 1 Roman Catholic, 1 Universalist, and 1 Unitarian); an athenæum, which is a handsome 3 story brick building, with a library and cabinets of minerals and objects of natural history; an academy, a state arsenal, 2 market houses, and an almshouse. There are 4 banks with an aggregate capital in 1856 of $691,000, and a savings bank with deposits in January of that year amounting to $836,371. The town is supplied with water from a distance of 3 miles by works constructed by a company formed in 1799. The manufactures are of considerable extent, and include cotton fabrics, hosiery, ale, and beer. The town has also a machine shop and 2 iron founderies, and contains 8 newspaper offices, 18 public schools, including high schools for girls and boys, a marine society, a mechanics' association, and the Howard benevolent society. The harbor can accommodate 2,000 vessels, is particularly safe, and has sufficient depth at low water for the largest class of ships. It is much frequented as a port of refuge, and the rise of the tide and strength of the current keep it free from ice during the severest winters. The principal entrance is between the mainland and the E. side of Great island, and is defended by Fort McCleary on the former, and Fort Constitution on the N. W. point of the latter. The U. S. navy yard is the object of greatest interest at Portsmouth. It is situated on Continental or Navy island, on the E. side of the Piscataqua. It has extensive ship houses, one of which is 300 feet long, 131 wide, and 72 high; large sheds for timber, a rigging loft, machine shop, &c. The balance dry dock is 350 feet long by 105 broad, and has 24 pumps worked by two steam engines. In the year ending June 30, 1860, the exports amounted to $9,605 and the imports to $23,227; 48 vessels of an aggregate of 4,857 tons entered, and 47 of an aggregate of 4,080 tons cleared. The number of vessels built during that year was 6, of an aggregate of 3,846 tons. The shipping belonging to the port in 1860 amounted to 34,485 tons, and many of the ships owned at this port are employed in the trade of other parts of the world. Portsmouth has great facility of communication by railroad with all parts of the surrounding states. It is a station on the eastern Massachusetts railroad, and is connected with numerous other lines by the Concord and Portsmouth railroad. The town was settled in 1623, and incorporated in 1633. It has often suffered severely from fires. II. The capital of Norfolk co., Va., on the W. bank of Elizabeth river, opposite the city of Norfolk, 8 m. from Hampton roads; pop. in 1860, 9,487. It is built on level ground and regularly laid out, and has a court house, a branch of the bank of Virginia, the Virginia literary, scientific, and military academy, 8 newspapers, and 6 churches. By the Seaboard and Roanoke railroad and the James river it has extensive communication, both north and south. (See NORFOLK.) III. The capital of Scioto co., O., on the Ohio river, immediately above the junction of the Scioto, at the terminus of the Scioto and Hocking valley railroad and the Ohio and Erie canal, 115 m. E. by S. from Cincinnati, and 90 m. S. from Columbus; pop. in 1860, 6,268. It has an active business, and regular communication by steamboat with Cincinnati. It contains a bank, 4 private banking establishments, 2 distilleries, 2 rolling mills and iron works, 3 machine shops and founderies, 14 churches, and 5 newspaper offices.

PORTSMOUTH, a fortified town of Hampshire, England, situated on the S. W. extremity of the island of Portsea, 68 m. S. S. W. from London; pop. in 1851, 72,096. It consists of two towns, Portsmouth proper and Portsea, separated from each other by a small creek or arm of the sea crossed by bridges. Both towns are united in one complete fortress surrounded by deep moats and strong walls flanked by regular bastions, the whole defended by a series of outworks. Some of the dwellings are very ancient, and the house in which the duke of Buckingham was assassinated during the reign of Charles I. is still standing in the High street. There are several churches, one of which was originally erected in 1220, and dedicated to St. Thomas à Becket, but the chancel is the only part left of the ancient building. There are extensive barracks for troops of the line. A force of 12,000 men would be necessary to fully man the fortifications, but the usual garrison consists of about 2,500. But the chief importance of the place is derived from the royal dock yard, which is situated at Portsea, to the N. of Portsmouth, and covers an area of 120 acres enclosed by walls. It contains very extensive storehouses for all the materials used in naval architecture, machine shops, extensive slips and docks in which the largest vessels of war are built and repaired, ranges of handsome residences for the port admiral and other officers, and a royal naval college which accommodates 70 pupils. During the Crimean war 4,000 men were constantly employed in the Portsmouth dock yard. Outside the yard an area of 14 acres is occupied by a gun wharf, where vast numbers of guns and quantities of warlike stores are kept. On the mainland opposite Portsmouth, and communicating with it by a steam ferry about ¾ m. across, is the town of Gosport, with a population of 7,500. The channel between these two places forms the entrance to Portsmouth harbor, here defended by South Sea castle on the E. and Monkton fort on the W., and extending several miles between the island of Portsea and the mainland, and gradually widening till it attains a breadth of about 3 m. at its N. extremity. The depth of water is sufficient for vessels of the largest class, and the harbor has the advantage of opening into the fine roadstead of Spithead which is sheltered by the isle of Wight. The only manufactures of importance are those immediately connected with the naval establishments.—The earliest notice of Portsmouth occurs in the "Saxon Chronicle" in 501, where it is called Portsmuthe. During the reign of Alfred a fleet of 9 ships was fitted out at the port, which defeated the Danes; and before the Norman conquest a large number of vessels were sent from it to intercept the invaders. The French landed and burned a great part of the town in 1377, but were ultimately defeated with heavy loss. After this disaster the fortifications were extended and improved, and have continued to receive additions up to the present time. Napoleon sailed from Portsmouth for St. Helena in 1815.

PORTUGAL, a kingdom of Europe, occupying the S. W. part of the Spanish peninsula, bounded N. and E. by Spain, S. and W. by the Atlantic, and extending from lat. 36° 57' to 42° 11' N., and from long. 6° 20' to 9° 49' W.; length from N. to S. about 360 m., greatest breadth about 130 m.; area, 35,400 sq. m.; pop. in 1857, 3,566,895, and of the Portuguese colonies 2,754,380, making the total population of the monarchy 6,321,275. The colonies are the Azores, Madeira, and Porto Santo (though administratively these islands are ranked as component parts of the kingdom), the islands of Cape Verd, Principe, St. Thomas, and Anno Bom on the African coast; some portions of Guinea; Angola and Benguela; Mozambique and its territory; Goa, Daman, and Diu in Hindostan; the islands of Timor and Solor; and the city of Macao in China. The kingdom is divided into 6 provinces, viz.: Entre Minho e Douro, the most northerly, Tras-os-Montes, Beira, Estremadura, Alemtejo, and Algarve, the most southerly province. The capital is Lisbon, and the other chief cities are, in the order of their population, Oporto, Coimbra, Elvas, Braga, Setubal, Evora, and Ovar. None of these except Lisbon and Oporto have more than 20,000 inhabitants.—The coast line is about 500 m. in length, and is not indented by any great bay. At some points it rises into cliffs of considerable height, but the greater part is low and marshy. The principal harbors are those of Lisbon, Oporto, Setubal, Figueira, Aveiro, and Viana. The principal rivers of Portugal flow from Spain, and of these the Tagus, the Guadiana, the Douro, the Minho, and the Lima are the largest. The

Tagus separates the provinces of Beira and Alemtejo, and passing through Estremadura falls into the Atlantic, by a mouth so wide that it is rather an arm of the sea than a river. Its estuary forms the spacious and convenient harbor of Lisbon. The river is navigable to Abrantes, 80 m. above its mouth. Of the rivers which have their whole course in Portugal, the longest are the Mondego, which is navigable for 60 m., the Cavado, Ave, Vouga, Sado, Odemira, Portimao, and Rio Quarteira. In summer these streams become very low, and they are in general much obstructed by rocks and sand bars. There are many lakes on the sea coast, but none of much magnitude. Mineral springs abound, and there are 34 hot springs, many of which are celebrated for their medicinal qualities.—The mountain chains of Portugal are chiefly prolongations in a W. or S. W. direction of the Spanish Pyrénées. Near the N. frontier is a lofty range called the Serra de Montezinho, one of whose peaks, Gaviarra, is 7,850 feet high, and is said to be always covered with snow. The Serra de Gerez, also in the northern provinces, rises where highest 7,360 feet. The Serra d'Estrella, which traverses the province of Beira, is the continuation of a chain from the Spanish provinces of Leon and Castile, and is covered with snow during most of the year; its highest peaks are Cantaro Delgardo and Malao da Serra. A branch of it stretches through Estremadura and terminates at the sea near the mouth of the Tagus, in the promontory called Cabo de Roca or Rock of Lisbon. A prolongation of the great Spanish range of the Sierra Morena encloses the province of Algarve and terminates at Cape St. Vincent; its highest peaks are Foya, 3,840 feet, and Picota, 3,720 feet, near its W. extremity. The mountain scenery of Portugal is exceedingly fine, and few places in the world equal in natural beauty the region around Cintra in the neighborhood of Lisbon.—In its geological character Portugal resembles Spain. Much of the mountainous region of the W. is formed of crystalline rocks. The E. part of Tras-os-Montes, however, consists of slates. A band of crystalline rocks nearly 50 m. broad stretches almost from one end of the country to the other. The district of the upper Douro is formed of slate rocks belonging to the silurian system, and nearly surrounded by granitic and syenitic mountains. In this district is the coal field of Vallongo, which yields anthracite coal. South of Abrantes is a tertiary basin with an area of more than 2,000 sq. m., in which Lisbon stands. To the S. of this basin secondary beds appear, and still further S. between Alemtejo and Algarve is a lofty chain of hills consisting of schists and slates. In the days of the Romans gold and silver were found in Portugal, and gold is still collected from the sands of the rivers, though not in great quantity, the principal mine, that of Adissa near Setubal, yielding an average of 20 lbs. a year. There are mines of lead, plumbago, antimony, copper, and iron, the last named metal being particularly abundant. But from want of enterprise and capital little use is made of the great mineral riches of the country. Beautiful marbles abound, and there are quarries of limestone, gypsum, slate, freestone, millstone, and black agate, together with vast beds of potters' and porcelain clay and of common salt. In 185[illegible] salt was exported to the amount of 35,000,[illegible] bushels.—There is great inequality in the soil of Portugal, but much of the land is exceedingly fertile and well adapted to the growth of all the productions of the temperate zone. The climate among the mountains of the N. is cold and harsh, but on the coast and in the lowlands of the centre it is mild and genial. Lisbon is a place of resort for invalids, and though the southern provinces are exposed to great heats they are not of long continuance, being tempered by breezes from the ocean. Violent storms are very rare, and the cold is never severe except in elevated situations. The vegetation does not differ materially from that of the rest of the peninsula. Among the trees and shrubs are the cork tree and the kermes oak, the bay tree, Portugal laurel, Spanish chestnut, carob tree, myrtle, pomegranate, rosemary, lavender, licorice tree, and in the south various species of palm, the dragon tree, coral tree, the oleander, and the American agave. The orange, the fig, sugar cane, and rice grow luxuriantly, and the wheat, grapes, and olives of Portugal are unsurpassed. Among the wild animals of the country, wolves, wild cats, wild goats, wild boars, and deer are the principal, though none of these are numerous. Venomous serpents abound in the mountains, but are rare in the plains and valleys. There are few birds, the most common being the partridge, and in the mountains vultures and eagles. The coast and the rivers swarm with fish, but the fisheries are carried on so imperfectly that great quantities of salted fish are imported.—The Portuguese are a handsome race, with regular features, olive complexions, and dark, expressive eyes. The reputation of the higher orders is not very good among their neighbors the Spaniards, who have a proverb which says: "Strip a Spaniard of his virtues, and you have a Portuguese;" but unprejudiced observers describe the peasantry as possessed of many noble traits of character, though grievously burdened by oppression and misrule. Agriculture among them is in a very backward condition, the implements used being rude and clumsy, and the whole system of tillage imperfect and unthrifty. The northern provinces are the best cultivated, and their people far more prosperous and intelligent than in the south. The great staples of the country are wheat, wine, and olive oil. The milk chiefly consumed is that of goats. The common bread of the people is made of Indian meal, the soil and climate being both well adapted for the production of maize. Hemp and flax are extensively grown, and beans and other garden vegetables are raised in abundance. Oranges, almonds, and figs are exported. According to the official reports, the average annual agricultural production of the country amounts in value to $40,000,000, the grain being valued at $10,000,000, the wine at $12,000,000, and the wool at $7,000,000. The wines of Portugal have long been celebrated, the most famous being port. (See PORT WINE.) The manufactures of Portugal are not extensive. Woollen cloth is made at Lisbon, Covilha, Portalegre, and Azeitao; cotton goods at Lisbon, Oporto, and Thomar; silk in Algarve; steam engines, iron and tin work, firearms, porcelain, gold and silver work, pottery, candles, and soap at Lisbon, where also there are tanneries, distilleries, and sugar refineries. Wine, oil, salt, wool, fruits, and cork bark are the chief articles of export; and the imports consist principally of the finer kinds of English manufactures, and of coal, tar, pitch, drugs, butter, cheese, and salt fish. The imports in 1854 amounted in value to $20,223,000, and the exports to $15,797,500. About ⅔ of the exports are to Great Britain, and the rest to Brazil, the United States, France, Spain, Russia, Sweden, and Norway. The common roads of Portugal are very bad, and until recently the country was very deficient in means of internal communication. But within a few years two great systems of railroads have been designed and partly completed. One line runs from Lisbon to Santarem, and thence to Oporto, with a branch line to Elvas on the Spanish frontier. Good macadamized roads have also recently been constructed in the provinces N. of the Douro, which in every respect are far in advance of the rest of the country.—The government of Portugal is a limited monarchy under a constitution adopted in 1826. The legislative power is vested in a cortes consisting of two houses, one of peers and the other of deputies; the peers are named for life by the crown, and the deputies chosen by electors, who must have a yearly income of not less than $100. The administration is conducted by 7 ministers, who form the cabinet. In 1856 the titled and hereditary nobility (which is distinct from the house of peers, though nobles may be appointed by the crown to seats in that house) comprised 7 dukes, 21 marquises, 77 counts, 102 viscounts, and 106 barons. For judicial purposes Portugal is divided into 105 districts, in each of which there is a judge, from whose decision there is an appeal to superior courts at Lisbon and Oporto. These judges remain but 6 years at the same place, and are appointed by the crown. Beneath them are inferior classes of judges, who are elected by the people for a term of two years. Trial by jury is established in criminal cases, and also in civil, unless the parties agree to be tried by the judge exclusively. The Roman Catholic is the state religion, and the ecclesiastical establishment consists of a primate, the archbishop of Braga, under whom are 6 bishops; the patriarch of Lisbon, under whom are 3 bishops; and the archbishop of Evora, under whom are 3 bishops. There are also bishops in the colonies of the Azores, Madeira, Cape Verd, St. Thomas, and Angola; and at Goa in India there is an archbishop who has under him 7 bishops and a prelate. All other religions are tolerated, and there are Protestant chapels in Lisbon and Oporto. Public education is under the direction of the minister of the interior, and is managed by a council which holds its sittings at Coimbra. The church has no control over it. By law parents are compelled to send their children to school, but this law is only partially enforced. The only university in the kingdom is that of Coimbra. (See COIMBRA.) The primary schools in 1854 numbered 1,126, attended by 38,000 scholars, of whom only 1,570 were females. The lyceums or schools of the next grade numbered 162, with 2,800 pupils. There are polytechnic academies, medical schools, and academies of fine arts at Lisbon and Oporto; a military college at Mafra; army and navy schools at Lisbon; and agricultural institutes and botanical gardens at Lisbon and Oporto. For the education of the clergy there are 6 seminaries and 8 halls of theology. The finances of the Portuguese government are in a very disordered condition, the expenditures having for a long period exceeded the receipts. In 1860 the receipts amounted to $14,862,000, and the expenditures to $15,782,000. The public debt in 1859 was $120,000,000. The army in 1860 numbered 24,852 men, beside a colonial force of about 18,000, stationed chiefly in Africa and the East Indies. The navy comprised 40 sailing vessels and 16 steamers, manned by a force of 3,698 men.—Portugal was inhabited anciently by Celtic tribes, and was early visited for commercial purposes by the Phœnicians, Carthaginians, and Greeks. The Romans, who called it Lusitania, from its chief tribe the Lusitani, effected its final subjugation about 140 B. C., and held it as a province till the 5th century of the Christian era, when it was overrun by the Visigoths and other northern barbarians. In the 8th century it was conquered by the Arabs, from whom it was partly recovered toward the close of the 11th century by Alfonso VI., king of Leon and Castile. About the year 1095 Alfonso gave the country between the Minho and the Douro to his son-in-law, Henry of Burgundy, who took the title of count of Portugal, and soon extended his dominions by conquests from the Arabs or Moors. He died in 1112, and was succeeded by his son Dom Alfonso, who in 1139 defeated the Moors in a great battle on the plains of Ourique near the Tagus. From this battle the Portuguese date the foundation of their kingdom, Dom Alfonso having been proclaimed king by his army on the field of victory. His son and successor, Dom Sancho I., was equally successful in the struggle with the Moors, and by his valor and abilities raised Portugal to a high pitch of prosperity and power, and extended its area to its present dimensions. Of his successors the most distinguished was John I., surnamed the Great, who began his reign in 1385. He repelled a formidable invasion of the Castilians, led a successful expedition against the Moors of Barbary, and acquired possession of Madeira and the Azores, which were discovered during his reign. He died in 1433. The Portuguese at this period were the most enlightened and enterprising people of Europe, and their efforts to enlarge the scope of geographical knowledge toward the south led them to undertake daring and difficult voyages along the coast of Africa, which for half a century were ably and perseveringly directed by Prince Henry the navigator, the third son of John the Great. These attempts were at length crowned with success by the achievement of a passage to the East Indies round the Cape of Good Hope by Vasco da Gama in 1497. This was in the reign of Dom Emanuel the Fortunate, under whose intelligent guidance prodigious efforts were made to extend the commerce and the dominion of Portugal in Africa and the East. In the latter region their power was exercised by a succession of able viceroys, among whom Alfonso d'Albuquerque was particularly eminent. For nearly a century the Portuguese were masters of the Indian ocean, and the dominant power on the E. coast of Africa and the S. coast of Asia. In 1501 Brazil was discovered by a Portuguese adventurer, and John III., who ascended the throne in 1521, made great efforts to colonize it. He died in 1557, and was succeeded by his son Dom Sebastian, who distinguished himself by Quixotic expeditions against the Moors of Barbary, in one of which, in 1578, he perished with all his army. This disaster effectually broke the power of Portugal. Dom Henry, the uncle of Sebastian, ascended the vacant throne, and on his death in 1580 without direct heirs, the crown was claimed by Philip II. of Spain, the prince of Parma, and the duchess of Bragança. The power of Philip decided the contest in his favor, and for the next 60 years Portugal was a part of the Spanish monarchy. For a considerable period the peace of the country was disturbed by pretenders claiming to be Dom Sebastian, whom the common people believed to have escaped the swords of the Moors and to be living in a mysterious seclusion, from which he was to reappear for the redemption of Portugal. The rule of the Spanish kings bore heavily on Portugal, and in 1640 the nation rose in revolt, and by an almost unanimous voice proclaimed the duke of Bragança king, under the title of John IV. A long war with Spain ensued, which was terminated in 1665 by the decisive defeat of the Spaniards in the battle of Montesclaros. Amicable relations, however, were not fully restored between the two nations till 1737, in the reign of John V., an able and successful monarch, who died in 1750. Under his son and successor Joseph I., Portugal experienced many calamities, the most remarkable of which was the great earthquake which destroyed one half of Lisbon in 1755. This reign, however, was marked by great social and agricultural reforms, carried out chiefly by the genius and energy of the king's prime minister, the famous marquis of Pombal. Joseph was succeeded in 1777 by his daughter Maria, who became insane in 1792, and continued so till her death in 1816, her son John, prince of Brazil, acting as regent. During her reign in 1807 Portugal was conquered by a French army under Marshal Junot, by order of Napoleon, who had declared the house of Bragança to have forfeited the throne by the refusal of the prince regent to confiscate English merchandise in his dominions. The royal family embarked for Brazil and continued at Rio Janeiro till 1821, though by British assistance the French were expelled in 1812. In 1820 the dissatisfaction of the people at the absence of the court, and a general feeling that fundamental changes were required in the constitution, led to a revolution unattended by violence or bloodshed, the army and the people acting in concert. A liberal constitution was adopted, and in 1821, at the request of the nation, John VI. returned from Brazil, leaving his eldest son Dom Pedro there as regent. In the following year Dom Pedro was proclaimed emperor of Brazil, and the two countries were finally separated. John VI. died in 1826, and Dom Pedro of Brazil, the legitimate successor, surrendered Portugal to his daughter Maria, and established a new and tolerably liberal constitution for the kingdom. Before Maria arrived in Portugal, her uncle Dom Miguel, Pedro's younger brother, who had been appointed regent, usurped the throne, and began to rule without regard to the constitution. His despotism provoked a civil war, which raged for several years, and was finally terminated in 1834 by the triumph of the liberals, the expulsion of Miguel, and the establishment of Maria on the throne. Several revolutions and counter revolutions have since taken place, the principal result of which has been the substitution of one faction for another in the control of the royal ministry. The most serious of these outbreaks, that of 1846–'7, was provoked by the unpopularity of the ministry of Costa Cabral, the count of Thomar, and but for British, French, and Spanish intervention would have overthrown the government. The queen Maria died in 1853, and her eldest son Pedro V. succeeded, and is now reigning (June, 1861).

PORTUGAL, Language and Literature of. The language of the Lusitani is unknown, for at an early period it gave place to the Latin, which continued to be spoken in Portugal in comparative purity for about 6 centuries. The northern barbarians then infused into it a Gothic element, and the compound thus formed was still further corrupted 3 centuries later by a Semitic admixture. During the Moorish rule Arabic was the language generally spoken by the higher classes, and João de Souza in 1789 enumerated no fewer than 1,400 words which the Portuguese had borrowed from the Arabic and other eastern languages. The influence of the Arabic was succeeded; though its effect was not destroyed, by that of the idioms of the different foreign auxiliaries, French and others, who assisted the Portuguese in driving out the Moors. The Portuguese is thus one of the modern forms of the Romance language. It bears a remarkable affinity to the Galician, being readily understood by the Gallegos; and a less marked similitude to the Catalan. The pronunciation, though difficult for foreigners, is free from the guttural sounds which abound in Spanish, and the harsh aspirates which it might be expected to have borrowed from the Gothic and Arabic. The French nasal sounds *an*, *in*, *on* occur frequently, and the letters *j* and *ch* are also pronounced very much as in French. The peculiar diphthong *ão*, as in the termination *cião* (Fr. and Eng. *tion*) and elsewhere, is pronounced nearly like *owng* in English. The Portuguese is less sonorous and majestic than the Spanish, but more fluent, sweeter, and simpler. Sismondi called it "a boneless Castilian" (*un Castillan désossé*); the Spaniards on the other hand have styled it a language of flowers. The Latin words which form the basis of the Portuguese have undergone more changes than they have suffered in any other modern tongue. Some radical letters are almost always omitted, the consonants *l* and *n* being most frequently dropped; thus, Lat. *dolor*, Port. *dor;* Lat. *ponere*, Port. *pôr;* Lat. *populus*, Port. *povo;* Lat. *ille*, *illa*, Port. *o*, *a;* Lat. *pater*, Port. *pay*. The grammar is in general simple, the only peculiarity which deserves particular notice being the inflections of the infinitive mood of the verb, which beside the ordinary impersonal form has a personal form governed by a noun or pronoun; thus, *amar*, to love; *o eu amar*, to love me; *o tu amares*, to love thee. See Constancio, *Grammatica analytica da lingua Portugueza* (Paris, 1831), and *Nouvelle grammaire Portugaise* (1832); and Fonseca, *Éléments de la grammaire Portugaise* (1832). There are dictionaries by Da Costa and Sa (Portuguese, French, and Latin, Lisbon, 1794); Da Cunha (French and Portuguese, Lisbon, 1811); and Vieyra (English and Portuguese, new ed., London, 1840).—Portuguese literature comprises few works of any note except poems and histories. The earliest compositions of which we have any knowledge, dating from about the commencement of the 12th century, were imitations of the French troubadours. Some of the songs of Gonçalo Henriques and Egaz Moniz Coelho, gentlemen of the court of King Alfonso I., are still extant, and prove the existence of lyric poetry in Portugal two centuries earlier than in any other province of the peninsula. During the 13th and 14th centuries the poetic art was fostered by the example of several princes, such as King Denis, his natural son Alfonso Sanches, King Alfonso IV., King Pedro I., and the infante Dom Pedro, son of John I. At the same time the romances of chivalry had been diligently cultivated, especially by Vasco de Lobeira, the reputed author of "Amadis de Gaul." During the 15th century, which has been called the heroic age of Portugal, prose compositions became both more numerous and more important. Fernand Lopez, the Portuguese Froissart, Gomez Eannes de Azurara, another chronicler, and King Alfonso V., who wrote a treatise on the art of war and a little work on astronomy, are among the most noteworthy names of this period. King Edward (died 1438) composed a treatise *De Bono Regimine Justitiæ*. Damião de Goes is known as the author of a Latin treatise *De Moribus Ethiopum* and a chronicle of King Emanuel. A much higher reputation belongs to Bernardino Ribeyro (about 1500), an officer of the household of King Emanuel, who entertained a hopeless passion for the daughter of his sovereign, and told his grief to the woods and mountains in verses chiefly remarkable for overstrained sentiment and obscurity. He was more successful in other kinds of composition, and his pastoral romance *Menina e moça* ("Small and Young," so called from the words with which it begins) is the earliest example of a good Portuguese prose style. He contributed greatly to the popularity which pastoral poetry and romance acquired about this time in Portugal as well as in other parts of Europe. Of the pastoral authors contemporary with Ribeyro, Christovão Falção is the only one who deserves separate notice. The classical school of poetry was inaugurated by Saa de Miranda (died 1558), a versatile author, who like most of the poets of his country wrote in both Portuguese and Castilian; he left pastorals, sonnets, hymns, songs, ballads, epistles in verse after the manner of Horace, and two comedies, *Os estrangeiros* and *Os Vilhalpandios*. Another of the classical poets is Antonio Ferreira (died 1569), remarkable for good taste, simplicity, and correctness. His best works are his epistles, beside which he left sonnets, odes, and elegies, and a drama on the subject of Ines de Castro, constructed after the ancient Greek fashion. The maritime expeditions of this period soon opened a new field in which poets, historians, soldiers, and navigators equally found occupation. The exploits of Vasco da Gama were recounted by Fernam Lopez de Castanheda, who wrote a history of the discovery of the Indies. Mendez Pinto published an account of his extraordinary adventures, Galvão wrote his travels in Abyssinia, Francisco Alvares an account of Ethiopia, and Alfonso d'Albuquerque his "Commentaries." The chief however of the historians of this epoch was João de Barros, whose *Asia Portugueza*, continued by Couto (14 vols. fol., 1552–1615), is the first great work containing an authentic narrative of the conquests of his countrymen both in the Indies and the African seas. His style, though somewhat involved, is distinguished by purity of diction, and his descriptions are remarkably life-like. In a far more attractive garb are the adventures of Da Gama presented by Camoëns (1524–'79), the only poet of Portugal, as Sismondi observes, whose celebrity has extended beyond the peninsula. His great epic, "The Lusiad" (*Os Lusiadas*, the Lusitanians), was the first poem of the kind in any modern tongue. Its professed object was to relate the glorious deeds of the Portuguese in every age, but the greater part of it is devoted to their achievements in India. In his shorter poems Camoëns is the model of nearly all his countrymen after him. A contemporary of Camoëns was the dramatist Gil Vicente, the chief Portuguese author in a department of literature in which Portugal is remarkably deficient. He wrote *autos*, or miracle plays; comedies which are little more than novels in dialogue, totally devoid of plot and climax; tragi-comedies, rude and undeveloped; and farces which display much humor and discrimination of character. He flattered the popular taste by lugging shepherds into all his plays, and the mania for bucolics became stronger after his death than it had ever been before. Rodriguez de Lobo, an author of the latter half of the 16th century, wrote three extravagant pastoral romances entitled *Primavera* ("Spring"), *O pastor peregrino* ("The Wandering Shepherd"), and *O desenganado* ("The Disenchanted Lover"), scattered through which are some charming bits of poetry. Jeronymo Cortereal (died about 1593) is the author of an epic on the adventures of Manoel de Sousa Sepulveda, shipwrecked on the coast of Africa, and another on the "Siege of Diu." The *Ulyssea* of Pereira de Castro, and the *Malacca conquistada* of Francisco de Sa y Menezes, rank high in the opinion of Portuguese critics. Bernardo de Brito (died 1617) undertook a history of the kingdom, under the title of *Monarchia Lusitana;* but, commencing at the creation of the world, death overtook him when he had just reached the establishment of the Portuguese monarchy. Manoel de Faria e Sousa (died 1649) once enjoyed a brilliant reputation, but the quantity and variety of his works are more remarkable than their excellence. Antonio Barbosa Bacellar (died 1663) introduced those amorous and melancholy soliloquies called *Saudades*. Jacinto Freire de Andrada (died 1657), a writer of burlesque poetry, was also admired for an elaborate and affected "Life of João de Castro" in prose. The Jesuit Vieira (died 1697), surnamed the Lusitanian Cicero, is one of the most eloquent of Portuguese prose writers. Strained conceits and extravagant phraseology are the principal characteristics of the writings of Violante do Ceo (died 1693), a Dominican nun who left a great amount of sacred and profane verse. Jeronymo Bahia is notable as one of the many poets who chose for their theme the loves of Polyphemus and Galatea, a subject which Andrada burlesqued with much humor. The honor of producing one of the most natural poets of the time belongs to the island of Madeira, the birthplace of Francisco de Vasconcellos. Andrea Nuñez de Sylva, the author of excellent devotional verses, was a native of Brazil. Francisco Xavier de Menezes, count of Ericeyra (died 1743), celebrated the exploits of Henry of Burgundy in a correct and spiritless epic entitled the *Henriqueida*. Antonio José, the author of coarse but sprightly comic operas, bade fair to revive the Portuguese drama when the inquisition burned him for a Jew in 1745. Antonio Correa Garção (died 1772) wrote several comedies in imitation of Terence, and the count of Vimiero produced in 1788 *Osmia*, the only genuine tragedy in the language. João Anastasio da Cunha (died 1790), a distinguished mathematician, was also a poet of no mean rank. Araujo de Azevedo translated Dryden, Gay, and some other English poets. Francisco Manoel do Nascimento (died 1821) was noted for the dignity and boldness of his lyric verses, and Antonio Dinis da Cruz e Silva, beside imitations of English poetry, composed numerous odes and sonnets. The chief authors of the more recent period are Manoel de Barbosa Boccage (died 1806), Francisco Diaz Gomez, Francisco Cardoso, Alvarez de Robriga, Xavier de Matos, Valladares, Tolentino de Almeida, Antonio de Castilho, a translator from the English; Garret, a poet, romancer, and dramatist; Hercules de Carvalho, a patriotic and religious poet; and Luiz da Silva Mouzinho de Albuquerque, a statesman and the author of georgics.—In Brazil literature within the last few years has made more rapid progress than in Portugal. Beside the poems of Claudio Manoel da Costa, we may mention the *Historia general do Brazil* (1854) of Varnhagen, Brazilian chargé d'affaires at Madrid; the "Brazilian Plutarch" of Pereira da Silva; the sermons and compendium of philosophy of Mont'alverne; the "Chorography of Brazil" of Mello Moraes, the translation of Virgil by Mendes; and the poems of Gonçalves Diaz, Macedo, Abreo, and Magalhaens. The last named author has also written a tragedy on the fate of Antonio José, and a philosophical and physiological work entitled *Os factos do espirito humano* (1859).

PORTUGUESE MAN-OF-WAR. See Jelly Fish.

PORTULACA. See Purslane.

PORUS, the Greek form of the names of several kings of India, two of whom were met by Alexander in his conquest of the East. The first ruled on the west so far as the Hydaspes, and when the Greeks attempted to cross that river, he prepared to dispute its passage at the head of a large force, and with more than 200 trained elephants. Alexander finally succeeded in eluding his vigilance, and forded the stream higher up. The battle that ensued was fought with desperate bravery on both sides, but the superior generalship of Alexander finally prevailed. Porus, who had maintained his ground to the last, was forced to flee after seeing two of his sons slain and being himself erely wounded. He was captured and ught before Alexander, who, struck by his rage and manly bearing, asked him what wished should be done for him. "That should deal with me as a king," said Po-. He was honorably treated by the Macenian monarch, and became his ally, accompying him in several expeditions. Alexander arged his dominions, so that they extended m the Hydaspes to the Hyphasis, and were d to include 7 nations and more than 2,000 ies. He was treacherously put to death Eudemus, who was left commander of the eek troops in that region. It is said that he s 5 cubits in stature.—His cousin of the same me ruled at the same time over Gandaris, of the Hydraotes. He fled on the approach Alexander, and his dominions were given to kinsman, to whom he had previously been stile.

POSEIDON. See NEPTUNE.

POSEN, a province and grand duchy of russia, bounded N. by West Prussia, E. by land, S. by Silesia, and W. by Brandenburg; ea, 11,568 sq. m.; pop. in 1858, 1,417,155. It as a very flat surface, abounding in lakes and arshes, and drained by a large number of reams, the principal of which are the Warta, branch of the Oder, intersecting it a little S. f the centre, and its affluent the Netze, which ows through the N.; the Vistula touches its N. E. border, and a branch, the Brahe, traverses a small portion of the same corner. Of the lakes the largest are the Goplo, Powidz, Sletsk, and Biala. The soil is generally very roductive; in some places it is light and sandy, ut most of it susceptible of cultivation, and the climate is temperate and healthy. It is e of the principal agricultural provinces of Prussia, and the forests supply large quantities of timber, much of which is exported. There are manufactories of woollen stuffs, linen, and leather, beside 203 breweries and 357 distilleries. The bulk of the population nsists of Poles, professing the Roman Catholic religion. Germans and Jews are numerous in the towns, the principal of which are, beside the capital, Bromberg, Gnesen, Lissa, Krotoschin, and Fraustadt.—Formerly this province formed part of Poland, but on the first partition of that kingdom in 1772 that part N. of the Netze was taken by Prussia, and at the second partition in 1793 it obtained the remainder. In 1807 it was incorporated by Napoleon with the duchy of Warsaw, but by the treaty of Vienna it was restored to Prussia. An insurrection concerted by the leaders of the emigrant Poles, and of which Mieroslawski was to have command, was suppressed in 1846, and the chiefs imprisoned until 1848, when they were liberated in consequence of the Berlin revolution. In the latter year it was, after an insurrection and severe struggle under Mieroslawski, united with the German confederacy, and separated in 1851 by treaty. It is divided into the districts of Posen and Bromberg.—Posen (Pol. *Poznan*), the capital, is a strongly fortified city on the river Warta, at the junction of the Glowna, in a sandy plain, 149 m. E. by S. from Berlin; pop. in 1852, 44,029. It is surrounded with a mound and ditch, and is protected by 6 forts, one of which, Fort Winiary, is of great strength. The city is entered by 4 gates, and has a town hall, built in the 16th century. There are a number of churches, a synagogue, several convents, a theatre, 2 gymnasia, a college, hospitals and asylums, and several schools. Linen, woollen, calico, leather, tobacco, &c., are manufactured. On the opposite side of the river is Wallischei, a suburb, in which is an old cathedral containing many ancient monuments. Posen became a bishopric in the 10th century, and in the 13th was the residence of the dukes of Poland.

POSEY, a S. W. co. of Ind., forming an extremity of the state, separated S. from Ky. by the Ohio and W. from Ill. by the Wabash river; area, about 400 sq. m.; pop. in 1860, 16,185. It has an undulating surface, a very fertile soil, composed in part of extremely rich bottom lands, and an abundance of coal. The productions in 1850 were 895,704 bushels of Indian corn, 21,245 of wheat, 30,259 of oats, and 17,667 lbs. of wool. It contained 6 saw mills, 2 tanneries, 1 newspaper office, 16 churches, and 1,000 pupils attending public schools. Capital, Mount Vernon.

POSIDONIUS, a Greek stoic philosopher, born in Apamea in Syria, probably about 135 B. C., died about 51. He studied philosophy at Athens under Panætius, visited Spain, Italy, Gaul, and Illyricum, and finally settled in Rhodes, where he became the head of the stoic school, was elected *prytanis*, and in 86 was sent as ambassador to Rome. He gave instruction to Cicero while the latter was in Rhodes, and was on friendly terms with Pompey, by whom he was twice visited. In 51 he removed to Rome, where he soon afterward died. None of his works have come down to us entire; the fragments extant were collected and published by James Bake under the title of *Posidonii Rhodii Reliquiæ Doctrinæ* (Leyden, 1810).

POSITIVISM, or POSITIVE PHILOSOPHY. See COMTE.

POSSE COMITATUS (Lat., the power of a county), the force of able-bodied male persons between the ages of 15 and 70, whom the sheriff by the common law is authorized to call to his assistance in case of invasion, rebellion, riot, breach of the peace, forcible resistance to process, &c., in the county or district in which he holds office. All persons included in the posse comitatus are bound, under penalty of indictment, to assist the sheriff when lawfully called upon, and are justified in killing a person in case of resistance. Unnecessary violence on their part, however, is punishable.

POST, a public establishment for the conveyance of letters, newspapers, &c. The Assyrian and Persian monarchs had their posts placed at stations a day's journey from each other, with horses saddled, ready to carry with the utmost despatch the decrees of the despot. In the Roman empire couriers on swift horses passed from hand to hand the imperial edicts to every province. Private letters were sent to their destination by slaves, or intrusted to casual opportunities. Charlemagne, it is said, established stations for couriers, who delivered small packets, letters, and decrees, from the court to every part of the realm; but after his death these stations were abandoned, and special messengers sent only when occasion demanded. In 1464 Louis XI. revived the system of mounted posts, stationing them at distances of 4 French miles apart, and requiring them to be ready night and day to carry government messages as rapidly as possible. Similar posts, the riders of which were called *nuncii*, were established in England in the 13th century. These were however exclusively for the transmission of government despatches. As late as the 15th century, butchers or drovers, who went about buying cattle, were the principal carriers of private letters. The only exception to this general custom in regard to private correspondence was the establishment in the 11th century, by the university of Paris, of a body of pedestrian messengers, who bore letters from its thousands of students to the various countries of Europe from which they came, and brought to them the money they needed for the prosecution of their studies. The great development of commerce following the crusades, and the geographical discoveries of the Italians, Portuguese, and Spaniards, created a necessity for business correspondence about the beginning of the 16th century. The royal *nuncii*, or post riders, had already found it for their advantage to use their surplus horses for the conveyance of passengers, and thus the system of posting, or travelling with post horses, came into vogue. These posts were now used for the carriage of private letters, at first irregularly, and without fixed compensation or regular periods of arrival or departure, but eventually with considerable order and system. The earliest of these posts for general accommodation in Europe was established in 1516 in the Tyrol, connecting Germany and Italy, by Roger, count of Thurn and Taxis. His successors received from the emperors of Germany repeated enfeoffments of the imperial post, and extended it over the greater part of Germany and Italy. Venice, Genoa, Leghorn, and Naples were thus connected with Hamburg, Bremen, Lübeck, and Frankfort-on-the-Main, and the active commerce which had sprung up between these cities was greatly facilitated. The counts of Thurn and Taxis retained this postal monopoly till the fall of the German empire, and even now the Thurn and Taxis post is maintained in 10 or 12 of the smaller German states, and supplies a district of 25,000 square miles and nearly 4,000,000 inhabitants. In 1524 the French posts, which had hitherto only transmitted the letters and messages of the king and nobles, were permitted to carry other letters. In 1581 Thomas Randolph was appointed chief postmaster of England, but his functions seem to have pertained more to the establishment and supervision of post houses, and the regulation of the fees for posting, than to the transmission of letters. In Peru, in 1527, the Spanish invaders found a regular system of posts in operation along the great highway from Quito to Cuzco, and messages as to the progress of the invasion, as well as other subjects, were forwarded to the inca by fleet-footed runners, who wound around their waists the *quipu*, a species of sign writing by means of knotted cords.—The complete organization of a system of postal communication in England did not take place till the reign of James I., who soon after his accession constituted the office of postmaster of England for foreign parts, and appointed Matthew Le Quester the first postmaster, with reversion to his son. Le Quester appointed William Frizell and Thomas Witherings his deputies. The latter eventually became postmaster-general, and in 1635 was ordered to establish a running post between London and Edinburgh, to go night and day, and come back in 6 days. In 1644 Edmund Prideaux, then a member of the house of commons, was appointed master of the posts, and first established a weekly conveyance of letters into all parts of the nation. In 1656 an act was passed to settle the postage of England, Scotland, and Ireland, fixing the rates of letter postage and the prices for post horses. The rates of postage previous to this act were for a single piece of paper: under 80 miles, 2*d.*; between 80 and 140 miles, 4*d.*; above 140, 6*d.*; and on the borders and in Scotland, 8*d.* The act of 1656 raised these rates (which were in all cases for a single letter) to 14*d.* for a distance of more than 800 miles, from which sum they were diminished according to the distance down to 2*d.* for 7 miles and under. Between this period and 1838 more than 150 acts relative to postal affairs were passed, but the rates of postage were not materially changed. These rates operated as an almost prohibitory tariff on letters through the mails, and all manner of devices for avoiding the payment of postage were adopted. The franking privilege, which at an early period had been granted to members of parliament and officers of the government, was much abused. Franks were sold openly. In 1838 the franked and privileged letters amounted to 30 per cent. of the whole number transmitted through the mails. In 1784 the net revenue of the post office did not exceed £150,000; but by the introduction of fast mail coaches soon after that date, it had risen in 1815 to about £1,600,000, at which point it remained stationary for more than 20 years, in consequence of the abuse of the franking privilege, and the methods adopted to evade the payment of postage. In 1837 the number of letters annually sent through the mails was 82,000,000; in 1859 it had risen to 545,000,000.

This extraordinary increase is the result of the entire change in the rates of postage, and the greatly improved facilities for the prompt transmission and delivery of letters, first proposed by Rowland Hill in 1837. Mr. Hill, who was not then connected with the post office department, broached his plan in a pamphlet on post office reform; it was adopted by parliament in 1839, and went into operation in 1840, under the supervision of its originator. Its principal provisions were: the reduction of all inland postage to a uniform rate (1*d.* for a single half ounce); the weight of a letter, and not the number of pieces, to form the basis of the rate; the entire abolition of the franking privilege; the despatch of the mails at more frequent periods; and increased speed in the delivery of letters. To these were subsequently added payment by stamps and prepayment. In 1848 the transmission of books by post was granted, at first at 6*d.* per lb. This was subsequently modified so as to give increased facilities for forwarding proofs, pictures, and indeed every thing except manuscripts and letters, at low prices. The rates to the colonies are also such as to encourage the transmission of letters and small packages thither by mail. Letter postage is 6*d.* per ½ oz. to the colonies; small packages, not letters, 3*d.* for 4 oz., 6*d.* for 8 oz., and 6*d.* additional for every 8 oz. or fraction thereof. These rates are increased ½ on packages or letters sent to Australia, New Zealand, Ascension island, or British India or China. The money order system, *i. e.*, granting certificates by the postmasters for a small percentage for sums under £5, payable by any other postmaster, was adopted in 1840; it was copied from the German post office system, where it had long been in practice. At first 5 per cent. was charged for these orders; but in about a year the commission was reduced to 3*d.* for sums under £2, and 6*d.* for sums under £5, and at these rates the amount remitted in the United Kingdom in 1859 was £13,230,930. In 1855 pillar letter boxes were introduced, and London was divided into 10 districts, for greater facility in the distribution of city letters. At first, under the new postage law, the English post office department did not pay expenses; but its net revenue has been gradually increasing, and is now considerably greater than under the old system. The number of persons connected with the postal service in England is about 25,000, of whom 6,000 are employed in the London district.—In France the carriage of letters and newspapers was farmed out, like most of the other sources of state revenues, from 1676 to 1791. The leases were for 6 years, and the rates of postage fixed. The revenue to the government rose, during that period, from 1,400,000 to 10,800,000 francs ($270,200 to $2,084,400) per annum. In 1791 the management of the department was resumed by the government, and variously modified during the revolution and the different governments which followed. Uniform rates of postage for inland and city letters were adopted in 1849, as follows: for letters within Paris, 2 sous (2 cents nearly) when the weight is under 15 grammes (not quite half an ounce), 4 sous if over 15 and under 30 grammes, &c.; for letters to or from other parts of France, Algeria, and Corsica, 4 sous if under 15 grammes, &c. If not prepaid, one half is added to these rates. Newspapers must always be prepaid, but throughout France the postage is only 1 sou, and if treating on questions of political or social economy only half that price. For foreign countries, the weight prescribed for single postage is 7½ grammes, or about ¼ oz. In 1859 the total number of French post offices was 3,703; the total number of persons employed in the postal service was about 28,000. In 1831 the receipts were 24,000,000 francs ($4,752,000); in 1859, 58,308,000 francs ($11,256,444). The number of letters conveyed by post in France in 1859 was 259,450,000; 90 per cent. of the whole number were prepaid.—In the English colonies which subsequently became the United States, a postal system was projected as early as 1692; but owing to the thinness of the population, it was not organized till 1710. By act of parliament of that year, the postmaster-general of the colonies was "to keep his chief letter office in New York, and other chief offices, at some convenient place or places, in other of her majesty's provinces or colonies in America." The revenue was for some years very small. In 1753 Benjamin Franklin was appointed postmaster-general for the colonies, and was guaranteed the sum of £600 per annum for the salary of himself and his assistant. He brought his usual executive ability to the work of remodelling and extending the operations of the office, and in a few years materially increased its revenues. He startled the people of the colonies in 1760 by proposing to run a stage wagon, to carry the mail from Philadelphia to Boston, once a week, starting from each city on Monday morning and reaching its destination by Saturday night. In 1774, while in England, Franklin was removed from office by the British government, in consequence of his exposure of the duplicity of Governor Hutchinson of Massachusetts, and his adherence to the cause of the colonies. In 1789 the constitution of the United States conferred upon congress the exclusive control of postal matters for all the states; and congress proceeded, immediately upon the adoption of the constitution, to organize the post office department, and to pass the necessary laws for the protection of the mails, &c. In 1790 there were but 75 post offices in the country, and the whole amount of postage received was $37,935, yielding a net revenue of $5,795 to the government; in 1800 the number of post offices had increased to 903, the amount of postage to $280,804, and the net revenue to $66,810. The rates of postage from the organization of the department until 1816 were: for a single letter (that is, one composed of a single piece of paper), under 40 miles, 8 cts.; under 90, 10 cts.; under 150, 12½ cts.; under 300, 17 cts.; under 500, 20 cts.; over 500, 25 cts. In 1816 these rates were modified as follows: A single letter carried not over 30 miles, 6¼ cts.; over 30 and under 80, 10 cts.; over 80 and under 150, 12½ cts.; over 150 and under 400, 18¾ cts.; over 400, 25 cts.; and an additional rate for every additional piece of paper, and if the letter weighed an ounce, 4 times these rates. Newspapers under 100 miles, or within the state where published, 1 ct.; over 100, and out of the state, 1½ cts.; magazines and pamphlets, 1½ cts. per sheet, under 100 miles, if periodicals; over 100, 2½ cts. per sheet; if not periodicals, 4 and 6 cts. As the facilities for transportation of the mails by steamboats, railroads, &c., increased, these high rates occasioned much dissatisfaction, and in various ways the law was evaded, and the postal revenue thus reduced. For several years letters were carried in large numbers by express between the principal cities, at rates much below those of the post office. The revenue reached its highest point in 1840 and 1842, being in the former year $4,539,265, and in the latter $4,546,246. From this point it receded. Even with this revenue the establishment did not pay expenses, there being a deficiency every year subsequent to 1837. The subject of a reduction of rates was repeatedly broached in congress, and measures for that purpose were proposed by Mr. Edward Everett in 1836; but no well digested plan was brought forward. In 1843 the general discontent of the people on the subject was expressed in the form of resolutions by the legislatures of several states, instructing their senators and requesting their representatives in congress to take some measures for a reduction. Mr. C. A. Wickliffe, at that time postmaster-general, made some investigation in regard to the English system, and in an elaborate report advocated some reduction, but not a radical one, on the ground that the department would become a heavy charge upon the government if a large reduction were made. A bill was drafted reducing the rates to 5, 10, and 15 cents for different distances; this bill passed the senate, but was lost in the house; the next year it was again brought forward, but again failed. In the next congress a new bill was presented, which became a law, March 3, 1845, and went into operation on July 1, 1845. Its rates were: For a letter not exceeding ½ oz. in weight, whether of one or more pieces of paper, under 300 miles, 5 cts.; over 300, 10 cts.; and an additional rate for every additional ½ oz. or fraction of ½ oz. Advertised letters, 2 cts. additional; drop letters, 2 cts.; circulars unsealed, 2 cts.; pamphlets, magazines, &c., per oz. 2½, and each additional oz. 1 ct. Newspapers under 30 miles, free; over 30 and under 100, or any distance within the state where published, 1 ct.; over 100, and out of the state, 1½ cts. Carriage by express was prohibited, unless the postage was previously paid. In the next congress an effort was made to raise these rates, as the postal revenue did not defray expenses; it was unsuccessful in regard to letter postage, but transient newspapers were charged 3 cts., and prepayment required: the postage on circulars was raised to 3 cts.; newspaper postage to Oregon and California was fixed at 4½ cts., and letter postage to the Pacific territories, *via* Chagres and Panama, at 4 In 1849 the postage on transient newspapers was reduced to ordinary newspaper rates, but prepayment still required. In 1851 another effort was made to raise the postage, which proved unsuccessful; but a law was passed establishing the following rates: For a single letter (of ½ oz. weight) under 3,000 miles, if prepaid, 3 cts., or if not prepaid, 5 cts.; over 3,000 miles, 6 or 12 cts.; to foreign countries, over 2,500 miles, except where postal arrangements have been made, 10 cts.; over 2,500 cts.; drop letters, 1 ct.; ship letters, 2 cts.; if delivered where deposited, 6 cts.; if sent through the mails, the ordinary postage is added. Weekly newspapers, to actual subscribers in the county where published, free; under miles and out of the county, 5 cts. per quarter; over 50 and under 300, 10 cts.; over 300 and under 1,000, 15 cts.; over 1,000 and under 2,000, 20 cts.; over 2,000 and under 4,000, cts.; over 4,000, 30 cts. Monthly papers and semi-monthly ½ these rates; semi-weekly double, tri-weekly treble, and oftener than tri-weekly 5 times these rates; newspapers under 300 square inches, ¼ these rates; if paid quarterly in advance, a deduction of one half to be made from these rates. Transient newspapers, circulars, and other printed matter, 1 ct. per oz. under 500 miles; over 500 and under 1,500, 2 cts.; over 1,500 and under 2,500, 3 cts.; under 3,500, 4 cts.; over 3,500, 5 cts. Books under 32 oz. in weight, 1 ct. per oz. if prepaid; if not, 2 cts. per oz. In 1852 the following modifications were made: Letters sent over 3,000 miles, and not prepaid, 10 cts. postage; newspapers, circulars, &c., under 3 oz., 1 ct. every additional oz. or fraction, 1 ct.; small newspapers and periodicals, published monthly or oftener, and pamphlets of not more than octavo pages, sent in single packages of not less than 8 oz., prepaid, ½ ct. per oz., or if not prepaid, 1 ct. Books, bound or unbound, less than 4 lbs., under 3,000 miles, 1 ct. per oz.; over 3,000, 2 cts. per oz.; 50 per cent. added when not prepaid. By the act of the same year, postage stamps and stamped envelopes were ordered. By a law passed March 3, 1855, and taking effect July 1 of the same year, the rates on single inland letters were reduced to 3 cts. for all distances under 3,000 miles, and 10 cts. for all over that distance; and all inland letter postage was to be prepaid. The charge for advertising letters was reduced to 1 cent. The only modifications since made in the law are those of 1860, establishing letter boxes on lamp posts, &c., in cities, requiring all letters deposited in them to be prepaid with a penny stamp to defray the cost of their carriage to the post office, and reducing the carriers' fee for the delivery of letters at their address to 1 cent per letter. Various attempts have been made to abolish the franking privilege, but hitherto without success. The right to frank letters and documents of any size is now granted to the president, ex-presidents, the vice-president, former vice-presidents, and the widows of Presidents Harrison and Polk. Members of congress and delegates from territories, from 30 days before the commencement of each congress until the first Monday in December after the expiration of their term of office, and the secretary of the senate and the clerk of the house of representatives during their official terms, can send or receive free letters weighing not over 2 oz., or public documents weighing not over 3 lbs. The governor of any state can send free the laws, records, and documents of the legislature to the governors of other states. The cabinet officers and their assistant secretaries, the commissioners of offices and heads of bureaus, the general-in-chief and adjutant-general, and the superintendent of the coast survey and his assistant, may send and receive free all official correspondence, but not their private letters or papers. The chief clerks in the departments may send free public official letters and documents. Deputy postmasters can send free all letters and packages relating exclusively to the business of their respective offices; and those whose compensation did not exceed $200 for the year ending June 30, 1846, may also send free all letters written by themselves, and receive free all letters addressed to them, not weighing over ½ oz. Exchange newspapers, magazines, &c., between editors, pass free. All publications entered for copyright, and which under the act of 1846 are to be deposited in the library of congress, pass free. Since the close of the war with Mexico and the annexation of California, the transportation of the mail to the Pacific coast has greatly increased the expenditure of the department, large subsidies having been paid during a portion of the time to the lines of steamships connecting with that coast, and of late very heavy sums for an overland mail. The importance of our relations to the Pacific states fully justifies these expenditures, though the amount of postage received does not defray them.—Postal treaties have been concluded with most of the countries of Europe, and through them letters can be forwarded to nearly every part of the world. The maximum postage of a letter weighing ½ oz. to any known port is 50 cts., and this only to Australia and New Zealand; the usual rates range from 15 to 30 cts., to which is to be added inland postage unless the letter is sent direct from a seaport. Letters not prepaid (except drop letters, where prepayment is optional) and letters advertised, but not called for, are forwarded after a sufficient time has elapsed to the dead-letter office of the post office department and there opened, and if containing any money or valuables the writers of the letters are notified, and the amount forwarded to them on application. Letters on which the address of the writer is written are returned unopened from the dead-letter office. The annual number of dead-letters is about 2,500,000; of this number 500,000 are drop letters, and 50,000 are held for postage; about 134,000 are from foreign countries, and are returned unopened. By the act of March 3, 1855, the postmaster-general was authorized to establish a plan for the registration of valuable letters, on the application of parties desiring it, and the payment of a registration fee of 5 cts.; but the government will not, like that of France, be responsible for the safe carriage of such letters or packets. The whole amount of postage received for registered letters in 1859 was $25,053. Only the states of Massachusetts, Rhode Island, and New York, and the District of Columbia, receive a larger amount of postage than is expended for the transportation of the mails and the compensation of those employed in the postal service.—The accompanying table gives a view of the comparative expenses, receipts, expenditures, and other statistics of the post office service in Great Britain, France, and the United States:

Particulars.	Great Britain.	France.	United States.	
	1859.	1859.	1859.	1860.
Population	28,883,597	36,746,482	31,279,885	31,279,885
No. of post offices	....	8,703	28,539	28,498
No. of persons employed in postal service	25,000	28,000	30,636	30,529
No. of letters transmitted	545,000,000	259,450,000	....	....

POST, **Wright**, an American physician and surgeon, born in North Hempstead, Long island, Feb. 19, 1766, died at Throgg's Neck, June 14, 1828. He was a medical pupil of Dr. Bayley of New York for 4 years, and then went to London, where from 1784 to 1786 he studied under Dr. Seldon. Returning to America, he delivered a course of lectures on anatomy in Columbia college, and in 1792 was made professor of surgery in that institution.

He went to Europe immediately after the appointment, and visited all the great medical schools, and on his return in 1798 resigned the professorship of surgery and became professor of anatomy and physiology. This office he held 20 years, during which time he became widely known by his skill in performing many delicate and difficult operations. In 1813 he was made professor of anatomy and physiology in the college of physicians and surgeons in New York, and in 1815 made another visit to Europe. In 1821 he was elected president of the college of physicians and surgeons, which office he held 5 years.

POTASH, or POTASSA, a term variously applied to several compounds formed by the metallic base potassium, and other elements. In chemistry it is used to designate the protoxide (KO), consisting of one equivalent each of this base and of oxygen, and this is the ingredient in the compounds, hydrate, carbonate, nitrate, sulphate, &c., of potash, combinations respectively of this substance with water, carbonic acid, nitric acid, and sulphuric acid. The hydrate of potash ($KO\,HO$), also known as caustic potash, is sometimes called simply potash, as are in the arts and commerce the crude carbonate and hydrate from which most of the other compounds are prepared.—Potash, the protoxide of potassium, is of itself of little interest or importance. It is obtained as a white powder when the metal potassium is exposed in thin slices to dry air. At a red heat it fuses, and at higher temperatures is volatilized. In contact with water it ignites and forms a fusible hydrate, which is also known as caustic potash. This compound is of great importance in the arts, chemistry, and pharmacy, not only as the base of numerous useful salts, but for its own independent properties. It is commonly prepared from the carbonate, a solution of which in 10 to 12 parts of water is boiled with about an equal quantity of freshly slaked lime, made in a paste with water, and gradually added to the solution. The boiling is performed in a clean iron vessel, and is continued for about half an hour. The lime seizes the carbonic acid of the carbonate of potash, and leaves the hydrate of potash in solution; and the operation is found to be complete when no effervescence is observed on taking out a portion of the liquid and adding a little hydrochloric acid. It may then be drawn off in part from the calcareous sediment, and the remaining portion be recovered by filtering through a cotton filter, protected as much as possible from the air, by which it might again be partially carbonized. The clear solution is now evaporated rapidly in a polished iron or silver vessel, till it becomes of an oily consistence and hardens on cooling. Before it is allowed to cool it is usually run into cylindrical moulds, and thus is formed in sticks, which are the caustic potash or *potassa fusa* of the pharmacopœia. It contains impurities, as sulphate and carbonate of potash, chloride and peroxide of potassium, oxide of iron, and alumina, from most of which it may be freed by dissolving in absolute alcohol, evaporating, and again fusing. Hydrate of potash may be economically separated from some feldspars and micas by calcining the minerals with lime and leaving the products for some time in contact with water. According to Fuchs, 19 per cent. of potash may thus be obtained from feldspar, and 15 per cent. from mica. The pure hydrate is a white solid substance, of crystalline fracture, and specific gravity 1.7. It is very deliquescent, dissolving readily in water, the solution of specific gravity 1.68 containing 51.2 per cent. of the alkali and boiling at 329° F. It fuses at a low red heat, and at a white heat it volatilizes without separation of the water. It has an acrid taste and corrosive action upon the cuticle, dissolving and decomposing organic tissues. It is the most powerful base known, and is hence largely employed for decomposing saline compounds, the acids of which it seizes. It absorbs carbonic acid from the atmosphere, and must consequently be preserved in glass-stoppered bottles, and the glass of these must be free from lead. Mixed with the fat oils it forms soaps; and in various other ways it is a most useful article in the arts, in chemistry, and to some extent in medicine. The pharmaceutical preparation known as *liquor potassæ* is a solution in water of the hydrate of specific gravity about 1.05, and containing 4.7 per cent. of potassa. Its properties as an antacid, &c., are however as conveniently serviceable in the carbonate of potash. In excessive doses its poisonous action is neutralized by vinegar, the milder acids, or the oils.—Commercial potash, the crude carbonate and hydrate, is wholly obtained from wood ashes, and is the chief portion of the soluble matters which these contain, except when made from plants that grow near the salt water. In these the potash is more or less completely replaced by soda, so that they are used to produce this alkali in the same manner that other plants afford potash. The alkalies that exist in the soil are derived from the decomposition of different rocks and minerals. Feldspar and mica, ingredients of granite, are particularly prolific sources of potash and soda. They cannot, however, be made to yield these alkalies so economically as the plants, which have taken them up in their sap and hold them in a soluble state, combined with oxalic and tartaric and other vegetable acids, and also with silicic and sulphuric acids. By burning the plants, the salts of the vegetable acids are decomposed, and the potash combines with carbonic acid, remaining with the ashes as a carbonate. The ashes, moreover, contain as soluble ingredients carbonate of soda, the sulphates and silicates of potash and soda, and chlorides of the metals, including chloride of potassium; and beside these, insoluble earthy matters, which are of no value in connection with the production of the alkalies. The proportion of these two classes of ingredients varies in ashes obtained from different plants and their parts, ranging generally from $\frac{9}{10}$ to $\frac{4}{5}$ insoluble, and consequently leaving $\frac{1}{10}$ to $\frac{1}{5}$ soluble. Berthier found the soluble portion of the ashes of oak wood to amount to 12 per cent., of white beech wood 19.22, red beech 16.8, birch wood 16, fir wood 25.7, fir charcoal 50, pine wood 13.6, wheat straw 10, and potato vines 4.2; and other chemists report the ashes of bean vines to contain 33 per cent. of soluble matter, of pea vines 27.8, of rye straw 19.47, &c. The branches and bark contain more saline matters than the solid wood, a distribution perhaps dependent on the potash existing chiefly in the sap. Tables presenting these values are contained in the treatise on this subject in the first volume of Dr. Knapp's "Chemical Technology," translated by Drs. Ronalds and Richardson. A table is also found there giving the proportions of ash found by different chemists in various plants and in their different portions. See also a table of M. Violette in the article FUEL, vol. vii. p. 780, representing among other ingredients the quantity of ash in different parts of the cherry tree. The whole amount of ashes from the solid wood of trees generally falls short of 1 per cent. of the whole weight, but sometimes exceeds this 2 or 3 times. The bark often produces 6 per cent. of ashes; and vines, straw, &c., still larger proportions. Thus potato vines have given 15 per cent.; pea vines to different experimenters 5, 8, and 11 per cent. respectively; wheat straw 4 to 7 per cent.; corn stalks 12 per cent., &c. The proportions of potash actually separated from different plants are given as follows by Vauquelin, Pertuis, Kirwan, and De Saussure:

	Per ct. of potash.		Per ct. of potash.
Pine or fir	0.045	Large rush	0.725
Poplar	0.075	Corn stalks	1.750
Beech wood	0.145	Bean stalks	2.000
Oak	0.153	Bastard chamomile, anthemis cotula, L.	1.960
Box wood	0.226	Sunflower stalks	2.000
Willow	0.285	Common nettle	2.500
Elm and maple	0.390	Vetch plant	2.750
Wheat straw	0.390	Thistles in full growth	3.500
Bark of oak twigs	0.424	Dry wheat straw before earing	4.700
Thistles and flax stems	0.500	Wormwood	7.300
Small rushes	0.508	Fumitory	7.900
Vine shoots	0.550	Angelica	9.620
Barley straw	0.580		
Dry beech bark	0.600		
Fern	0.626		

The stalks of tobacco, potatoes, beet leaves, tansy, sorrel, &c., contain large proportions of potash, and the removal of such products every year from the soil must cause its impoverishment, unless the potash is restored in other ways.—When ashes are treated with water a strongly alkaline solution is produced called a lye, and when this is drawn off and evaporated to dryness the soluble salts remain behind. The evaporation used to be conducted in iron pots, and hence the name potash. The manufacture is largely carried on in several wooded countries, especially where it is desirable to clear off the forests for agricultural purposes; but it appears to be northern countries alone that produce supplies for commerce. These are the northern American states and Canada, and Germany, Russia, and the other countries of the north of Europe. Various other vegetable productions beside forest trees are consumed for producing potash, and, as will be seen from the above table, some of them, as the herbaceous plants especially, afford a much larger proportion of ash than the solid wood of trees. Straw, among articles that are readily procured in large quantities, is particularly productive, and in Russia it is burned together with weeds for potash. In France the lees of wine and other refuse of the distilleries and vineyards furnish an abundant source of potash; and in Java it is obtained from the stems and leaves of the indigo plant after the coloring matter has been extracted. The method pursued in the American forests is to burn the wood in large heaps to ashes. Barrels sawed across in the middle furnish tubs, which are provided with a false bottom perforated with holes and supported upon cross sticks a little above the real bottom. Straw is laid upon the false bottom, under which is a cock for letting off the lye. The ashes mixed with about $\frac{1}{5}$ of lime are now placed in the tubs and drenched with successive portions of water, which are allowed to remain for an hour or two. Those first drawn off, being saturated with the soluble salts, are conveyed directly to the evaporating pans; but the succeeding portions, being weak, are retained to use again upon fresh ashes. The pans are of iron, broad and shallow, and with corrugated bottoms to increase the heated surface. When the liquor becomes of sirupy consistence the heat is checked, and the contents of the pan soon solidify. These when cold are dug out with some difficulty and placed aside as crude potashes. They are intensely alkaline, and of a reddish brown color from the carbonaceous matter they retain. They are afterward purified by heat on the floor of a furnace, losing most of the sulphur that may be present, the excess of water, and other volatile matters, the whole loss amounting to 10 or 15 per cent. The product is white, of a bluish or pearly cast, contains a larger proportion of carbonic acid than the crude article, and is known as pearlash. The effect of the lime added to the ashes is to decompose the sulphate of potash found among the salts of the ashes and recover the potash, while the sulphuric acid is rendered insoluble by combination with the lime, and is retained with this portion of the ashes. Crude potash and pearlash are both somewhat variable in composition. The former contains a large portion of caustic or hydrate of potash, and its percentage of absolute potassa often amounts to 60. In the latter the potash is in the condition of a carbonate, representing a percentage of about 50 of absolute potassa. The commercial value of the article is determined by the amount of acid required to neutralize the alkaline reaction of a known weight of the salt, as described in the article Alkalimetry. Graduated instruments, called alkalimeters, are in use for facilitating this operation, and various modifications of the process are given in the chemical works. Pearlash is purified by dissolving it in one and a half times its weight of water, applying a gentle heat, and then drawing off the solution from the salts that settle in the bottom. The liquid is rapidly evaporated by heat, and as it is allowed to cool and begins to crystallize it is kept in agitation so that only small crystals of nearly pure carbonate of potash may form. The solution obtained by treating the bitartrate of potash (cream of tartar) with water filtered and evaporated, affords still purer crystals of carbonate. Crystallized carbonate of potash contains two equivalents of water, and is represented by the formula KO CO_2, 2HO. The dry anhydrous salt is very deliquescent, attracting water till it becomes liquid; it fuses at a red heat, and dissolves in less than its weight of water. It is not soluble in absolute alcohol. It consists of one equivalent of carbonic acid, 22, and one of potassa, 47.2 = 69.2. In the chemical arts carbonate of potash is largely employed to neutralize acids, also as a flux, and to form the other salts of potash. In medicine purified pearlash, often called salt of tartar, is variously employed—sometimes as an antacid, also as a diuretic and antilithic. For cutaneous eruptions it is one of the most effectual remedies, and is employed both internally and externally. The pure carbonate, prepared from cream of tartar, and formerly known only as salt of tartar, is to be preferred to purified pearlash for the preparation of citrate of potassa, known as the neutral mixture or effervescing draught, an excellent refrigerant diaphoretic, very generally administered in remittent and other fevers. —Various other salts of potash are extensively employed in the arts and also in medicine. Among the most important of these are the nitrate, saltpetre (see Nitre), the chromates (see Chromium), the bitartrate (see Cream of Tartar), the hydriodate and prussiate (see Potassium), the chlorate (see Chlorates), and sulphate. Sulphate of potash (KO, SO_3) is obtained in anhydrous crystals of the form of 6-sided prisms terminating in 6-sided pyramids, or in oblique 4-sided prisms, by neutralizing with carbonate of potash the bisulphate of potash that remains in the manufacture of nitric acid from nitre. The crystals are unalterable in air, and the salt is one of the least soluble of the neutral salts of potash, requiring about 10 parts of cold or 4 parts of boiling water to dissolve it. In alcohol it is insoluble. Its use is in medicine, its properties being those of a mild purgative. The hydrated bisulphate (KO, SO_3+HO, SO_3), the residue in the preparation of nitric acid from nitre, the *sal enixum* of the alchemists, is obtained in a white crystalline mass. It crystallizes from a strongly acid solution in rhomboidal tables. The salt dissolves readily in water, but is in part decomposed by it, and a portion of sulphate of potash is deposited. The use of the bisulphate is as a flux in chemical operations requiring the action of an acid at high temperatures on salts or metallic oxides with which it may be fused.

POTASSIUM, the metallic base of potash, symbol K (*kalium*), chemical equivalent 39. That the alkalies and earths were of compound nature had been for some time suspected before Sir Humphry Davy, in 1807, demonstrated the fact in regard to this alkali, a discovery which was soon followed by the resolution of the other compounds referred to into their constituents of oxygen and a metal, and the important modifications in chemical science involved in these great discoveries. He effected the decomposition by employing the hydrate of potash, moistened on its surface by exposure to the air for a short time, and subjecting this to the action of a galvanic battery of 200 pairs of 4-inch plates. Previous attempts to decompose the potash in solution in water had failed on account of the voltaic current acting upon the fluid rather than the alkali; the dry hydrate, being an insulator, was not affected by the current. Globules of potassium appeared at the negative pole, and bubbles of oxygen at the positive. The metal thus obtained was very small in quantity, and on account of its great affinity for oxygen it was found necessary to protect it from both air and water, either in mercury, with which it formed an amalgam, or in naphtha. The next year Gay-Lussac and Thénard succeeded in decomposing melted hydrate of potash by causing it to pass through a gun barrel, which contained iron filings and was kept at a white heat. The oxygen of the potash and of the water it contained was taken up by the iron, and the potassium set free passed through and was condensed in a cool receiver of copper. The method now employed to produce potassium is that invented by M. Curaudau and improved by M. Brunner, and particularly described in the *Annales de chimie* (iii.), xxxv. p. 144. The reducing agent in this process is charcoal, and to obtain it in the most efficient form and most intimately mixed with the potash, cream of tartar (bitartrate of potash) is employed and ignited in a closely covered iron crucible, till it ceases to emit combustible vapors. The operation is facilitated by the intermixture of about 10 per cent. of coarsely pulverized charcoal, which keeps the mass open and permits the gases to escape. As the vegetable acid decomposes, its carbon is left intimately mixed with the resulting carbonate of potash, giving the product a black color. The crucible is cooled rapidly by cold water applied to the outside, and the contents broken into small pieces are introduced into an iron bottle, as a quicksilver flask, which is provided with a discharge tube, also of iron, and placed horizontally in a furnace. The discharge tube is of good capacity, and is made of the least possible length to enter the receivr, which is placed close up to the iron plate of the furnace. These precautions are necessary on account of the danger of the tube becoming obstructed by the accumulation of potassium. When the retort is raised to a red heat, it is sprinkled over with vitrified borax, which melts and protects the iron from oxidation. The fire is then urged to obtain a most intense heat, and after a time greenish vapors of potassium appear at the end of the tube, bursting as they mix with the air into a brilliant flame. The receiver already prepared is now adjusted to the tube. It is constructed in such a manner as to be kept cool, while the tube from the bottle is red-hot, and at the same time to exclude the air from without. In one form it consists of two cylindrical vessels of sheet copper, the upper one set with its open end down into the lower one, to which it serves as a cover. The connecting tube enters it near the top through a closely fitting socket of copper, and by the interposition of a partition or diaphragm, which divides the upper receiver into two parts, all the products of the distillation are forced to descend within two inches of the bottom, where some rectified petroleum catches the potassium as it falls drop by drop from the end of the tube. Carbonic acid also comes over, and passing under the diaphragm escapes through a glass tube inserted for the purpose near the top of the receiver. To prevent the connecting tube from becoming clogged with potassium, an opening is made directly opposite to it on the other side of the receiver, and also through the diaphragm between, by which an iron wire can be used to remove the obstructions. The receiver is kept cool by means of ice placed in a wire cage that is set over the upper portion; and the lower part may also be set in ice. Another form of receiver is that of an iron box a foot long, 5 inches wide, and only ¼ inch deep. It is made of two pieces of wrought iron, the pan below and its cover, which are clamped tightly together. One end has a short neck with an aperture large enough to receive the connecting tube, and the other is open the whole width of the box. The apparatus is kept cool by a wet cloth placed upon it. The potassium condenses immediately in the box, and the carbonic acid gas passes out at the open end. Through this end an iron rod is introduced when necessary to remove any obstructions in the tube; but if this should become closed the fire must be immediately withdrawn by removing the bars that support it. As soon as the gases cease to flow the receiver is removed and instantly plunged into a vessel of naphtha, which is then covered tight and immersed in water. When cold, the potassium is detached from the receiver and preserved in naphtha. It is not safe to keep it except it be purified by a second distillation; but before the connecting tube is used again it should be washed in water to remove the impure potassium that collects in it. A smaller iron bottle may be used the second time with a bent tube terminating in naphtha contained in a capacious flask. It may also be purified by squeezing it under naphtha through a piece of linen with wooden pliers. Potassium is a silver-white metal, at ordinary temperatures soft like wax, toward the freezing point malleable, and at this point brittle and sometimes crystallized in cubes. At 70° it is semi-fluid, and at 150° it is liquid. Its density at 60° being only 0.865, it floats upon water; and thus placed its strong affinity for oxygen is remarkably exhibited. The water is decomposed, and great heat is evolved, so that the potassium takes fire, and the hydrogen of the decomposed water also burns with it. The metal darts rapidly about upon the surface, accompanied by a brilliant flame, till at last, cooling down sufficiently to come in contact with the water, it disappears with an explosive burst of steam. Exposed to the air, potassium soon becomes covered with a film of the protoxide, and when heated till it begins to form vapor it takes fire and burns with a violet flame. The product of this combustion is the peroxide, KO_3.—The most important salts of potassium are the iodide, also known as hydriodate of potash, and the combinations of the metal with cyanogen. Iodide of potassium (KI), much used as a medicine, is prepared by several methods which are given in the pharmacopœias. One of these is to dissolve iodine in a strong solution of potash, whence results iodide of potassium and iodate of potash in colorless solution. When so much iodine is taken up as to give its color to the liquid, this is evaporated to dryness and cautiously brought to a red heat. The iodate is thus converted into the iodide, which fuses, and if too strongly heated volatilizes. It is next dissolved in water, filtered, and crystallized. It takes the form of cubes or rectangular prisms, which are generally white and opaque, and have an alkaline reaction from a trace of carbonate of potash. The salt, commanding a high price, is often adulterated. If pure, it should not effervesce nor turn brown on addition of hydrochloric acid, the former effect indicating the presence of carbonate of potash, and the latter of iodate of potash. It should dissolve completely in 6 times its weight of alcohol. The chlorides of potassium and sodium and the bromide of potassium are also often found in this salt, and the last named is sometimes fraudulently substituted for it. The presence of a chloride is detected by nitrate of silver producing a precipitate that is readily soluble in ammonia. Bromide of potassium may be distinguished from the iodide by its giving no precipitate with bichloride of mercury. This salt is variously employed in medicine, and its effects upon the secretions, when administered as an alterative, are very marked. It may be regarded as an antidote to the poisonous effects of lead and mercury which remain fixed in the tissues. These, being converted by it into iodides, are rendered soluble and pass off. When exhibited in connection with certain compounds of mercury, it has been observed to increase the activity of these medicines in a remarkable degree, probably by making them soluble. As an antidote to the poison from the bites of venomous reptiles, its properties have been alluded to in the article POISON. The salt passes quickly into the urine, in which it has been detected in 6 minutes after swallowing. It is employed externally as an ointment, either alone or mixed with iodine.—The compounds of cyanogen and potassium present 3 or 4 very important salts: the ferrocyanide, also known as yellow prussiate of potash, the sesquiferrocyanide or Prussian blue, the ferridcyanide or red prussiate of potash, and the cyanide of potassium. The first named, from which the others and all the other compounds of cyanogen are derived, is manufactured upon a large scale by calcining at a high temperature nitrogenous animal matters, as dried blood, hoofs, horns, parings of hides, woollen rags, refuse of tallow chandlers, and other such substances, with an equal weight of carbonate of potash and about $\frac{1}{8}$ their weight of iron filings, in a covered iron pot; or the filings may be in part or wholly omitted, in which case the pot itself and the stirrers used furnish the required amount of iron. A dark gray mass is obtained, which being treated with hot water yields what was formerly known as the *lixivium sanguinis* or blood lye. This being evaporated produces impure lemon-colored crystals of prussiate of potash. By redissolving and crystallizing by long continued evaporation, they are obtained again perfectly pure in large tabular forms, transparent, and of composition represented by the formula K_2, $Fe\ Cy_3 + 3HO$. The salt is very soluble in water, but is insoluble in alcohol; it has a saline bitterish taste, and has not the poisonous properties of some of the cyanogen compounds. It is tough and not readily reducible to powder. Heated to 212° F., it loses its water of crystallization, amounting to 12.6 per cent. of its weight, and crumbles to a white powder. At a red heat in close vessels it fuses, and finally decomposes in part, nitrogen escaping and cyanide of potassium and carburet of iron being formed. By the admission of air the cyanide is converted into cyanate of potash. The uses of this salt are numerous and very important. In dyeing and calico printing it is the source of some of the colors employed, especially the blues. In chemistry it is a reagent in the wet way for distinguishing metals in solution from each other. The precipitates it occasions in acid metallic solutions are generally combinations of the cyanide of the metal thrown down with cyanide of iron, and the metal is recognized by the peculiar color of the precipitate; thus with salts of copper the precipitate is reddish brown, with salts of cobalt yellowish green, with protosalts of iron white changing to blue, with persalts of iron a deep blue, &c. Thus are obtained some of the colors used in dyeing. In metallurgy this salt is used as a flux, and also in the manufacture of steel from wrought iron, to which when melted together it imparts the carbon necessary for the conversion. It has also recently come into general use for increasing the hardness of steel upon the face of which it is melted. In pharmacy it is used to prepare diluted hydrocyanic acid, Prussian blue, and the cyanides of potassium and silver. In medicine it is found to possess the properties of a sedative, diaphoretic, and astringent, but is little used.—The sesquiferrocyanide of potassium, or Prussian blue, is a pigment of great value discovered in 1710 by Diesbach, a color maker at Berlin, and the first account of its manufacture appeared in 1724 in the "Philosophical Transactions." The salt is the precipitate obtained by mixing a solution of a persalt of iron with one of ferrocyanide of potassium, and its composition is represented by the formula Fe_4, Fcy_3. The iron salt usually employed in its preparation is the green vitriol, sulphate of the protoxide, which before mixing with the potash solution is converted into peroxide. It is used on account of its cheapness, but the nitrate is much better adapted for producing the finest sorts of Prussian blue; for the sulphate is rarely deprived altogether of the protoxide salt, and any portion of this remaining produces a blue of inferior quality. Such is the basic or soluble Prussian blue, distinguished from the genuine blue by its character of solubility in water. The character of the products is also materially affected by that of the ferrocyanide of potassium employed. The best, such as the Paris blues, are made with this salt purified by successive crystallizations, while the more common sorts are made from the crude solution before crystallizing, and the inferior sorts even from the mother liquors from which the salt has been crystallized and separated. As all ferrocyanide of potassium except the purest contains some carbonate of potash, this must be neutralized, and for this purpose sulphuric acid is added either to the iron or potash solution. But in making the common Berlin blues a solution of alum is employed; this involves a precipitate of alumina, which becomes mixed with the color, and adds essentially to its weight. Sometimes chalk, plaster of Paris, and starch are purposely introduced as adulterants. The method of manufacture recommended by Liebig is to divide a solution of 11 parts of green vitriol into two portions, and mix one of these with two parts of hydrochloric acid, gradually adding to the mixture chloride of lime until the whole of the protoxide is converted into peroxide. Then the two portions are to be mixed together, and a solution of 10 parts of ferrocyanide of potassium added. The blue precipitate thus obtained is not, however, perfectly pure. Various other processes for making this color are in use. Prussian blue is usually prepared for sale by drying the precipitate in cubical or irregular shaped masses;

but as these are not afterward readily reduced to the fine state of division of the precipitate, this is sometimes sold to the manufacturers of paper hangings in the form of a paste. The dried color breaks with a dull fracture, but when rubbed presents a beautiful reddish metallic lustre like bronze, and altogether bears much resemblance to indigo. It has neither taste nor smell, and is not soluble in water nor weak acids; but washed with dilute hydrochloric acid and then rubbed with ⅛ its weight of crystallized oxalic acid, it is rendered soluble. A fine blue writing ink is prepared by dissolving this mixture in 40 or 50 parts of water. Prussian blue is decomposed by the alkalies and their carbonates, oxide of iron being liberated and a ferrocyanide of the metal remaining in solution. The addition of potash thus reproduces the yellow prussiate, and is an excellent method of preparing this salt in a state of purity. Prussian blue when heated in the open air takes fire and burns like tinder. Its use in the arts is as a pigment. It makes a beautiful water color, which however is not very permanent. It is also of value in dyeing and calico printing. Starch is colored by it, and it forms the "blueing" for coloring linen. In medicine it is sometimes used for its properties as a tonic, febrifuge, and alterative, and also externally as an application to ulcers, mixed with some simple ointment.—The ferricyanide of potassium, or red prussiate of potash (K_3 Fe_2 Cy_6), is also a valuable salt, both as a reagent in chemical analysis and in calico printing. It is obtained in splendid ruby red crystals on evaporating a dilute solution of ferrocyanide of potassium through which a current of chlorine has been passed just to the point when the liquid ceases to give a blue precipitate with the persalts of iron. As it is prepared on a large scale for the calico printer, it is generally obtained by decomposing the solid yellow salt by means of chlorine. The red crystals left from the solution are anhydrous; they are soluble in less than 4 parts of cold water, and in still less hot water. The solution of the salt is used as a test for various metals, producing in their solutions differently colored precipitates. Thus the protosalts of iron are recognized by the beautiful Prussian blue color, the salts of nickel and of copper by yellowish green, of cobalt dark reddish brown, cadmium yellow, zinc and silver orange, manganese bronze, &c.—Cyanide of potassium (K Cy) is a salt largely prepared for various uses in the arts. In electro-gilding it is added to the solution of gold to give it clearness and prevent the deposition of a black deposit; in photography it is used to fix the image upon the plates; in metallurgy it is a powerful reducing flux for the oxides of the metals; and in pharmacy and medicine it is a substitute for hydrocyanic or prussic acid, having the same poisonous qualities. (See HYDROCYANIC ACID.) It is prepared from a mixture of 8 parts of carefully dried and pulverized ferrocyanide of potassium and 3 parts of carbonate of potash, to which may be added one part of charcoal, brought to a red heat in a close iron crucible. When the yellow color disappears and no more bubbles of gas are seen, the fused cyanide is poured off from the ferruginous residue. If no charcoal is added the product is milk-white, and contains cyanate mixed with the cyanide; but if charcoal is used to reduce to cyanide the cyanate that forms, the fused salt when poured out is black and must be freed from the particles of unconsumed charcoal that color it. This is done by treatment with boiling alcohol, and filtering; the salt separates by crystallizing when cold. This treatment is unnecessary if the salt is designed for forming and dissolving the cyanides of gold and silver, or for electro-metallurgical purposes. The crystals of cyanide of potassium are colorless cubes, which become opaque and deliquesce in damp air, and are very soluble in water. The solution has the odor of hydrocyanic acid. Preserved in a tight bottle, the dry salt may be kept for a long time without losing its properties, and for this reason it is to be preferred to the acid poison. As it is sold, it is, however, of very uncertain purity, commonly containing water, the hydrate, carbonate, cyanate, and formiate of potash. The carbonate is the chief impurity, and altogether sometimes makes half the weight of the salt.

POTATO, an esculent tuber produced by the *solanum tuberosum* of Bauhin and Linnæus. The genus *solanum* is the type of the natural order *solanaceæ*, composed of exogens with 5 free stamens, a monosepalous hypogynous corolla divided at top into 5 lobes, and a 5-parted calyx, persistent, inferior; the æstivation plaited, imbricated, or valvate; the fruit either a capsule or a berry; the leaves alternate, undivided, or lobed. They are natives of most of the warmer portions of the world, especially the tropics. Many genera beside the typical one belong to this order, several of which consist of poisonous plants, and others are of importance in medicine. The genus *solanum* contains plants of the herbaceous, shrubby, and tuberous-rooted esculent kinds, of which may be mentioned the tomato, egg plant, bittersweet, winter cherry, the nightshades, and the potato. There are two principal variations of this last, as shown in the color of its tubers, viz., those in which they are red, blue, or purple, and those in which the white or yellow is the prevalent tint; and the sub-varieties under these colors are exceedingly numerous. When raised from seeds, no permanency in form, color, general characteristics, or qualities can be anticipated. A good variety having once originated, it can only be secured by propagation in some other way. Instances are on record where, out of 500 seedlings, not one was like the parent, and only 3 of the entire number worth perpetuating. In order to procure the seeds for sowing, the berry-like fruit, or potato ball as it is termed, should be gathered when it is perfectly ripe and dried, and the seeds rubbed out with the hand. They should be kept in some dry place until the next spring, and then sown in shallow boxes in a good pulverized soil. When 4 or 5 inches high, the young plants should be carefully transplanted into properly prepared beds, allowing 6 inches space for each plant, and keeping the beds clear of weeds. At the end of the season small tubers will be found on the roots of every plant, which must be stored through the winter and planted out the next spring. At the end of the second year some idea of their value can be obtained. By such experiments a few superior sorts can be produced, and these perpetuated by the usual modes of planting.—Different modes of raising potatoes prevail in different parts of the world. In Europe the tubers are carefully cut into small bits, each having an "eye" or stem bud. In Ireland it is not unusual to cut these early in winter and save them until the period for planting; by this means the cut part has time to dry and harden on its surface, and is not so liable to rot if planted in moist soil. These fragments are called "sets," a term also applied to the entire tuber used in planting. All the kinds of potato will grow in almost any soil, but prefer a moderately light and dry one and an open situation. There are various modes of planting. In the dibbling method, small holes 4 or 5 inches deep and 12 inches apart are made by a blunt-pointed tool, and a simple cutting or set being dropped into the hole, the surface of the ground is smoothly raked over. The drill method is by the use of a hoe, the drills being 4 or 5 inches deep and 2 feet apart; into these the sets are dropped at proper distances and covered with about 4 inches of earth. The spade is used in furrow planting. In light ground a system of trenching to a spade's depth is practised; and in very wet lands the soil is thrown up into high broad beds with deep alleys between, the sets being dropped upon some littery manure and covered with earth taken from the alleys. In harvesting, the potatoes are lifted out by a blunt-pointed 3-pronged fork, the haulms or dead tops being burned upon the ground or removed for litter or for covering used in garden purposes. The potato is sometimes forced by selecting dwarf kinds and planting in a hot-bed very early in the year. For early crops, drills 2 feet apart and 7 or 8 inches deep should be formed in some warm and sheltered situation. Half decomposed stable dung is laid in the drills and mixed with the soil, and a covering of mould laid to within 4 inches of the surface. The sets should be uncut, the upper or crown end of the tuber uppermost, and placed in the drill, with about an inch of mould strewn over them, and occasionally a sifting of wood ashes. The sides of the drills are lined with dry leaves to guard against frosts.—The process in the United States is less diversified, the potato being more generally regarded as a field crop. It is considered advisable to plough the land deep and to break it up with the hoe. When greensward is used just before planting time, the latter precaution is not so necessary. Manures that will lie lightly are found advantageous, and next to these, kinds that ferment slowly. Next in value to a new soil is the use of old salt hay or oak leaves, and similar vegetable matter always at hand. New lands recently burned over also produce excellent potatoes. As a crop the value in a commercial view depends less on the quantity raised than on the quality of the tubers. The higher the land is manured, the greater the quantity, but not always the better the quality. In the northern and eastern states the time of planting may be from May 1 to the end of June; but sufficient time should be allowed for the foliage and stems to come to maturity and ripen, otherwise the tubers will not be well grown. In preparing the sets or seed potatoes, as they are often called, some advise cutting into small pieces, and others planting entire and large tubers. Where the ground is rough and stony, the older method of planting in hills may be as good as any; but in rich and mellow soil the drill method is preferable. This can be done in an expeditious way by cutting furrows with a horse plough, dropping the sets, and covering them by passing the plough along the back of each furrow, and levelling afterward. When the crop is ready for hoeing, the cultivator may be employed between each furrow, weeding the plants and keeping the soil loose and mellow around them, avoiding too much hilling up. On harvesting the crop, exposure to the sun's rays should be avoided; it should be housed as soon as convenient in cellars or caves dug in a dry soil, and protected from frost and light. Toward spring the sprouts are to be removed and the potatoes kept dry for table use.—The potato differs in shape of the tuber, in foliage, flowers, and prolific qualities. The leaves of some resemble those of the ash tree, and these are called the ash-leaved sorts. The blossoms are white, violet, or pale, and the tubers are in shape globular, kidney-shaped, flat, long cylindrical, tapering, curved, conical or pineapple-shaped, and imbricated; their exterior is smooth, rough, granulated, or warty, and in color white, yellow, pink, purple, blue, or almost black. More than 50 distinct kinds are known, each possessing some particular merit. Of these many are foreign sorts seldom or never seen here, and varieties best suited to each climate or even to particular districts originate and are perpetuated. Some sorts, too, are prolific in flowers and seed balls, while others are nearly or entirely deficient in them; and the stems and leaves of some are ranker, coarser, larger, and of a deeper green than those of others. It has been proved that such as ordinarily seldom produce blossoms can be made to do so by robbing the growing plant of some of its tubers. In the United States many aluable sorts have gone out of general use or een superseded by others. The long red, Chenango, blue nose, state of Maine, Jackson white, strawberry, peach blow, and Davis's seedling are esteemed, and may be cited as examples or specimen sorts.—The potato boiled is considered an excellent food for swine, and the English use it in a parboiled state for cattle; boiled and mixed with meal, it can be fed to fowls. The tubers are extensively used for making starch in domestic economy, and by distillation they produce spirits. The farina or starch of the potato is often fraudulently sold for arrowroot, but the microscope readily detects the imposture. An extract of the leaves is a powerful narcotic, ranking between belladonna and conium, and particularly serviceable in chronic rheumatism and painful affections of the stomach and uterus.—The potato is subject to diseases which seriously affect its value as a crop. In Europe, the foliage sometimes presents the appearance of a rough and uneven surface, supposed to be due to a preternatural inspissated condition of the juices in the firm and mealy tuber used in planting. This injury to the leaves is called the curl, and is attributed by Mr. Andrew Knight to the state of the sap, which could not circulate freely within the growing foliage. He experimented upon some sprouts which he carefully detached from the tubers of diseased and curled plants, and found that on being planted they depended for growth entirely on the soil and its water, instead of drawing nutriment from the tuber; by this means no curl appeared, while more than nine tenths of the plants raised from the same diseased tubers proved very much infected. From this it would appear that tubers used for sets when not quite ripened would be productive of a cleaner and healthier foliage. Such unripe tubers have been found the best to plant for early crops; and when the set is cut, the end of the potato which has been last produced has proved to be preferable. In some particular varieties this distinction between the ripened and unripened end is more apparent. The potato, on account of its remarkable nutritive qualities, has been made a principal article of diet, especially with the laboring classes of Ireland. Partial failures of the potato crop and consequent distress have been frequent in that country. In 1739 a severe and early frost which destroyed the tubers in the ground caused great suffering and famine, and in 1822 the rotting of the potatoes after being stored produced the same effects. In 1831 famine and pestilence succeeded the failure of the crop in the western counties, resulting from an inexplicable phenomenon to which the name of the taint was given; it reappeared in 1838. In the meanwhile the potato disease, under the various names of mildew, murrain, rot, and pestilence, was working its way all over Europe, baffling the inquiries of scientific men and of practical agriculturists alike in seeking its cause or its preventive. It first appeared distinctively in 1845, the potatoes being found rotting late in the autumn of that year; while in 1846 a single week's time was sufficient for it to destroy the entire crop, previously to which an abundant harvest was anticipated. The accounts from all parts of the country gave full proof of an impending universal famine. Relief committees, new means of industry, and liberal assistance from abroad were provided. In the United States similar losses to the agriculturists ensued, and the potato crops were seriously injured. It was soon ascertained, however, that particular varieties were most liable, and selections were accordingly made of those freest from contagion. Raising new sorts from the seed was resorted to, the older kinds being rejected. At present the variety called Jackson white is considered best suited to the market. The disease appears toward the end of August, blackening and killing the foliage and the stems of the most luxuriant crops in a few hours. Fields thus affected are left to as late a period as possible before they are dug, but frequently after storage the work of destruction goes on, until the whole is a mass of putrescence. Putrefaction having once taken place or decay been induced, the various parasitical growths ending in more or less developed fungi are to be naturally expected. Thus results and sequences have been taken for causes. According to the Rev. M. J. Berkley, at least 6 fungi have been charged with this evil, though he considers *botrytis infestans* to be the principal one. Certain it is that the potato when planted on new soils and in poor ground, or when vegetable substances are used for manuring, is usually healthy; while lands manured with the exuviæ from the barn are peculiarly liable to impart the disease. Another disease, known as dry rot, does not entirely destroy the value of the root for feeding to swine, but is equally destructive to the germs, so that no sprouts will appear.—The potato is sometimes liable to the presence of an excess of a poisonous principle known as solanine, existing in several species of *solanum*, but particularly in sprouted potatoes, such as are stored for winter use. A very small quantity of this principle will produce symptoms of poisoning, as has been proved by actual experiment. Sprouted potatoes when about to be used as food prove better if pared and soaked for some hours in cold water; and such a precaution may preclude the possibility of any poisonous result from their use.—The native country of the potato is a matter of doubt, but common report refers it to Peru. The potato now in use is said to have been carried to England by Sir Walter Raleigh from Virginia in 1586. As early as 1597 Gerarde gave a figure of the potato plant in his "Herbal," and 43 years later Parkinson published a figure of it in his "Theatre of Plants," describing with it several kinds of similar roots which were eaten, but which belong to entirely distinct genera. Pedro Cieca in his "Chronicle" (1553) says that the people of Quito eat a tuberous root which they call *papas;* and some of the same were sent from Flanders to Clusius, a distinguished botanist of that day. It seems highly probable that the potato was introduced into Europe by the Spaniards, but though thus known to botanists and others its use as an esculent was very tardily adopted. Doubtless it was a long time before amelioration from climatic influences rendered it of good size, farinaceous, and palatable.

POTATO, Sweet, the tuber of an exogenous plant belonging to the natural order *convolvulaceæ*, and called by Choisy *batatas edulis*. It differs from the convolvulus in having a 4-celled ovary, each cell containing a single seed. The native country of the sweet potato is unknown, but it probably originated in tropical America. It must have been early introduced into Europe, and naturalized in the warmer parts of Asia, where a red-rooted variety of it is extensively cultivated for food. It is also known in Spain, in the south of France, and in Italy. The sweet potato has a creeping stem, rarely twining; its leaves are variable in shape, usually angular; they are also lobed and furnished with a petiole, smooth or even slightly hairy; the flowers are 3 or 4, peduncled; the sepals 5, acuminate, mucronate, rarely subtruncate, outer ones a little shorter; corolla campanulate, of a purple color; stamens 5, enclosed; stigma capitate, 2-lobed. The genus *batatas*, according to Don, comprises 16 distinct species, mostly natives of the tropics and conspicuous for the beauty of their flowers. They require much artificial heat in cultivation, a treatment which is given to the sweet potato in some parts of Europe. Catesby, in his "Natural History of Carolina," speaks of 4 or 5 kinds with different colored roots. He says that they should be kept in winter in caves secure from the frost, a method practised now with those designed for planting; and such are likewise packed in dry sand and kept warm until the end of winter, when they are started in hot-beds, and the sprouts having grown a few inches long are carefully taken off. In this state they are sold at the seed stores under the name of slips; these, being set out, produce new plants and abundance of tubers. They delight in a tolerably rich, light, and sandy soil, no extra care being needed except keeping the plants clear of weeds and drawing the soil up around them as they grow. In the southern United States the cultivation is extensive; in New Jersey and the western states the produce is remarkably good; and even in the neighborhood of Boston, Mass., hundreds of bushels are annually raised on the light sandy soil, the yield per acre being little inferior to that of the common potato. In all hot countries the tubers are largely consumed as food, either boiled or roasted. The *batatas littoralis* of Choisy grows wild in the drifting sands of the sea coast from South Carolina to Florida. Its leaves are 1 to 2 inches long, oval or oblong, cordate, notched at the apex, entire or hastate-lobed, the lateral lobes entire or 2-cleft, the flowers white and large. The *batatas macrorhiza* or *jalapa* (Lindley) has a very large root, and is found in similar situations; it is sometimes eaten by the negroes, being found farinaceous and saccharine.

POTATO FLY. See Cantharides.

POTATO WORM. See Hawk Moth.

POTAWATAMIE, a S. W. co. of Iowa, separated from Nebraska by the Missouri river, and drained by the Boyer and West Fork of Nishnabatona river, beside several large creeks; area, 960 sq. m.; pop. in 1860, 4,962. Its soil, which is diversified by prairie and forest, is generally fertile. The productions in 1859 were 16,561 bushels of wheat, 238,585 of Indian corn, 9,834 of oats, 26,954 of potatoes, 4,306 tons of hay, and 40,463 lbs. of butter. Capital, Kanesville.

POTEMKIN, Grigori Alexandrovitch, prince, a Russian statesman and soldier, born near Smolensk in Sept. 1736, died between Jassy and Nikolaiev, Oct. 15, 1791. He belonged to a noble Polish family in reduced circumstances, entered the Russian army at an early age, and became an ensign in the horse guards. After the revolution of 1762 at St. Petersburg, he was appointed by the empress Catharine II. colonel and gentleman of the bedchamber, and admitted to her private circle. Having served for a while under Romanzoff against the Turks, he was sent from the army to present the empress with the keys of the city of Bender, and was bold enough to make in her presence an avowal of passionate admiration which was not unfavorably received. He superseded Gregory Orloff in the good graces of Catharine, and for years had entire control over the heart and the councils of his imperial mistress. He favored the policy which brought about the first partition of Poland, but turned his attention principally to the East; and under his influence the Russians pushed their conquests toward the Black sea with the ultimate view of reaching Constantinople. As early as 1774, by the treaty of Kootchook-Kainarji, they were possessed of Azov, Yenikale, Kertch, and the banks of the lower Dnieper, while they had destroyed Turkish influence in the Crimea. By Potemkin's advice, the foundations of Cherson were laid in 1778, and the new city soon became the chief emporium of south Russia. In less than 5 years he took possession of the Crimea and the Kooban region, to which their ancient names of Tauris or Taurida and Caucasus were restored; and as a reward for his services, he received from his sovereign the governorship of the new provinces, the surname of Tauridian (Tavridtcheskoi), and the magnificent Taurida palace at St. Petersburg, built expressly for him. He now prevailed upon the czars of Georgia and Imeretia to do homage to the empress. In 1787, having persuaded Catharine to visit his government, he accomplished wonders to impress upon her mind the importance and prosperous condition of her new acquisisions. She came surrounded by the ambassadors of all nations and followed by an army of 40,000 men. Along the road she travelled happy-looking crowds cheered her passage; beautiful villages had sprung up in the wilderness, and the country seemed to be at once populous and wealthy. All these were but scenic exhibitions prepared by the art and lavish expenditure of the governor. The journey was scarcely completed when the war broke out again between the Porte and Russia. The chief command was given to Potemkin, who had several experienced generals under his orders, and Turkey was invaded. At the head of the principal army, he took Otchakov by storm; victory followed upon victory; Bender surrendered; Bessarabia, Moldavia, and Wallachia were occupied, and the strong fortress of Ismail fell. But the Russian treasury was exhausted, and Catharine was willing to make peace with her conquered opponent. Potemkin, who thought himself fairly "on the road to Byzantium," wanted to push on the war more energetically than ever; and in the hope of bringing over the empress to his policy, he repaired to St. Petersburg. But while he was here giving a magnificent entertainment to his mistress and her court in the Taurida palace, secret orders had been despatched to his lieutenant Repnin, who hastened to win a new victory over the Turks, and to grant them an armistice preliminary to the conclusion of peace. On hearing of it, Potemkin in a rage started for the south, overwhelmed his lieutenant with reproaches and insults, and swore that "he would undo all that the other had done." He was now at Jassy, where plenipotentiaries had met to negotiate. For some unknown reason he left that city for Nikolaiev while suffering under an epidemic distemper; on the journey he was seized with a violent colic, alighted from his carriage, threw himself on the grass by the roadside, and in a few minutes expired in the arms of his niece, the princess Branicka.—This remarkable man owed the commencement of his fortune to his figure and features, but afterward vindicated his claims to it by enterprises that redounded to the profit and honor of Russia. Notwithstanding his faults, his pride, avarice, intemperance, and coarseness, he was evidently gifted with a powerful intellect, or he could not so long have influenced his benefactress. She loaded him with favors of every kind; he was field marshal, commander-in-chief, and inspector-general of all the Russian forces, president of the college of war, colonel of the Preobrashenski guards, and of 3 other regiments of cuirassiers, grenadiers, and dragoons, grand admiral of the Black and Caspian seas, and governor-general of the provinces of Ekaterinoslav and Taurida. Catharine moreover bestowed upon him all the Russian orders of knighthood, and caused him to be created a prince of the German empire, and to be knighted by the kings of Prussia, Sweden, and Poland, but failed, much to his regret, to obtain for him the orders of the Holy Spirit of France and the garter of England. He owned immense estates with 5,000 serfs in Russia proper and 40,000 in Polish Russia; his income and pensions were enormous; he received 30,000 rubles for the expense of his table alone. The property he left on his death amounted to over $25,000,000.

POTHIER, Robert Joseph, a French jurist, born in Orleans, Jan. 9, 1699, died there, March 2, 1772. He was judge successively of the court of the Châtelet in his native city, and of the *présidial*, and in 1749 professor of French law in the university of Orleans. Here he used to assemble his pupils at his own house to give them supplementary lessons and talk with them more familiarly about the subject of their studies, offered prizes to encourage the most meritorious, and frequently assisted them with his purse. His great aim was to harmonize legislation with divine and natural law. His principal work is his *Pandectæ Justinianeæ in Novum Ordinem digestæ* (3 vols. fol., Paris and Chartres, 1748-'52). In it he classifies all the texts of the Digest, which were arranged with little or no method in the original work, and elucidates conflicting decisions by thorough discussions and annotations. Both in America and England the authority of Pothier is greater than that of any other foreign jurist. His treatises on "Maritime Contracts," translated by Caleb Cushing (Boston, 1821), on "Contracts of Sale," by L. S. Cushing (Boston, 1839), and on "The Law of Obligations or Contracts," by W. D. Evans (Philadelphia, 1840), are regarded as authorities on their respective subjects.

POTOCKI, a noble Polish family, whose principal seat was in the former palatinate of Cracow, and which still holds large estates especially in Galicia and the Ukraine. Since the 16th century many members of this family have attained high positions in church and state in Poland. Jan and Jakób were generals in the time of Sigismund III.; Stanislaw, surnamed Revera (born about 1589, died in 1667), was chief hetman of the crown; and Waclaw (born in 1609) was a poet and translator of the *Argenis* of Barclay. Of the later members of the family the following are most distinguished. I. Stanislaw Felix, field marshal of the Polish artillery, born in 1750, died in 1805. He published with Rzewuski and Branicki, in 1792, the famous manifesto of Targovitza, and was active in promoting the objects of the confederation of that name with the aid of the empress Catharine II. in 1793; but after the uprising of Poland under Kosciuszko in 1794, he took refuge in the United States, and was condemned to death as a traitor to his country. The victories of Suwaroff restored him to his native land, and Catharine made him field marshal. He passed the rest of his life principally on his estates in the Ukraine, tortured by remorse for his political acts so disastrous to his country. II. IGNACY, grand marshal of Lithuania, cousin of the preceding, born in 1751, died Aug. 30, 1809. He was one of the framers of the constitution of May 3, 1791, and, when the invasion of the Russians took place, was obliged to flee to Prussia. The success of Kosciuszko called him back to Warsaw, where he became a member of the new government, but was captured by Suwaroff and conveyed as a state prisoner to Schlüsselburg. In 1796 he received his freedom from Paul, and went to Galicia, where he lived in retirement until the approach of Napoleon in 1806, when he was imprisoned a second time, but was released after a detention of a few months. III. STANISLAW KOSTKA, brother of the preceding, born in 1757, died Sept. 14, 1821. He was a man of ardent patriotism, was one of those who aided in framing the constitution of May 3, 1791, and after the second partition of Poland was arrested by order of the Austrian government. After an imprisonment of several months he was set at liberty, and from this time devoted himself to the study of the arts, sciences, and literature. At the organization of the duchy of Warsaw in 1807, he returned to his native land, became associated in the ministry, and in 1815 was made minister of public instruction. On account of his great talents as an orator he was called *princeps eloquentiæ*. He wrote several works, of which the most noticeable are his treatise "On Eloquence and Style" (4 vols., Warsaw, 1815), and an excellent although unfinished disquisition on the "Art of the Ancients" (3 vols., Warsaw, 1815), founded on the work of Winckelmann. IV. JAN, a historian, born in 1761, died by his own hand in 1815. He devoted himself to Slavic history, and for this purpose studied the various Slavic languages and travelled through the countries inhabited by that family of nations. His chief works are: "Travels in Turkey and Egypt in 1784" (Warsaw, 1788); "Essay on Universal History and Investigations in regard to Sarmatia" (5 vols., Warsaw, 1786); "Chronicles, Memoirs, and Researches for the Preservation of the History of all the Slavic Nations" (Warsaw, 1793); "Travels in Lower Saxony" (Hamburg, 1795); "Historical and Geographical Fragments in regard to Scythia, Sarmatia, and the Slavi" (4 vols., Brunswick, 1796); and "Early History of the Russian People" (St. Petersburg, 1802). These works were all written in French, and are especially important for the materials collected. Only 100 copies of each were printed. V. KLAUDYNA, Countess Dzialynska, wife of Count Bernard Potocki, born in Kurnik near Posen in 1802, died in Geneva, June 8, 1836. She hastened to Warsaw when the Polish revolution of 1830 broke out, and devoted herself to the care of the sick and the wounded with an earnestness and heroism which attracted universal admiration. She subsequently went into exile, and after her death her countrymen raised a monument to her memory in Geneva.

POTOMAC, a large river of the United States, constituting nearly the whole boundary between Maryland and Virginia, and formed by the junction of the North and South branches on the N. border of the latter state. The North branch rises in the Alleghanies in the north of Virginia, and the South branch in the Shenandoah range near the centre of the state. From the junction, which is about 20 m. S. E. from Cumberland, its course forms an irregular curve first N. E. and then generally S. E., until it reaches the city of Washington. Thence flowing S. and S. W., it expands into an estuary from 6 to 8 m. broad, and after a course of about 50 m. again changes to the S. E. for about 70 m. and enters Chesapeake bay 75 m. from the Atlantic, the entire length being nearly 400 m. Its principal tributary is the Shenandoah, which enters it just W. of the Blue ridge. Several other streams, but none of considerable size, also contribute to its volume. Of these the principal are the Savage and Monocacy rivers, and the Conegocheague, Patterson, Aquia, and Opichon creeks, all of which are navigable for short distances. The tide extends to Georgetown, 120 m. from its mouth, and it is navigable for ships of the line to the city of Washington. From its source to tide water the river has a great descent. There are a number of falls, including Houre's, the Shenandoah, Seneca, Great, and Little; and from Westport to Washington, about 220 m., the difference in its altitude is 1,160 feet. It abounds in beautiful scenery, and its passage through the Blue ridge at the junction of the Shenandoah at Harper's Ferry is renowned as, in the language of Jefferson, one of the most stupendous scenes in nature. The navigation of this river was an early object of attention, and by the operations of the Potomac company, incorporated by Maryland and Virginia in 1784, many improvements were effected.

POTOSI, a town of Grant co., Wis., on Grant river, about 2 m. from its entrance into the Mississippi, 80 m. S. W. from Madison, and 15 m. N. from Dubuque; pop. in 1860, 2,729. It is situated in a deep and narrow valley in the midst of lead mines, the products of which furnish the principal trade of the town. It is divided into 5 villages, Potosi proper, Van Buren, Rockville, British Hollow, and Vernon Settlement.

POTOSI, a department of Bolivia, bounded N. by Oruro and Chuquisaca, E. by Chuquisaca and Tarija, S. by the Argentine confederation, and W. by Atacama and Peru; area, 65,500 sq. m.; pop. in 1858, 281,229. The surface is an elevated table land, mostly rugged and mountainous, being traversed by numerous abrupt ridges, which increase in height toward the Cerro de Potosi. This mountain rises to the height of 16,037 feet above the sea, and is of conical form. The Cerro de Porco is situated at a little distance to the S. W. of it, and both are celebrated for mineral wealth. The country is generally of volcanic formation, but the

Cerro de Potosi is composed of quartzose rock. More than 5,000 mines have been opened in the summit in search of silver ore, and the top has been completely honey-combed and exhausted and the miners forced to carry on their operations lower down, where the great quantity of water has compelled them to abandon many of the richest veins. The country is barren and sterile, and the chief production is the silver obtained from the mines. Between 1556 and 1800 the mines of Potosi yielded $924,944,820.—POTOSI, the capital, is situated on the N. slope of the mountain of the same name, about 13,600 feet above the sea, in lat. 19° 35′ S., long. 65° 24′ W.; pop. in 1858, 22,850. The surrounding country is bleak and barren, and the atmosphere, except where tempered by the sun's rays, cold and piercing. It is the second city of Bolivia, and at one time covered a large extent of ground, and contained 150,000 inhabitants. The greater part of the town is in ruins, but the central square, which contains the government house, public offices, a church and convent, is still in tolerable repair. The mint is a very large edifice, and contains the machinery which in former times did a vast amount of work, but the present establishment only coins $2,000,000 annually. There are numerous churches, a college which accommodates 200 pupils, 4 primary schools, and a few others for the use of the children of the miners. The plaza of Ayacucho was constructed in honor of the battle which decided the independence of South America, and contains a lofty cylindrical shaft surmounted by a statue of Liberty. The town is supplied with water from 37 tanks, 8 or 10 m. distant, which were constructed at great expense about 200 years ago. All supplies have to be brought from a distance, as the country in the immediate neighborhood produces nothing, and considerable quantities of various English and French manufactures are consumed there.

POTOSI, in Mexico. See SAN LUIS DE POTOSI.

POTSDAM, a township and village of St. Lawrence co., N. Y., on Racket river; pop. in 1860, 7,262; of the village, 2,422. It is principally noted for its extensive quarries of sandstone used for flagging and building, much of which is sent to Hamilton, C. W. Abundant water power is supplied by the Racket river, and several manufactories are in operation. The Potsdam and Watertown railroad and its connections afford communication with all parts of the state as well as with the East and West. The township contains a bank, a printing office, and 10 churches, viz.: 1 Baptist, 1 Catholic Apostolic, 1 Episcopal, 3 Methodist, 2 Presbyterian, 1 Roman Catholic, and 1 Universalist.

POTSDAM, a town of Prussia, situated on the Havel, which here forms a small lake, 17 m. S. W. from Berlin; pop. in 1849, 39,964. It contains a royal palace begun in 1660. The apartments occupied by Frederic the Great are preserved in the same state in which they were left by him. Sans Souci, the favorite residence of the same monarch, lies near the town. It is a long low building erected in 1745–'7. It contains the apartments occupied by the king and Voltaire, as well as Frederic's clock, which was stopped at the instant of his death. Another palace in the same grounds was built after the 7 years' war; and at no great distance is the beautiful villa of Charlottenhof, built in the Italian style. Other royal residences in the neighborhood of Potsdam are the marble palace, and the villa on Peacock island in the Havel. Potsdam is connected by railway with Magdeburg and Berlin. It occupies a beautiful position, and has the advantage of every possible variety of scenery in its neighborhood. The manufactures include cotton, lace, silk, linen, woollen, leather, porcelain, chemical substances, and firearms.

POTTER, a N. co. of Penn., bordering on N. Y.; area, about 1,100 sq. m.; pop. in 1860, 11,467. It has an elevated and mountainous surface, and is drained by the head waters of the Allegheny and the Genesee, and by several branches of the Susquehanna, as well as by a number of creeks. Much of it is covered by pine forests, and lumber is largely exported. The productions in 1850 were 13,359 bushels of wheat, 16,562 of Indian corn, 80,814 of oats, 8,717 tons of hay, 134,887 lbs. of maple sugar, 22,046 of wool, and 168,677 of butter. There were 8 grist mills, 50 saw mills, and 1,026 pupils attending public schools. Capital, Coudersport.

POTTER. I. ALONZO, D.D., LL.D., an American clergyman, bishop of the Protestant Episcopal church in Pennsylvania, born in Beekman (now La Grange), Dutchess co., N. Y., July 10, 1800. He was graduated at Union college, N. Y., in 1818, became a tutor in the college in 1819, and was elected professor of mathematics and natural philosophy in 1821. Having studied for the church, he was ordained deacon in April, 1821, and priest in Aug. 1824. In 1825 he was elected president of Geneva (now Hobart) college, N. Y., but declined the post. He was invited to the rectorship of St. Paul's church, Boston, in 1826, where he remained till 1831, in which year he became vice-president and professor of moral philosophy in Union college. He received the degree of D.D. from Harvard and Gambier colleges, and in 1846 that of LL.D. from Union college. Having been chosen bishop of Pennsylvania, he was consecrated Sept. 23, 1845. He has published "The Principles of Science applied to the Domestic and Mechanic Arts," &c. (12mo., New York, 1841); "Political Economy, its Objects, Uses, and Principles considered" (18mo., 1841); "Handbook for Readers and Students" (18mo., 1847); "Discourses, Charges, Addresses," &c. (12mo., Philadelphia, 1858); and, in conjunction with George B. Emerson, "The School and Schoolmaster" (12mo., New York, 1844). II. HORATIO, D.D., LL.D., brother of the preceding, an American clergyman, bishop of the Protestant Episcopal church in the diocese of New York, born in Beekman, Dutchess co., N. Y., Feb. 9, 1802. His early education was obtained at the academy in Poughkeepsie, N. Y.; he was graduated at Union college in 1826, ordained deacon in July, 1827, and priest the next year. In 1828 he was appointed professor of mathematics and natural philosophy in Washington (now Trinity) college, Hartford, Conn., where he spent 5 years. While in Hartford he was invited by Bishop Moore to become his assistant in the Monumental church, Richmond, Va., but declined. In 1833 he was called to the rectorship of St. Peter's church, Albany, N. Y. In 1837 he was elected to the presidency of Trinity college, Hartford, but declined. He received the degree of D.D. from Trinity college in 1838; of LL.D. from Geneva college, N. Y., in 1856; and of D.C.L. from the university of Oxford in 1860. On the death of Bishop Wainwright in 1854, Dr. Potter was chosen provisional bishop of the diocese of New York, and consecrated Nov. 22, 1854. By the death of Bishop B. T. Onderdonk, April 30, 1861, he became bishop of the diocese.

POTTER, Hazard Arnold, M.D., an American physician and surgeon, born in Potter township, Ontario, now Yates co., N. Y., Dec. 21, 1811. He was graduated M.D. at Bowdoin college in 1835, and began the practice of his profession in Rhode Island, but after a residence there of a few months returned to his native town. In 1853 he removed to Geneva, N. Y., where he enjoys a high reputation as a surgeon and consulting physician. In 1845 he trephined the spine for depressed fracture of the arches of the 5th and 6th vertebræ, and has performed the same operation twice since. He has performed ligature of the carotid artery 5 times, 4 times successfully, removed the upper jaw 3 times and the lower twice, and successfully removed the 5th rib on the left side from the sternum to within 3 inches of the spine, for caries of the bone accompanied by abscess in the left hypochondrium. Dr. Potter was early convinced of the safety of operations within the abdominal cavity, and in 1843 performed gastrotomy for the relief of intussusception of the bowels with perfect success. He has removed fibrous tumors of the uterus from within the abdominal cavity 5 times, and successfully in 3 cases. He has extirpated by ovariotomy 8 ovarian tumors, 5 of them successfully, and in one of the successful cases both ovaries were removed at the same time. In another case, also successful, the operation was repeated upon the same patient twice with an interval of 17 months; each time the tumor and its contents weighed nearly 30 pounds. Dr. Potter was also one of the first surgeons who called attention to the presence of arterial or bright red blood in the veins of the parts paralyzed by depressed fracture of the cervical vertebræ, which he first observed in 1837. In these cases he believes that if the patient lives the ganglionic or sympathetic system, after a few weeks, assumes that function of the cerebro-spinal axis which regulates the processes of assimilation and nutrition. In a case of amputation at the hip joint reported in the "New York Journal of Medicine and Collateral Sciences" (June, 1854), he introduced a method of amputation in such cases which was at that time deemed novel. Proceeding as if for amputation at the upper third of the femur by flaps, he extended the external incision up to the trochanter major, and dissected out the head of the bone, by this method obtaining among other important advantages a large muscular stump for an artificial limb. He has repeated the same operation successfully since.

POTTER, John, D.D., an English prelate, born in Wakefield, Yorkshire, in 1674, died in 1747. He was the son of a linen draper, and was graduated at University college, Oxford, in 1692, and in 1694 was chosen fellow of Lincoln college and took orders. He was known as a scholar very early in life, his edition of Plutarch's *De Audiendis Poetis* having been published when he was only 19. His best known work, "Antiquities of Greece," was published in 1697, when he was 23 years of age. He was made D.D. in 1706, and soon after chaplain in ordinary to Queen Anne, and in 1708 was chosen regius professor of divinity and canon of Christchurch, Oxford. Seven years later he became bishop of Oxford, and in 1737 archbishop of Canterbury. His theological works were collected in 3 volumes (Oxford, 1753).

POTTER, Louis Joseph Antoine de, a leader in the Belgian revolution of 1830, born in Bruges, April 26, 1786, died there, July 22, 1859. He was born of rich and noble parents, spent his youth partly in Holland, partly in Germany, and lived from 1809 to 1811 in southern France, and the 13 following years in Italy, where he devoted himself to the study of church history. In 1824 he returned to Brussels, was one of the bitterest opponents of the king and the ministry, and for his free expression of opinion was sentenced in 1828 to 18 months' imprisonment and a fine of 1,000 florins. Considered by the people as a martyr, he was borne in triumph to his prison, and there wrote a pamphlet on "The Union of the Catholics and the Liberals." For other publications of a revolutionary character he was tried on a charge of high treason, and in April, 1830, was sentenced to 8 years' banishment. After the French revolution of July he took up his residence in Paris, and from there addressed a letter to the king of the Netherlands, advising him to constitute Belgium a separate state. Upon the breaking out of the Belgian revolution in September he returned to Brussels, where he was received in triumph and made a member of the provisional government. He favored the establishment of a republic, but was opposed by his colleagues and defeated by a large majority in the national congress. After the dissolution of the provi-cal government he was obliged to flee to France, and took no farther part in political affairs. The most important of his numerous works is his "History of Christianity" (8 vols., Paris, 1836-'7).

POTTER, Paul, a Dutch painter, born in Enkhuysen in 1625, died in Amsterdam, Jan. 15, 1654. He was instructed in his art by his father, Peter Potter, an artist of moderate ability, and as early as his 15th year had so great a reputation for his cattle pieces, that he could with difficulty supply the demands of his patrons. He excelled all contemporary artists in the painting of cows, sheep, goats, and other domestic animals, which he invariably studied from the life, making the landscape and other parts of the picture subordinate to them. Some of his best works were executed for Frederic Henry, prince of Orange, who had a high admiration of his genius. He was ardently devoted to his art, and found his chief relaxation from the labors of the studio in sketching from nature during his walks in the fields. Excessive application undermined a naturally delicate constitution, and he died at the age of 29 in the very maturity of his powers. His best pictures are of small size, exhibiting exquisite finish, a free handling, and brilliant effects of sunshine; but some are painted of the size of life. Of the latter class a notable example is the picture known as the "Young Bull," now in the museum of the Hague. Of his cabinet-sized pictures one of the finest is a landscape with cattle and figures in the possession of the marquis of Westminster. Another picture representing 4 oxen in a meadow, which sold in 1750 for £25, was bought in 1815 by the emperor of Russia for £2,500. Many similar instances of an advance in the value of his works are recorded. He executed some admirable etchings.

POTTERS' CLAY. See Clay.

POTTERY and PORCELAIN, baked earthenware, the former opaque and of coarse quality, the latter translucent and of fine quality. The name pottery is said to be derived from the low Latin *potus*, a pot, and porcelain is supposed to be from the Italian *porcellana*, a drinking cup. The manufacture is often called the ceramic art (Gr. *κέραμος*, potters' earth), and its products fictile ware (Lat. *fingo*, to form). The fashioning of various utensils in clay and baking them either in the sun or by fire has been practised from the remotest periods, and by the ancient Egyptians the art was attributed to the gods, showing that its date preceded their records. Frequent allusions are made to it in the Old Testament, and the relics found among the ruins of different eastern countries show that the manufacture was practised among nations widely separated from each other by religion, manners, and laws. Indeed it is to such fragile memorials of the past that we are indebted for much of the knowledge we have of the history, customs, and superstitions of the ancients. Upon the bricks and articles of pottery found in Egyptian, Assyrian, and Babylonian ruins are often preserved hieroglyphics (see Cuneiform Inscriptions) of no little historical interest; and upon the walls of the tombs in Egypt are pictured the various processes employed in the production of the earthenware utensils. These, though rudely conducted, were similar in principle to the methods now in use—the potters' wheel, which is also alluded to in the Old Testament, being represented, as well as a furnace in which the articles were baked. These articles were of great variety, some being intended for domestic, some for religious, and some for funereal purposes. Those of each nation possess a distinctive character, while a general resemblance is perceived in their quality and uses. Among the Egyptians vases or jars appear to have been the prevailing utensils for a great variety of purposes, and in eastern countries they are still employed in the place of numerous wooden and metallic vessels and baskets of more advanced nations. These were of all sizes, from several feet in height down to scarcely an inch, and variously shaped to suit the purposes required. Some were water jars with wide necks, and some with contracted throats furnished with spouts. Wine, oil, honey, milk, drugs, ointments, grain, and numerous other articles had their peculiar-shaped vases or jars, and the several tradesmen and artificers employed vessels specially adapted to their uses. Thus, to this ancient people earthenware was obviously of far greater importance than it is to us. Many articles were largely manufactured and esteemed by them of great value, which have long since ceased to be used. Such are those employed in their funereal and religious rites; vases for the mummies of the sacred ibis and other animals, and others for containing the portions of the human bodies removed in the process of embalming; models of mummy cases kept by undertakers to show to the friends of the deceased, as described by Herodotus; *shabti* or sepulchral mummy-like figures to be deposited with the deceased in the tomb; and singular conical-shaped sepulchral ornaments, upon which, as upon the *shabti*, were inscribed various legends relating to the dead, or of more general interest. The tombs were the receptacles of a multitude of articles supposed to have been deposited for the use of the deceased in the future life. All these were made in terra cotta or unglazed common ware, and the color was red; their date goes back as far as the 3d and 4th dynasties, or from 2,000 to 3,000 years B. C. Some of the finer articles appear to have been polished by some mechanical process. Glazed ware was in use in the 6th dynasty; the glaze appears to have been formed of pulverized silex and soda and colored by various metallic oxides; the blue tint discovered and used at this early period retains its lustre to the present time, and is unsurpassed by the productions of modern art. Beside these were numerous articles worn for ornament, as beads, amulets, &c., which from the numbers preserved must have been manufactured in wonderful profusion. The specimens of Assyrian pottery that have been preserved are for the most part bricks and inscribed tiles, cylinders, and prisms. These were used as tablets for preserving the records of the Assyrian kings, and in their reigns constituted with other similar documents the libraries and the archives of the monarchs. Glazing and enamelling the surface of bricks, tiles, and other articles of earthenware, were practised by the Assyrians, but not with the skill of the Egyptians. The Babylonian relics of this class are similar to those of Assyria. Bass-reliefs in terra cotta appear to have been more common, and generally produced in moulds; they represent figures of men and animals, and some of great interest for the artistic execution have been modelled by hand. Large images were made in clay and covered with brass or bronze; to such allusion is made in the book of Daniel. The golden idols were probably formed of clay upon the potters' wheel and overlaid with gold. Coatings of this metal and of silver were applied not only to such objects, but to the bricks intended for the principal edifices.—In Europe the most ancient pottery worthy of notice was that of the Etruscans. As far back as the 7th and 8th centuries B. C. their vases, of a coarse dark brown ware, in great variety of sizes, adorned with figures in relief, were fabricated in forms of such perfection and beauty as to entitle them to the rank of works of art. In the productions from the 5th century B. C. the effect of intercourse with the Greeks is perceived in the change from the native style to imitations of the Hellenic. The Etruscan relics of this class are chiefly vases of black, brown, red, and yellow terra cotta; and they owe their preservation to the same custom as that of the eastern nations of that period of interring these articles in the sepulchres with the remains of the dead. The sarcophagi themselves were constructed of slabs of pottery, and two of them preserved in the British museum are elaborately ornamented on the sides and ends with bass-reliefs, and on the covers with full-length effigies of Etruscan females. A vase, also in the museum, is a model of an ancient Etruscan cottage, with a movable door and a vaulted roof imitating the wooden rafters. This probably contained the ashes of some distinguished person, and being placed in another large two-handled vase, the whole was buried in the earth.—The pottery manufacture was quite as important in Greece from the 5th to the 3d century B. C. as in any of the other countries named; and it included even a greater variety of articles which were finished in higher styles of art. At Athens and other cities of Greece there were at times exhibitions of these productions, by which a spirit of competition was incited. Most of the relics now preserved are those that were deposited in the tombs, chiefly vases; among other articles small terra cotta figures, resembling modern plaster casts, have been found near the sites of some of the cities in great abundance. These and the architectural ornaments were painted in appropriate colors by artists specially devoted to this object. Lamps of a fine paste and delicate construction and bearing inscriptions are found, and those that may be referred to the period of the Roman dominion are very numerous. Vases, called *amphoræ*, usually of cylindrical or egg shape, were universally employed for the storing and transportation of oil and of other commodities, as also for different domestic purposes; and upon their handles were stamped trade marks and other devices. Ornamental vases also of remarkably graceful forms are very numerous, imitating the figures of animals, heads of Bacchantes, &c., also highly decorated with figures in relief, and with elaborate coloring. In many of them the colors are protected and their brilliancy increased by a transparent glaze, composed of an alkali, silex, alumina, oxide of iron, and lime, in proportions not unlike those found in volcanic ashes, thus suggesting that these may have been spread over the surface and fused. The ceramic art declined in Greece from the 3d century B. C. The introduction by Alexander the Great of vases made of the precious metals led to their substitution for the better varieties of fictile vases. Those of metal soon became common in Sparta; in the 1st century B. C. they had entirely superseded those of earthenware, so that in the time of Augustus the latter were antique curiosities. The finest specimens of Greek vases, among which are many elaborately ornamented with pictorial devices representing scenes of historical or mythological character, are found in Etruria, and were the work of Grecian artists removed thither, or of Etruscan artists educated in Greece. Some of similar character are also found in central and southern Italy. Beautiful examples of these are preserved in the British museum and in the museum of practical geology in London.—Pottery was applied by the ancient Romans to the construction of statues and architectural ornaments; and when marble and bronze were at later periods substituted for it by sculptors, the models were still made in terra cotta. A great variety of articles for domestic purposes made of this material are enumerated by Birch in his "History of Ancient Pottery" (London, 1858). Vases, as with the eastern nations, were still the most numerous and useful products of this art. In general they were made with less regard to beauty of form and ornament than to the purposes for which they were designed; and they are consequently far inferior to the Grecian manufacture of the same period. The finest ware is that known as the Samian or Aretine, of the potteries of Samos and Aretium, now Arezzo, in Tuscany. The latter was produced from the 1st to the 3d century A. D., and was widely scattered throughout the colonies established by the Romans. Even in Britain relics of it have been found in considerable quantity at the stations occupied by the Roers. The ware is remarkable for the rich d color of its paste like that of sealing wax, nd for the thorough and admirable manner in hich it must have been worked. The color oth of the paste and glaze was derived from xide of iron. The articles are thin and deli- ate, and wherever found are remarkably alike form, structure, and style of ornamentation. hey were evidently highly valued, as frag- ents have been found neatly riveted together ith lead. Bowls were the most beautiful and laborated of these articles, and upon their ex- ernal surface are seen arabesques and pictorial llustrations of the religious habits and customs f the people. These are sometimes moulded n relief, and sometimes impressed in intaglio rom a stamp of the figure in relief. Such tamps have been found together with the odelling tools, styles, punches, and other arti- les employed.—Little is known of the early ottery manufacture of the East. The Chinese scribe its invention to the emperor Hoang-ti, 2700 B. C., and the first production of porce- ain they fix in the Han dynasty, about 185 B. C. Common pottery is manufactured to an mmense extent for the requirements of the mbler classes, and earthenware vessels of ery large size are employed by wealthy Chi- ese as reservoirs for gold fish and aquatic lants, and for storing grain, &c.; but porce- ain has extensively supplanted it as an article f export. Porcelain is used not merely for do- mestic utensils, but also for slabs and tiles, with which costly edifices are coated. Such was the famous pagoda of Nankin, destroyed in 1856. Marco Polo, in the latter part of the 13th century, was struck with the extent of the porcelain manufacture in China, and the extraordinary cheapness of the ware, 8 cups of which could be purchased for a Venetian groat. The finest articles were not exported, and great care was taken to prevent strangers from learning the processes of manufacture. The French Jesuit D'Entrecolles was the first person permitted to witness these, and from what he saw and learned from Chinese books on the subject he was enabled to send to France in 1712, from a seat of the manufacture at Jao-tcheou, such an account of the operations that, aided by the specimens of the two most important materials, also sent, Réaumur succeeded in learning the true character of the ware and how it might be made in France when suitable materials should be discovered. Such ware was afterward produced in the Sèvres porcelain. The historical facts above cited relative to the manufacture of porcelain in China are from the work of M. Stanislas Julien, an eminent Chinese scholar, who published in 1856 in Paris a translation of a Chinese work on the history of the porcelain of King-te-chin, to which he added an elaborate preface and notes from other sources. From this account it appears that there are at least 50 establishments devoted to the manufacture; and at the great works of King-te-chin, which for more than 5 centuries have enjoyed the special patronage of the emperors, 3,000 furnaces are now in constant operation. Among the choicest productions are the vases known as "crackle," the glazing of which is covered with a network of fine cracks produced by sudden chilling at a certain stage of the baking. Being then washed over with a colored glaze, which is sometimes ruby red, the cracks are filled with it, producing a beautiful effect. In another variety the color is brought out only when the vessel is filled with a liquid. This is effected by painting the design on the inner surface of a very thin cup, and washing over this more of the paste, so that the figures are enclosed between two surfaces. The outer surface after the baking is ground nearly to the colored figures and is then glazed. The liquid acts as a foil to bring the design into view. In another the design is plainly visible upon a perfectly smooth surface of pure white; an effect produced by impressing the design from a mould in relief and then restoring the smoothness by a thick glaze of fine consistence. The egg-shell ware is very ancient and celebrated. Cups, jars, vases, &c., are made of this, so thin and delicate as to be almost transparent. At one time in the 15th century it was produced as thin as bamboo paper. It is sometimes pure white, sometimes of cream color, and again of an exquisite shade of blue derived from cobalt. The chief domestic sources of this color were exhausted in 1500, and since that time the Chinese have procured their best cobalt from Europe, principally from England. The porcelain manufacture of Japan is of similar excellence to that of China, and is supposed to be nearly as ancient.—Upon the American continent the manufacture of pottery is also traced back to remote periods, and the productions of some of the South and Central American aborigines and of the "mound builders" of the West are particularly interesting. The works of the ancient Peruvians that still exist testify to a high degree of skill as attained by their potters, and the varied uses which the articles in pottery served. Drinking vessels and flasks appear to have been the most common productions, and the latter were frequently provided with two necks, a characteristic of such vessels among both the ancient and modern potters of South America. The paste is usually red or yellow, and ornamented with figures in black, red, white, and yellow. Many of the flasks are beautifully formed with long delicate necks, and others are heads of animals, as the jaguar. Others have the forms of birds and of some of the native fruits. In rare cases the human face is seen in relief on their surface, and some are true vase busts. A figure of a drinking vessel given by Ewbank in his "Life in Brazil," about 9 inches in height, is a head of the celebrated cacique Ruminhauy, and probably correctly represents his appearance, as it introduces particular marks, such as the loss of a tooth and a wound in the cheek, The pottery now made by the Peruvian Indians is far inferior in quality and form to that of ancient times. Some peculiar forms common to the ancient wares Ewbank esteems worthy of imitation, such as the double-necked "monkey" or jug common in Brazil, one small neck being designed for admitting air, while the liquid is poured out from the larger one. He states that the production of crockery in Brazil is enormous, and that cargoes of boats are frequently seen almost entirely composed of the *talhas* or large water vessels. These are made of a light red porous clay, are unglazed, and hold from 10 to 15 gallons each. The wares of Bahia are much superior to those of Rio. The ruins of Central America have furnished earthen vessels well baked, ornamented with different colors, and covered with a vitreous glaze such as was unknown in Europe for many centuries after their probable date. The Mexicans also had early attained a high degree of perfection in their pottery. That of the Cholulans, according to Herrera, was extremely delicate, rivalling in beauty the Florentine manufacture; and that of the Tlascalans was unsurpassed in its excellent qualities by any in Europe. About the ruins of New Mexico and Chihuahua relics of these ancient wares are found in the greatest abundance. For miles around certain ruins in the country of the Pimos Indians the surface is found strewn with broken pottery of fine quality. The colors are red, black, and white, and many of the articles are painted on the inside, while modern Indian and Mexican wares are painted on the outside. Among the relics found in the western mounds by Messrs. Squier and Davis, and described in the 1st volume of the Smithsonian "Contributions to Knowledge," are very curious and interesting specimens of pottery. Some of these were earthenware pipe bowls moulded in clay in the form of various animals and birds, some of which are not found nearer than the gulf of Mexico; others were of the form of the human head and very skilfully executed; but the best pipes were mostly carved in stone. The vases from the mounds were well executed, thin, and handsomely ornamented. Some of the finest from Ohio are dark brown and highly polished; those from the southern mounds are coarser. Most of them appear to have been merely hardened over a fire, not burned in a kiln. In his account of the "Aboriginal Monuments of New York" ("Smithsonian Contributions to Knowledge," vol. ii.) Mr. Squier remarks upon the great profusion of fragments found upon the site of every Indian town in that state and the rarity of entire vessels. The shape of the articles was like that of a gourd, the bottoms rounded, rarely flat, and protuberances or a groove around the vessel were supposed to be made to facilitate their being suspended by a cord. The capacity of the vessels was from one to four quarts, but some of them were much larger. They were generally very plain, though some were elaborately finished if not tastefully ornamented with dots and lines, evidently made with a pointed stick or bone in the material when soft.—Few among the most savage nations are so low in intelligence as not to have manifested more or less skill in the manufacture of pottery wares of some sort. Some have not attained the art of baking their productions in the fire, but merely dry them in the sun. Pickering states that the Feejeeans produce articles of large size and of uniform shape and dimensions, and glaze them with the resin of a tree.—After the decline of the Roman empire pottery as a decorative art was lost in Europe. The Arabs introduced it into Spain on their conquest of that country in the early part of the 8th century, and also into Sicily in the next century. Their productions were for the most part tiles for pavements and for the decoration of the walls of buildings, a branch of the art in which they excelled, giving to the slabs a yellowish white enamel of high lustre, and ornamenting them with elaborate designs in gorgeous colors, yet harmoniously blended, representing, with scrolls, arabesques, and inscriptions of oriental origin, figures of birds and other animals of the country, and occasionally the local coat of arms. With such tiles they adorned the Alhambra, and in Sicily the great mosque at Palermo. Into Italy also the manufacture gradually spread, and by the 14th century the art was there improved as well by native inventions as by the introduction of Grecian processes from Byzantium. In Pesaro at this period was practised what may be regarded as the basis of the celebrated Majolica ware, the overlaying of an opaque white surface upon the common pottery groundwork. This foundation being partially baked, it was covered by immersion with a thin coating of a pure white clay, with which were intermixed oxides of lead and tin. The baking was then completed in the kiln. This style was greatly perfected by the skill and genius of the Robbias, uncle and nephew, of Florence. For two centuries the finest works in pottery in Europe were of Majolica ware, characterized by its peculiar lustrous enamel, and named it is supposed from the island of Majorca, where similar work had been produced by the Moors. The greatest variety of utensils were made of it, and in their ornamentation were employed the designs of the most distinguished artists. To such extent was this carried that the articles came to be prized only for their decorations, and their utility was lost sight of. Urbino, Gubbio, Castel-Durante, and Faenza were places especially famous for this ware, and the term *fayence* by which also it is designated was probably derived from the last named city. In the 16th century this class of pottery manufacture was introduced into Nuremberg in Germany and Nevers in France, and was also practised with great success at Saintes by Palissy "the Potter," whose colored enamels were produced upon a tin glaze. But in both France and Germany other styles of enamelled pottery had been manufactured for some centuries previously. The Dutch have been famous from the 15th century for their glazed colored tiles and other pottery produced at Delft and its vicinity. From that period they continued to be largely introduced into England for churches and expensive mansions; and in the 16th century their dishes for dinner service were well known throughout Europe. The Dutch in their ornamental designs appear to have copied the old porcelain of Japan, with which they were early acquainted.—Chinese porcelain was imported into Europe by the Portuguese in the early part of the 16th century, and was known as china. The Dutch and English afterward brought the ware from the East, and as it became known every attempt was made to ascertain the secret of its beautiful translucency and to produce the same ware in European countries. Böttcher, an apothecary's assistant at Berlin, a refugee in Saxony on account of his reputation as an alchemist, first discovered the nature of the material, and succeeded in producing in 1709 a genuine white porcelain of natural clays without metallic fluxes. The elector Frederic Augustus was so much pleased with it, that he established a manufactory at Meissen of which Böttcher was made director. In this good porcelain was produced in 1715 from the kaolin of Aue in the Erzgebirge. Such was the origin of the porcelain works of Dresden, from which the art extended to Vienna and Berlin, where were founded in 1720 and 1751, respectively, the works in which the famous wares of those places have since been produced. The experiments of Réaumur, already referred to, resulted in the invention of a compound of earths and fluxes, which when partially melted in the fire formed a material resembling porcelain, and known as soft porcelain. Works for manufacturing the ware were established in 1735 at Chantilly, and 10 years later at Vincennes. In 1756 by royal sanction the works were removed to Sèvres, where after 1769 they were supplied with true kaolin (see CLAY), and also with the feldspar or petunse which had been discovered with it near Limoges. Porcelain was made in England in the middle of the last century, first at Chelsea under the patronage of George II. and the duke of Cumberland, also at Stratford le Bow, Derby, Plymouth, Worcester, and other places. The works at Worcester, patronized by George III., have been styled since 1788 the royal porcelain works. They have continued in operation to the present time, and their productions have been famous for their beautiful translucency and the rich variety of their colored and gilded decorations. Staffordshire is also an important seat of the porcelain manufacture. There also are the most extensive potteries in England, established upon the same spots that were occupied for similar purposes by the potters of the period of the Roman occupation. In 1650 Burslem in this district was noted for its various fictile productions, and Newcastle-under-Lyme for its manufacture of tobacco pipes. Salt glazing was discovered here in 1680. In 1730 Josiah Wedgwood was born at Burslem, and 30 years afterward he had produced specimens of the peculiar cream-colored ware, which by permission of Queen Charlotte he was allowed to designate "queen's ware," and which soon came to be applied to a great variety of articles. (See BISCUIT, and WEDGWOOD.) By means of his chemical acquirements and extraordinary skill he succeeded in imitating in porcelain famous cameos and antiques in precious stones, as seals, and his artificial jaspers were wonderful facsimiles of the natural mineral. His imitations of the famous Portland vase, of which he produced 50 copies, were hardly surpassed in beauty by the original itself. In 1852 the Staffordshire potteries comprised 133 establishments, which gave employment to more than 60,000 persons. All branches of the art are there carried on, including the production in the ancient style of inlaid tiles and moulded architectural terra cotta. The "statuary Parian" or "Carrara biscuit" ware, for statuettes and other objects, was invented there in 1845. In these potteries were consumed in 1855 about 750,000 tons of coal; the value of the gold used for the ornamentation of the articles was about $250,000. In 1859 the manufactured ware sent out of the district amounted to over 110,000 tons, which, at the average value of £25 per ton, was worth £2,500,000. A very large proportion of the exports are to the United States.—In the United States, such is the cheapness and the excellence of the imported pottery, the manufacture has made little progress, notwithstanding good materials for different sorts of ware are sufficiently abundant. Small establishments for the production of the commoner sorts of earthenware have long been in operation in nearly all the states, and some have engaged in the manufacture of stone or white ware. At the Jersey City potteries porcelain was made in 1816, and again at an establishment in Philadelphia, which closed in 1836; and at a pottery at Liverpool, Ohio, a small amount of the "Parian" ware has been produced. The Jersey City works are now engaged in the manufacture of the cream-colored or "CC" ware, the clays for which are obtained from the region of upper secondary rocks about Amboy. In New York city and Brooklyn several potteries are in operation. Two at Greenpoint, Brooklyn, produce porcelain of fair quality. The New York city potteries in 18th street are largely engaged in the manufacture of the common cream-colored, dipped, and white granite wares, employing about 100 workmen and producing about $75,000 worth per annum. The blue clay used at these works is from Woodbridge, N. J.; china clay from England and Delaware, and some from South Carolina; and the feldspar is from Middletown, Conn. The common salt-glazed and red wares are made in several other potteries in the city. The other most important potteries in the United States are at Trenton and Perth Amboy, N. J., East Liverpool and Zanesville, Ohio, and East Peoria, Ill. At Bennington, Vt., there was also a large establishment, recently stopped. Coarse pottery in large quantities has been for some time manufactured at Hamburg, S. C. The imports of pottery of all kinds into the United States during the year ending June 30, 1859, amounted to $3,485,032, of which $2,555,770 was from England and $599,080 from France.—The following table presents the order of the introduction of the several sorts of pottery in different countries:

B. C.
2600—Pottery in China.
2122—Bricks with true glaze at Babylon.
1900 to 1800—Egyptian pottery.
1500—Coræbus, inventor of pottery.
1200—Invention of potter's wheel by Talus (very doubtful).
900—The Samian potters.
715—College of potters instituted by Numa.
500—Etruscan vases.
434 to 284—Græco-Etruscan vases.
Before the Christian era, but of uncertain date, are the Gaulish, Celtic, Breton, German, and Scandinavian pottery.
Very ancient, possibly before the Christian era, is the hard Mexican pottery, with hard silico-alkaline glaze.
A. D.
150—Roman pottery with red glaze.
1st to 3d century—Dull Gallo-Roman pottery.
711 to 780—Varnished Arab pottery.
1100—Lead glaze.
1146—Enamelled fayence.
1300—Lead and tin glaze.
1415—Luca della Robbia enamelled fayence.
1511 to 1540—Majolica of Orazio and Flaminio Fontana.
1540—Flemish stoneware.
1555 to 1600—Bernard Palissy enamelled fayence and Delft ware.
1695—French tender porcelain, first manufacture tolerably fine.
1706—Böttcher made porcelain in Saxony, whence the art spread all over Germany from 1710 to 1760.
1725—English fine earthenware with flint.
1741—French tender porcelain, second manufacture, very fine.
1745—English tender porcelain.
1763—Wedgwood, fine earthenware.
1771—Sèvres, hard porcelain.
1800—Spode brought both the paste and glaze of English tender porcelain to perfection. Phosphate of lime and boracic acid introduced.
1830—Fine earthenware brought to perfection. Introduction of kaolin into the paste, and hardening of the glaze.

—The articles included in the term pottery are of a great variety of composition as well as of figure and uses. Bricks and tiles (described in this work under their own names) are examples of the coarsest wares; and from these there is a regular gradation, commencing with the common red earthenware through the varieties of stoneware, to the different sorts of porcelain. These varieties are too numerous to be particularly designated in this article. The following general divisions may be recognized: 1. Soft pottery, including the wares of open, porous structure, composed of natural mixtures of sands and clays, or of the latter artificially tempered with sand, always colored, usually fired at a moderate temperature, and either glazed or not. The texture is usually not homogeneous. These wares are bricks, tiles, drain pipes, chimney pots, Hessian crucibles, and a great variety of ordinary red pottery. 2. Fine earthenware, composed of finer materials more carefully selected, containing no ingredient used as a flux, the mass white, hard, and sonorous, of earthy fracture, and covered with a crystal glaze containing lead or borax. Delft ware is an inferior variety, formed chiefly of potters' clay and marl. 3. Stoneware, fine and common, the former including the Wedgwood wares. They differ from fine earthenware by the use of Cornish stone as a flux, the heat employed in firing being sufficient to partly fuse it; and from porcelain by the almost entire absence of translucency. No glazing mixture is applied to them, but sometimes a glaze is otherwise produced. Common stoneware is produced at a higher temperature and by a simpler process. It is dense and vitreous enough not to require glazing, but this is sometimes done by throwing salt into the kiln, which vaporizes and forms with the silica a soda salt. It is of various natural colors, or others are imparted to it by external applications. 4. Porcelain, the hard, translucent variety, prepared of carefully selected kaolin and pulverized quartz and feldspar, and covered with a glaze of similar composition, but somewhat more fusible than the mass, with which it becomes intimately incorporated at the high temperature employed in the baking. The true hard porcelains are distinguished for their infusibility. The so called soft or tender porcelain formerly produced at Sèvres is not of the nature of pottery, but more like glass, into which it would melt at the high heat at which true porcelain is baked. It contains no clay, but is composed of fusible mixtures of silica and alkaline and earthy fluxes, covered with a lead glaze of harder consistence than the mass, but softer than true porcelain. The term soft, however, has principal reference to the readiness with which the material softens in the fire. The English tender porcelain is also a very fusible mixture, containing a large proportion of bone ash, and glazed with oxide of lead and borax. Cornish granite and kaolin, however, form its basis. The bone ash, composed of phosphate of lime, carbonate of lime, and a little magnesia, makes an excellent flux; and the phosphoric acid in baking diffuses itself through all the materials, uniting them into a translucent enamel, which has little tendency to lose its form by shrinking. This is the only kind of porcelain made in England, for the reason chiefly that suitable "seggars" for holding the articles in the kiln, and capable of withstanding the intense heat required for producing the hard porcelain, cannot be cheaply enough obtained.—The preparation of these varieties of pottery depends upon a multitude of mixtures of clays, pulverized quartz or flints, and feldspar, and sometimes of coloring materials for the mass or body, beside numerous glazes more or less complicated in their composition. The enamels and various styles of ornamentation add largely to the range of the subject; and but few of the topics embraced in it can be particularly noticed. At the Staffordhire potteries the clays and other materials are furnished from different parts of Great Britain, the fire clays coming from the coal measures in the vicinity of the works, the kaolin and Cornish stone from Cornwall, and flints and chalk from the chalk formation at Gravesend and New Haven. Common plastic clay also is obtained from different sources, and steatite or soapstone is brought to be introduced into the mixtures. For the porcelain and fine earthenwares the materials are reduced to fine powder and variously mixed to form the paste for the several varieties of these wares. The vitreous ingredients are sometimes calcined to form a frit, which is mixed with the mass. Such mixtures for the tender porcelain are as follows: bone ash 600 parts, kaolin 300, Cornish stone 360, frit 40—the last being composed of 100 parts of bone ash, 90 of sand, and 7 of pearlash. Sometimes, as in the case of table ware, all the ingredients are mixed without calcining, in the following proportions: bone ash 450, Cornish stone 200, kaolin 160, blue clay 45. Articles of such composition, after having been once fired for about 48 hours at a very high temperature, are converted into a porous biscuit, which for most purposes requires an exterior glaze to render the ware impervious to liquids. A variety of preparations are in use for this purpose, mixtures of some of the following ingredients: silex, feldspar, gypsum, carbonate of lime, borax, boracic acid, common salt, potash, soda, and oxide of lead. Colors are given by the addition of the oxides of manganese, cobalt, iron, copper, chromium, &c.; while opaque glazes or enamels are formed by introducing oxide of tin or phosphate of lime. The glaze made into a paste is applied upon the surface of the biscuit, and this is reheated at a less temperature (in England) and for a shorter period than in the first firing. The following analyses from Knapp's "Chemical Technology" represent the composition of some of the clays deprived of water and porcelains:

Clays and wares.	Silica.	Alumina.	Protoxide of iron.	Lime.	Magnesia.	Phosphate of lime and protoxide of iron.	Alkali and loss.	Specific gravity.

—The mixtures for true porcelain are much more simple than those for the soft porcelain. They consist chiefly of kaolin and ground feldspar, the proportions varying in the same establishment with the varying composition of the kaolin, which is a natural mixture of decomposed feldspar with particles of the same mineral undecomposed and also of quartz, all which by grinding and mixing are thoroughly incorporated together. A little carbonate of lime is also introduced. The mixture should give as near as may be the proportions of the Paris ware in the foregoing table, and this at one time may be presented by the following quantities:

Materials.	Parts.	Constituents.			
		Silica.	Alumina.	Lime.	Potash.
Kaolin	48	30.00	16.90	0.05	0.96
Feldspathic sand	48	28.30	17.04	0.58	2.01
Lime	4	..	..	4.00	..
Total	100	58.30	33.94	4.58	2.97

It is remarkable that mixtures of the pure materials in these and similar proportions fail entirely to produce the porcelain structure. This is attainable only by the use of the natural mineral compounds. The glaze is also feldspar, to which a little gypsum is sometimes added, but no metallic oxide. It is slightly more fusible than the mass, and being of the same nature with it a thorough adhesion of the two readily takes place, and no liability is incurred of the splitting into a fine network of cracks, known as crazing, which is not unusual with the glazes of other wares. This glaze is also much harder and wears better than those containing lead.—Some of the mixtures for white fine stoneware may be as follows, the first series being adapted for jugs, pitchers, &c., and the second for Wedgwood mortars:

Materials.	I.	II.	III.	IV.	I.	II.	III.	IV.
Cornish stone	80	40	100	80	200	90	50	50
Kaolin	20	10	20	10	..	80	20	40
Blue clay	40	20	18	18	60	80	25	20
Flint	20	..	40	2	..	..	..	..
Glass	..	..	..	..	..	..	1	..

When it is desirable to glaze these wares, the effect is produced by "smearing" over the inside of the seggars a wash of certain mixtures of salt, nitre, oxide of lead, &c., in hot water, as flint powder 10 parts, bone ash 5, nitre 3, salt 5; or lead 6, Cornish stone 3, salt 3. Volatile portions of these, as the salt and lead, combine in part with the silica of the mass, and thus a thin glaze is laid over the surface of the ware. The composition of several varieties of stoneware in 100 parts is seen in the following table:

	Locality.	Silica.	Alumina.	Ox. iron.	Lime.	Magnesia.	Alkali.	Loss.	Description.
Glazed.	St. Amand....	75.00	22.10	1.00	0.25	trace	0.84	0.31	Common body of earthy glaze.

	Japan	62.04	20.30	15.58	1.08	trace	traco	1.00	Very fine body, well moulded, deep brown red color.
	China	62.00	22.00	14.00	0.50	trace	1.00	0.50	Do. do.

For fine earthenware a great diversity exists in the proportions of the ingredients employed. Some of the mixtures are as follows:

Materials.	Ironstone china bodies.			Turquoise body.	Fine earthenware bodies.		
Cornish stone.....	130	200	70	60	75	300	200
Kaolin............	120	150	50	175	200	300	650
Blue clay.........	60	100	30	300	200	500	500
Flint.............	30	120	25	200	200	300	450
Turquoise stain...	..	..	..	20	..	..	..

The turquoise stain consists of 1 lb. blue cobalt, 2¼ lbs. flint, and 10 lbs. oxide of zinc, calcined together and finely ground. Numerous receipts are given of colored clay mixtures for ornamentation.—The preparation of the crude materials for shaping into articles of pottery is a work of no little labor and time. The manner of collecting the kaolin is noticed in the article CLAY. All the other materials are ground to very fine powder, and are then mixed by stirring them with water in large cisterns. The surplus water is afterward removed from what is now called the slip by various methods. It is absorbed by the gypsum bottoms of the boxes into which it is drawn, or pressed out through linen bags, or separated by filtration aided by exhausting the air from below the filter. When reduced to the consistence of dough it is then to be worked over thoroughly by kneading, treading, beating, &c. Porcelain paste especially requires long continued working, and should after this be stored away moist for a year or more to go through the "moulding" process, by which its plasticity is increased. Finally it is worked over by the slapping process, which consists in dashing the lumps into which it is cut by a brass wire against each other and thus incorporating them together. Form is given to the articles either by the potter's wheel, a process known as "throwing," or in moulds by "casting" and "pressing." The potter's wheel has experienced little change since its use in Egypt 2,000 years B. C. It is a flat disk upon an upright axle, turned by a belt from another wheel, by hand, or by the foot of the workman applied to a wheel attached below to its axle. The potter throws upon the centre of the disk a lump of clay cut by the brass wire of the slapper into the exact size of the piece to be made, and as it slowly revolves as in a lathe he shapes it with his hand, hollowing out a cavity for the interior of the vessel and giving to the exterior its true outline. When the cavity is too small to admit the hand, he uses some simple tool, as a wet sponge attached to a crooked stick, and for the outside when exactness of form is required a piece of metal having the profile of the intended article. Some articles roughly formed at first are allowed to dry partially before the shaping is completed. Moulds are made of gypsum, which partially absorbs the moisture in the paste. They are single for the simpler forms, shaping but one surface; others are double for giving the shape to both surfaces; and others are in several parts for moulding complicated forms, which, made separately, are afterward united together. The thin slip or paste is prepared for the mould in a sheet either by "throwing" or by rolling, after the manner of rolling dough; and if for a plate, it is laid over and pressed down with a wet sponge upon the mould for forming its inner surface, which mould is set upon a revolving disk, and as this carries the sheet round the surface is shaped by a metallic profile of the intended shape brought in contact with the paste. The manipulations of this sort are greatly varied according to the work in hand. Handles, spouts, and the ornamental pieces are separately moulded and then attached by means of slip. After being moulded the vessels require a careful revision, usually on the potter's wheel, in which all roughness and excess of paste is removed, and sometimes an ornamental surface produced by a delicate sort of carving with the knife. The effect of lace upon the drapery of figures is very ingeniously obtained by attaching to the paste real lace dipped in slip, which is afterward destroyed in the firing. In the drying distortion is very apt to occur from the moisture not going off uniformly, thus causing unequal shrinkage. Great pains are taken to guard against this, and the pieces are put upon shelves and very slowly dried, away from the direct rays of the sun and from artificial heat. The application of glaze to porcelain biscuit (that is, after a preparatory firing) is made by dipping the vessels into tubs containing the glaze composition in slip suspended in water.

The dipping is done as quickly as possible, and the composition is then brushed off from those parts which would come in contact with the support upon which the pieces are to rest. The firing is conducted in tall cylindrical kilns, like glass furnaces, into which the flames pass through flues from outside fireplaces. The articles to be baked are carefully placed in drum-shaped clay vessels, called seggars, which when filled are piled upon each other, forming columns that fill the kilns. These must necessarily be capable of withstanding greater heat than that required for the articles they contain, and upon the possibility of producing such vessels at moderate cost the success of the porcelain manufacture in any locality is chiefly dependent. The time required for the firing varies in different places and for different wares, but for French porcelain it is usually from 25 to 30 hours. When this is completed the kiln is closed up and left from 5 to 8 days for the ware to anneal. When it is removed a portion, sometimes amounting to $\frac{1}{4}$, is found to be misshapen and ruined, and all the pieces require a final revision and dressing with a stone, grinding wheel, &c.—The pigments used for painting porcelain consist of a flux with a coloring ingredient, which is commonly a metallic oxide. Those colors which withstand the high heat of the kiln are termed refractory colors, and are applied before glazing. The others, termed muffle colors, from the kind of furnace in which they are burned in, are applied after the baking, and therefore involve an additional process; and as the tint of some of them varies with the temperature, this is carefully watched and regulated. Gold is applied in its precipitate mixed with $\frac{1}{15}$ its weight of oxide of bismuth, and rubbed up with thickened oil of turpentine. This is applied with a brush, and after firing the gilding is brought out by burnishing.—The variety of porcelain biscuit called Parian or Carrara ware was introduced about the year 1845 in England, and has since been employed as a beautiful material for statuettes, which resemble the marble itself. It differs from porcelain chiefly in the use of a feldspar more fusible than the Cornish stone. Its application to the production of models has engaged the attention of eminent sculptors and potters in England, and exquisite small works of art are now cheaply furnished in it. The work, however, requires great care and skill, the figures being cast in different parts, which are afterward united together. A very thin slip is poured into the mould, and a considerable time is allowed for it to harden before it is removed. The parts not well supported are kept in place by props until the mass has acquired sufficient consistence.—In Europe the forming of collections of pottery has been an object of interest not only to numerous wealthy amateurs, but also to the governments of states. In England more than 100 such collections are noticed by Joseph Marryat, several of which are limited to a special variety of ware alone. In Dresden is the national collection of the Japanese palace founded by the elector Frederic Augustus I. In this collection the oriental china alone occupies 18 large rooms. The progress of the Dresden manufacture is represented by a great variety of well selected pieces. The museum of the porcelain works at Sèvres was arranged by M. Alexandre Brongniart, commencing in 1812, for the purpose of illustrating the progress of the ceramic art from the manufacture of the rudest ware to that of the finest porcelain, and also the geography and chronology of the art. The collection is eminently of a practical character, made up of illustrative specimens alone not merely of the finished works, but of the materials used in the manufacture in all parts of the world. Each one of these, to entitle it to a place in the collection, must be provided with a label describing its character, locality, date, use, &c. This manufacture affords an eminent instance of the value imparted to worthless materials by skill and science. Single vases of Sèvres china 12 to 15 inches high have repeatedly sold for $5,000, Majolica plates for $600, Chinese kylins or antique vases for $1,500, &c.; and the market is constantly rising, as with every improvement in the modern art choice antique specimens are more eagerly sought.—The principal works on pottery are: A. Brongniart, *Traité des arts céramiques ou des poteries considérées dans leur histoire, leur pratique, et leur théorie* (Paris, 1844); A. Brongniart and D. Riocreux, *Description méthodique du musée céramique de la manufacture royale de porcelaine de Sèvres* (Paris, 1845); Joseph Marryat, "A History of Pottery and Porcelain, Mediæval and Modern" (2d ed., London, 1857); Samuel Birch, F.S.A., "History of Ancient Pottery" (London, 1858); and Knapp's "Chemical Technology."

POTTO (*cercoleptes*, Illig.), a genus of carnivorous mammals, of small size, inhabiting tropical America. They resemble the bears in their plantigrade movements and in their dentition, but differ in other characters; they seem to form the connecting link between the quadrumana and the plantigrade carnivora. The molars are $\frac{5-5}{5-5}$, small, the anterior 2 conical, and the others tuberculate with flat crowns, canines short and blunt; muzzle short and rounded; the eyes large; the tongue slender, long, and extensile; tail long, hairy, and prehensile; feet plantigrade, but the 5 toes are separate, capable of independent motion, and provided with sharp claws; legs short; fur woolly. The common potto, sometimes called kinkajou (*C. caudivolvulus*, Illig.), is about the size of a cat, but more slender, of a general yellowish brown color, sometimes reddish brown; in form and habits it resembles the lemurs, and is nocturnal, an excellent climber, using the fore paws like the squirrels to convey food to the mouth; it is omnivorous, feeding on fruits, honey, insects, eggs, and small birds and mammals, like other plantigrades; it is fond of plundering the nests of wild bees, obtaining the honey by means of its long tongue, whence it has received the name of honey bear; it is a native of Guiana, New Granada, Peru, and some of the West India islands. Being gentle and playful in disposition, it is often tamed as a pet, and is not uncommonly seen in menageries.—Potto is also the native name of an African lemur. (See Lori.)

POTTSVILLE, a village of Norwegian township, and capital of Schuylkill co., Penn., on the Schuylkill river at the entrance of Norwegian creek; pop. in 1860, 9,454. It is the terminus of the Philadelphia and Reading railroad, by which it is 93 m. N. W. from the former and 35 m. from the latter. The village is situated near Sharp mountain, on a very uneven surface, in the midst of an extensive coal region, from which its chief source of prosperity is derived. It contains, beside the county offices, 4 founderies and machine shops, a brass foundery, an iron safe manufactory, a steam factory of sashes and woodwork, 3 English and 3 German weekly newspapers, a Welsh monthly magazine, and 16 churches, viz.: 1 Baptist, 2 Episcopal, 1 Evangelical, 1 German Reformed, 3 Lutheran, 1 Methodist, 2 Presbyterian, 2 Roman Catholic, and 3 Welsh.

POUCHED RAT. See Gopher.

POUCHET, Félix Archimède, a French physician, born in Rouen, Aug. 26, 1800. He studied medicine in his native city, and subsequently in Paris, where he was admitted to practice in 1817. Upon his return to Rouen he was named professor of natural history in the museum just founded there, and in 1838 professor in the Rouen medical school. He has written *Zoologie classique, ou histoire naturelle du règne animal* (2 vols. 8vo., Rouen, 1841); *Recherches sur l'anatomie et la physiologie des mollusques* (4to., 1842); *Théorie positive de l'ovulation spontanée et de la fécondation des mammifères et de l'espèce humaine* (8vo., 1847), and other works.

POUGHKEEPSIE (said to be from Ind. *Apo-keep-sink*, pleasant harbor), a city and the capital of Dutchess co., N. Y., on the E. bank of the Hudson river and on the Hudson river railroad, 75 m. N. from New York and 69 m. S. from Albany; pop. in 1860, 15,000. The greater portion is built on a table land, from 150 to 200 feet above the river. About a mile back is a hill, 500 feet above the river, on which is the Poughkeepsie collegiate school. From this eminence the eye has a range of about 2,500 sq. m. The city is regularly laid out, and has good public buildings and many elegant private residences. It contains a city hall, 4 banks, a savings bank, an academy, 6 public schools with 1,900 pupils, a law school, lyceum, and orphan asylum and home for the friendless. It has a public library containing about 6,000 volumes. A rural cemetery of 54 acres has been laid out a short distance below the city. There are a number of manufactories, the principal of which are the Poughkeepsie iron works, with a capital of $200,000; a carriage factory, capital $35,000; carpet factory, $60,000; chair factory, $60,000; and M. Vassar and co.'s brewery, capital $150,000, which makes 30,000 bbls. of ale per annum. There are 21 churches, viz.: 2 Baptist, 1 Congregational, 3 Episcopal, 1 Friends', 1 Jewish, 1 Lutheran, 5 Methodist, 1 Presbyterian, 2 Reformed Dutch, 2 Roman Catholic, and 1 Universalist. On June 4, 1861, ground was broken for the foundation of the Vassar female college, for the erection and endowment of which Matthew Vassar, Esq., of Poughkeepsie, has given $400,000. It is incorporated by a charter granted by the legislature in Feb. 1861, and its affairs are in the hands of a board of trustees. It is to be completed in 1863. Steamboats ply between Poughkeepsie and New York, and the New York and Albany steamers touch here; and it is connected by a steam ferry with New Paltz on the opposite side of the river.—Poughkeepsie was originally settled by several Dutch families in 1690–1700. In 1778 the legislature was convened by Gov. Clinton at the Van Kleeck house, a stone building pierced for musketry and used for defence, and among other acts gave its assent to the articles of confederation; and it was here on July 26, 1788, that the national constitution was ratified in the state convention assembled for the purpose of its consideration. Poughkeepsie received a city charter in 1854.

POUILLET, Claude Servais Mathias, a French physicist, born at Cuzance, department of Doubs, Feb. 16, 1791. He was educated at the normal school, was successively a professor there, at the Bourbon college, the polytechnic school, and the Sorbonne, was preceptor to the sons of Louis Philippe, and finally director of the *conservatoire des arts et métiers*. He was also an opposition member of the chamber of deputies, and opposed the *coup d'état* of Louis Napoleon. He has written extensively on physics and electricity.

POUJOULAT, Jean Joseph François, a French author, born at La Fare, department of Bouches-du-Rhône, Jan. 26, 1808. Having been educated at the college of Aix, he went to Paris in 1826, and became acquainted with M. Michaud, whom he assisted in preparing his *Bibliothèque des croisades*, and in 1830 accompanied him on a tour through the East, an account of which they published in their *Correspondance d'Orient* (7 vols., Paris, 1833–'5). He subsequently edited with Michaud the *Nouvelle collection des mémoires pour servir à l'histoire de France depuis le* 13e *siècle jusqu'à la fin du* 18e (32 vols. 8vo., 1836–'9), and has since published many works upon historical and literary subjects.

POUND (Lat. *pondus*, a weight), a measure of weight. As mentioned under Avoirdupois, two different pounds are in use. One is called the avoirdupois or commercial pound, and is equal to 7,000 grains; and the other the apothecaries' or troy pound, of 5,760 grains. (See Avoirdupois.)

POUND (Anglo-Sax. *pund*, a fold), in law, en, pinfold, or enclosure of any kind au-orized by law and belonging to a town, y, or county, in which horses, asses, mules, ep, goats, and swine that are wandering ray, or are trespassing, may be confined until emed and taken out by the owner, by due ocess of law or in a lawful way. The prac-e of impounding stray or mischievous cat- is extremely ancient in England, and was opted by the American colonies from their ginning. The whole process is carefully gulated by statutes in the United States. he provisions of these statutes differ very uch. Perhaps the most important of the evailing principles of law on this subject sting however on authority rather than upon atutes) is, that a pound keeper is bound to ceive every animal offered to his custody in e form of law, and is not amenable whether he animal be pounded for legal and sufficient use or otherwise.

POUND STERLING, a denomination of oney, originating from the pound weight of lver, which anciently was divided into 240 ces called pence. These pence were desig-ated *esterling*, whence the name "sterling," the gal description of the English current coin. his is supposed to have been derived origi-ally from Easterlings, the popular name of aders from the Baltic and from Germany, who visited London in the middle ages, and some of whom were probably employed in coining. The pound sterling is a money of ac-count; the gold coin representing it is called a sovereign, whose current value in U. S. money is $4.86, and its actual value slightly more.

POUNDS, John, an English philanthropist, born in Portsmouth in 1766, died there, Jan. 1, 1839. Being crippled by an accident in his youth, while working in the royal dockyard at his native place, he took up the occupation of a cobbler. At the age of 22 he undertook to support a child of his brother's, who was a cripple from inversion of the feet. After many efforts he succeeded in restoring the child's limbs to their true position, and commenced teaching him to read. Thinking that he would learn faster if he had companions, he invited a poor neighbor to send his children to his shop for instruction, and in a few months extended the invitation to other families, till his shop, 6 by 18 feet, was filled with scholars. These, by processes of his own contrivance, which bore a strong resemblance to Pestalozzi's, though he had never heard of that celebrated educator, he instructed in the rudimentary branches, and under his tuition they gained as thorough a mastery of them as the children in the best public schools. There were always many more applicants for admission into his school than his little shop would hold; but when there was a vacancy he always selected the most turbulent and vicious children, and seldom failed to make them quiet and well behaved. Without any pecuniary assistance from others, and amid great poverty and privations, he maintained this "ragged school" to the very day of his death, a period of nearly 50 years. His school, though a little later than that of Tata Giovanni (see *Borgi, Giovanni*), was prompted by the same motives, and was, at least in Great Britain, the beginning of "ragged schools," since so extensively established in the United Kingdom and elsewhere.

POUSSIN. I. Nicolas, a French painter, born in Andelys, Normandy, in 1594, died in Rome, Nov. 19, 1665. He was descended from an ancient but impoverished family of the French nobility, and was carefully instructed in literature and the sciences under the supervision of his father. He acquired the elements of his art from two French painters of moderate ability, but received his first ideas of style and composition from studying engravings of the works of Raphael and Giulio Romano. The Italian poet Marino, struck by some of his earlier efforts, induced him to visit Rome, where he arrived in 1624, and was presented to Cardinal Barberini. The departure of this prelate from the city and the sudden death of Marino left him, without friend or patron, to struggle for himself, and for several years he earned a bare subsistence by disposing of his pictures for trifling sums. At this time he lived with the sculptor François du Quesnoy, and under the influence of this association, as well as of the tastes with which his classical training had imbued him, he made close studies of the most celebrated antique statues and bass-reliefs. He also profited much by the pictures of Raphael and Domenichino, but his style was founded mainly on the antique; and so engrossing were his studies of the ancient statues that, as Sir Joshua Reynolds has observed, "he may be said to have been better acquainted with them than with the people who were about him." Fuseli, in allusion to his enthusiasm for the antique, said that "he painted basso-rilievo." His "Death of Germanicus" and "Capture of Jerusalem by Titus," painted for Cardinal Barberini, first brought him into notice, and in 1639 his reputation was so well established that Louis XIII. sent him a special invitation to France, made him his first painter in ordinary, with a pension, and lodged him in the Tuileries. The jealousy of Simon Vouet and other rival artists rendered his life uncomfortable, and in 1642 he gladly availed himself of an opportunity to return to the more congenial atmosphere of Rome, promising however to revisit Paris. The death of Louis and of Richelieu in the succeeding year afforded him an excuse for refusing to fulfil his engagement, and the remainder of his life was passed in Rome. He lived quietly and unostentatiously, absorbed in the practice of his art, and produced subsequent to his return from France many easel pictures of large size, which he readily disposed of at moderate prices. So liberal was his disposition, that notwithstanding his frugal life he left at his death a property amounting to only 15,000 Roman scudi. As a painter of history, classical mythology, or allegory, and of landscape, Poussin was one of the most remarkable and learned of his age; and his works, which are widely dispersed among public and private galleries, are still held in great esteem. His historical works, according to Dr. Waagen, represent three distinct periods: the first, comprising his early residence in Rome, being distinguished by hardness of outline, thin coloring, and defective composition; the second, by excellence of composition and expressive heads; and the third, by an imitation of the antique which finally becomes mannered and monotonous. Of his large historical pieces the Louvre contains a noble collection, including the "Deluge;" "Rape of the Sabines;" "Eliezur and Rebecca;" the "Finding of Moses;" "Christ appearing at the Prayer of St. Francis Xavier and healing a Japanese Woman," which Waagen calls the best of all his altarpieces; and "Christ healing the Blind Man of Jericho," according to the same authority, the most satisfactory of his later works. In the same collection are his celebrated *Et in Arcadia Ego*, aptly described as "a noble pastoral in which the mutability of all earthly things is suggested in the finest and most touching manner;" and "Eurydice bitten by the Serpent," conveying a similar moral, and like its companion picture distinguished by its sentiment of repose and its grand and simple landscape. The Louvre also contains the series of "Four Seasons," painted during the last 5 years of his life. In the British national gallery are some of the finest of his purely classical or mythological subjects, one of which, the "Dance of the Bacchanals," reflects so completely the spirit of antique sculpture that it might have been copied from the bass-reliefs of a Grecian urn. But the most celebrated of Poussin's works in England are the two sets of the "Seven Sacraments" in Belvoir castle and the Bridgewater gallery. In the latter collection is also a fine picture of "Moses striking the Rock," and in that of Mr. Miles at Leigh Court the well known "Plague of Athens." Scattered throughout his works are also pieces from sacred and profane history of much sweetness of tone and expression; "a proof," observes Mrs. Jameson, "that Nicolas Poussin could be, when he chose, a poetical and effective colorist." On the other hand, he could descend to the most revolting treatment of a subject, as in his "Martyrdom of St. Erasmus" in the Vatican, in which the entrails of the saint are in the act of being wound out of his body by a windlass around which they are twisted; a work justifying the remark of Diderot, that if all the martyrdoms painted by great masters should escape the ravages of time, posterity would regard the present race of men as "ferocious beasts or anthropophagi." Notwithstanding his pedantry and faults of style and color, Poussin was, in the estimation of Kugler, "a great man, and his pictures bear characteristics of the highest genius and the most refined taste." As a painter of ideal landscape, according to the same authority, "his conception of nature is serious and solemn; a grandeur of form prevails as in his historical works, while his coloring, which never possesses great charm, is sometimes almost harsh." His landscapes are commonly embellished with ancient architecture or figures taken from classic mythology and history, and present excellent specimens of what is called the "heroic" style of this department of painting. II. Gaspar, brother-in-law of the preceding, born in Rome in 1613, died there in 1675. His family name was Dughet, but after the marriage of Nicolas Poussin with his sister, he was adopted by Nicolas, who had no children, and assumed his name. Under the instruction of his brother-in-law he became very eminent in the department of landscape, depicting the finest scenery in the vicinity of Rome, Tivoli, and Frascati, and, in imitation of his master, composing ideal pictures. He was a rapid and facile painter, firm in his handling, and so careful a student of nature that he gave to every tree and shrub the peculiar character of its species. For aërial effects and chiaroscuro he was almost unrivalled, although his pictures frequently have a sombre tone, which is believed to be the effect of time. In his earlier works he followed the manner of Nicolas, with which he subsequently combined striking peculiarities of his own. His composition, though founded on the heroic style, having a brighter and freer character, which forms a happy contrast to the severe earnestness of his master. He improved his color by studying the works of Claude Lorraine. Kugler says: "It is what may be called the living soul of landscape which first appears with its full effect in Gaspar Poussin's works." His peculiar skill in aërial effects was shown in his land storms, which he executed with remarkable power, and of which a well known example, representing Dido and Æneas taking refuge from the tempest in a cave, is contained in the British national gallery. In the same collection is a landscape entitled "Abraham and Isaac going to the Sacrifice," which has been called the painter's masterpiece.

POWELL, Baden, an English clergyman and author, born in 1796, died in London, June 11, 1860. He was graduated at Oxford in 1817, and in 1827 was elected Savilian professor of geometry in that university, which appointment he held until his death. He was active in his efforts to introduce into the university a greater attention to the natural sciences, and although in holy orders, he held no living. His writings are either strictly scientific in their character, or treat of the connection between science and theology. Among the former may be mentioned a "History of Natural Philosophy" (1834); "A General and Elementary View of the Undulatory Theory of Light" (1841); and a large number of papers in the transactions of various scientific societies, of ch the most remarkable were "Reports on minous Meteors," "On the Repulsive Power Heat," "On the Dispersion of Light," "On etic Polarization of Light," and "On Irra- tion." Of the second class may be mention- "The Connection of Natural and Divine th, or the Study of the Inductive Philoso- considered as subservient to Theology" ndon, 1838); "Essays on the Spirit of the uctive Philosophy, the Unity of Worlds, the Philosophy of Creation" (1855); ristianity without Judaism" (1857); "The der of Nature considered with reference to Claims of Revelation" (1859); and "On Study of the Evidences of Christianity," in ssays and Reviews" (1860). The purpose hese works of the latter class was to maintain the rejection of ideas generally prevalent n theological subjects, which in the prog- of modern science have been called in estion, or at least modified, is in no way a drance to a sincere belief in the cardinal ths of religion.

POWER of a quantity, in mathematics, the ult obtained by multiplying that quantity a rtain number of times by itself. Thus, the power of 2 is $2 \times 2 = 4$; the 3d power, $2 \times 2 = 8$. The degree of the power, or e number of times that the given quantity is ken as a factor, is expressed by a number lled the exponent, written above and at the ght of the quantity; thus, 2^3 denotes the 3d wer of 2, and 2 is styled the root of 2^3.

POWER, TYRONE, an Irish actor and author, rn in county Waterford in 1795, perished at a in 1841. His mother, having been left a dow during his infancy, removed to Glamor- anshire, South Wales, and in the theatre of e neighboring town of Cardiff Tyrone made debut upon the stage as Romeo. For a umber of years subsequent he performed at fferent provincial theatres, attempting both mic and pathetic parts, although the former ere better suited to him. In 1818 he retired om the stage, but in 1821 reappeared at sev- al London theatres. His first decided suc- ess in the metropolis was achieved in 1824 in e part of Paddy O'Halloran, and thenceforth found it to his advantage to devote his abili- es exclusively to the delineation of Irish char- cters, in which he was unrivalled. To a prepos- ssing personal appearance he united a viva- ious air, a genuine appreciation of Irish hu- mor, a rich brogue, and a fine taste for singing. hese qualities made his personation of such arts as the "Irish Tutor," Rory O'More, Mur- ch Delany, "Teddy the Tiler," Sir Patrick Plenipo, Phelim O'Flannigan, and many oth- rs, written expressly for him, among the tri- mphs of the comic stage. In 1833 he visited e United States, where he obtained great suc- ss in his leading parts; and in 1840 he made nother professional tour in North America. e embarked March 11, 1841, for Europe in the steamship President, which was never subse- uently heard of. Power was the author of "Impressions of America" (2 vols. 8vo., London, 1836); "The King's Secret," a novel; "The Lost Heir," &c. He was a man of genial habits, and much amiability and native humor.

POWERS, HIRAM, an American sculptor, born in Woodstock, Vt., July 29, 1805. He was the 8th of a family of 9 children, and passed his youth on his father's farm, acquiring the rudiments of a district school education, and some knowledge of drawing and of various kinds of handicraft. The farm proving unsuccessful, he emigrated with the family to Ohio, and upon the death of his father soon after established himself in Cincinnati, where, after being successively employed in a reading room connected with one of the hotels and in a produce store, he procured a situation with a clockmaker, for whom he collected debts, beside aiding in the mechanical part of the business. About this time he became acquainted with a German sculptor, from whom he learned the art of modelling in plaster, and after a little practice he was able to produce plaster busts of considerable merit. The taste for art fostered by this employment induced him to form a connection with the western museum at Cincinnati, the waxwork department of which was for 7 years under his direction. Aspiring to a higher walk in his profession, and feeling that he might depend for a support upon his labors as a sculptor, he repaired in 1835 to Washington, and was for some time profitably employed in modelling busts of distinguished men. With the proceeds derived from these efforts, and by the assistance of Mr. Nicholas Longworth of Cincinnati, he was enabled in 1837 to carry into effect a long cherished desire to visit Italy. In the same year he established himself in Florence, which, with the exception of occasional visits to Rome and elsewhere, has continued ever since to be his home, and for several months devoted himself chiefly to modelling busts. Gradually gaining confidence in his powers and facility in the use of the chisel, he produced in 1838 an ideal statue of Eve, which excited the admiration of Thorwaldsen, who pronounced it a work which any sculptor might be proud to claim as his masterpiece. A year later he finished the model of his "Greek Slave," his most widely known and popular work, and of which upward of 6 duplicates in marble are in existence, beside an immense number of plaster casts and reduced copies in parian. Among other well known works by him are the "Fisher Boy," of which 3 repetitions in marble have been produced; "Il Penseroso;" "Proserpine," a bust; "California;" "America," modelled for the crystal palace at Sydenham, England; and portrait statues of Washington for the state of Louisiana, and of Calhoun for South Carolina. The latter, his best work of the kind, after suffering shipwreck off the coast of Long Island, was safely deposited in Charleston. Of his busts, which comprise by far the greater part of the productions of his chisel, those of Adams, Jackson, Webster, Calhoun, Chief Justice Marshall, Everett, Van Buren, and other distinguished Americans, are well known and striking specimens. One of his latest productions is a bronze statue of Webster, now erected in the state house grounds at Boston. Mr. Powers is the inventor of a process of modelling in plaster which, by obviating the necessity of taking a clay model of the subject, greatly expedites the labors of the sculptor.

POWERS, Mechanical. See Mechanics.

POWESHIEK, a S. E. co. of Iowa, drained by the North fork of Skunk river, which traverses the S. W. corner, and Beaver, Sugar, and other creeks; area, 576 sq. m.; pop. in 1860, 5,670. It has a fertile soil. The productions in 1859 were 20,470 bushels of wheat, 6,698 of oats, 241,500 of Indian corn, 10,785 of potatoes, 4,096 tons of hay, 4,736 galls. of sorghum molasses, 73,572 lbs. of butter, and 5,266 of wool. Capital, Montezuma.

POWHATAN, a S. E. co. of Va., bordered N. by the James river and S. by the Appomattox; area, about 300 sq. m.; pop. in 1860, 8,391, of whom 5,403 were slaves. It has a level surface and a naturally fertile soil, much of which, however, has been exhausted. The productions in 1850 were 215,155 bushels of Indian corn, 115,437 of wheat, 89,189 of oats, 1,000,490 lbs. of tobacco, and 14,671 of wool. There were 19 churches, and 305 pupils attending schools. Value of real estate in 1856, $1,927,639, showing an increase of 26 per cent. since 1850. Capital, Scottsville.

POWHATAN, a sachem of great authority among the Indian tribes of Virginia at the time of its colonization, died in 1618. He was a man of great native talent, and had raised himself from the rank of a chieftain to the command of 30 tribes, which numbered about 8,000 souls. His dominions included the country between the rivers James and Patuxent, and in the interior as far as the falls of the chief rivers. Of his two places of abode, Powhatan, on the present site of Richmond, was a village of 12 wigwams only; but a guard of 40 warriors constantly attended his person, and his dwelling was watched at night by 4 sentinels. After the extension of his power northward, however, he resided principally at Werowocomoco, on York river, in the present county of Gloucester. He was disposed to look with dislike upon the coming of the whites, though when the first expedition under Newport and Smith visited him at his residence in Powhatan, he treated them with hospitality. Subsequently, Smith having been taken prisoner and about to be despatched by clubs, Powhatan, through the intervention of his daughter Pocahontas, spared his life, and ultimately sent him to Jamestown with strong protestations of regard. During another visit from the English, Powhatan succeeded in overreaching Newport in trade; but an equivalent advantage was obtained by Smith, who exchanged a pound or two of blue beads for 200 or 300 bushels of corn. When Newport subsequently returned to Virginia from England, he was commissioned to discover the South sea; and as he was obliged to pass through Powhatan's territory a number of presents were brought him, one of which was a crown, and the ceremony of coronation was performed a few days later, while in order to have him stoop it was found necessary to lean hard upon the shoulders of the Indian monarch, whose comprehension of the ceremony seems not to have been very clear. For the honor shown him, Powhatan gave Newport his mantle and old shoes. Capt. Smith afterward made an unsuccessful attempt to capture the "emperor" in order to obtain a supply of corn; and in revenge for this, Powhatan prepared to attack the English by night, but was foiled by the watchfulness of Pocahontas. The quarrels between Powhatan and the English did not cease until the marriage of his daughter with Rolfe, after which he was their firm friend.

POWNALL, Thomas, an English statesman and author, born in Lincoln in 1722, died in Bath in 1805. He emigrated to America in 1753, and in 1757 was appointed governor of the colony of Massachusetts Bay. Having been recalled at his own request, he succeeded Sir Francis Bernard as lieutenant-governor of New Jersey in 1760, and soon afterward became governor of South Carolina. In 1761 he returned to England, was made comptroller-general of the expenditures of the army in Germany, and in 1768 was elected to parliament. He earnestly opposed the measures of the government against the colonies. After being [illegible] times returned to parliament, he retired in 1780, and passed the remainder of his life in antiquarian studies. His principal works are: "Description of the Middle States of America" (1776); "A Memorial to the Sovereigns of Europe on the State of Affairs between the Old and the New World" (1781); "A Memorial to the Sovereigns of America" (1783); "Notices and Descriptions of the Antiquities of the Provincia Romana of Gaul" (4to., 1788); "Intellectual Physics;" "Principles of Polity;" "Administration of the Colonies;" and a "Treatise on Old Age."

POZZO DI BORGO, Carlo Andrea, count, a Russian diplomatist, born in Alala in Corsica, March 8, 1768, died in Paris, Feb. 15, 1842. He was descended from a noble but impoverished family, and after receiving an elementary education in his native country completed his studies at Pisa. At the outbreak of the French revolution he was an advocate in Corsica, and intimate with the Bonaparte family. He embraced liberal views, and was sent to Paris with Gen. Gentili to offer to the constituent assembly the thanks of Corsica for having declared that island an integral portion of the territory of France. He was elected to the French legislative assembly in 1791, joined the Girondists, and acted zealously with the war party; but falling under suspicion, he returned to Corsica

er the dissolution of the assembly, attached
mself to the party of Paoli, and when the
and was freed from the dominion of France
came president of the council. When the
glish withdrew he went to London, and there
the agent of the French refugees began his
reer as a diplomatist. He had entirely broken
ith the Bonapartes, and his sympathies were
ogether with the anti-Gallican party. In
98 he went to Vienna in order to bring about
coalition between Austria and Russia against
rance, accompanied Suwaroff in his campaign
1799, and in 1802 entered the Russian ser-
ce as councillor of state. As Russian com-
issioner he was despatched in 1805 to the
ussian, English, and Neapolitan army in the
rth of Italy, was subsequently sent on va-
ous missions to Prussia and Austria, and was
resent in the battle fought off the isle of
enedos, July 1, 1807, between the Russian and
rkish fleets, in which the former was victo-
ous. On account of the treaty concluded be-
een Alexander and Napoleon, Pozzo left the
ussian service in 1808, fearing that he would
delivered over to the latter, and succes-
vely went to Vienna, to Constantinople, and
1810 to London. After the close of the cam-
aign of 1812 he was recalled by the emperor
lexander. His whole influence was constantly
erved to keep Alexander steadfast in the war
gainst France, and the junction of Sweden
ith the allied powers is ascribed mainly to
is representations. In the beginning of 1814
went to England to secure the active co-
peration of that power, strenuously advocated
e bold resolution of marching upon Paris,
d in the congress of Châtillon opposed ac-
ding to the offers of Napoleon. After the
dication of the emperor he was made Rus-
an commissioner to the provisional govern-
ent, attended the congress of Vienna, and
fterward was ambassador at the French court.
e was present at the battle of Waterloo,
here he received a slight wound, and after
e second restoration was offered the post
minister of the interior, but declined it.
e remained in France in the capacity of Rus-
an ambassador, and signed the treaty of Paris
Nov. 1815. In 1823 he was made ambassa-
or extraordinary to Spain, but soon returned,
nd upon the accession of Nicholas to the
rone was created a count. He was ambas-
dor at Paris when the revolution of 1830 broke
ut, and in the following year his situation was
ceedingly unpleasant in consequence of the
ourse pursued by Russia in suppressing the
olish insurrection. So great was the detesta-
on of Russia in Paris, that on the arrival of
he news of the fall of Warsaw in Sept. 1831,
he populace came near storming Pozzo's hotel.
n 1833 he was recalled, but soon sent back.
e was afterward twice sent to London on
usiness relating to the eastern and Belgian
uestions, but after 1835 he retired from pub-
c life on account of his health, and lived in
aris until his death.

POZZUOLANA, a reddish, porous, friable mineral of volcanic origin. When reduced to a fine powder and mixed with lime, it forms a cement of stony hardness. It was discovered by the ancient Romans in the town of Puteoli (now Pozzuoli), and called *pulvis puteolanus.* They made great use of it in their submarine structures, as it hardens as well when immersed in water as when exposed to the air.

PRADIER, Jean Jacques, a French sculptor, born in Geneva in 1792, died in Paris in 1852. He belonged to a family which had left France after the revocation of the edict of Nantes, was sent to Paris while yet a boy, studied under the sculptor Lemot, and received from Napoleon a small pension. He gained a gold medal when 22 years of age, and the next year obtained by his "Philoctetes at Lemnos" the great prize of sculpture, which entitled him to a residence of 4 years in Italy at the expense of the government. At the exhibition of 1819 a gold medal was awarded to him, and in 1827 he was elected a member of the academy of fine arts, to fill the seat left vacant by his master Lemot. Among the most admired of his works are "Psyche," the "Three Graces," "Cyparissus," "Venus and Cupid," "The Bacchante and the Satyr," "Phryne," *La poésie légère* and the two muses which adorn the fountain of Molière in Paris, "Industry" in the Paris exchange, "Liberty" in the chamber of deputies, "Phidias" in the Tuileries garden, and statues of saints in several Paris churches.

PRADON, Jean Nicolas, a French poet, born in Rouen in 1632, died in Paris in Jan. 1698. In 1674 he produced his first tragedy, *Pirame et Thisbé,* which attracted so much attention that when in 1677 Racine produced his *Phèdre,* the duchess of Bouillon and her brother the duke of Nevers, who had a pique against the great poet, caused Pradon to write a tragedy on the same subject under the title of *Phèdre et Hippolyte,* and managed to have it performed at the same time in a rival theatre. The duke and duchess, securing a number of seats in both houses, sent crowds to applaud the play of their *protégé,* while they thinned the ranks of the spectators of Racine. This lasted for 6 nights in succession, and Pradon was apparently the more successful of the two. In order to complete his triumph, he wrote a comedy, *Le jugement d'Apollon sur Phèdre,* a weak attempt to ridicule Racine. Every one of his 11 tragedies is below criticism.

PRADT, Dominique Dufour, abbé de, a French political writer, born at Allanches, Auvergne, April 23, 1759, died March 18, 1837. On the breaking out of the revolution, he was vicar-general of the archbishop of Rouen, was elected by the clergy of Normandy deputy to the states-general, sided with the royalists in the constituent assembly, and in 1791 fled to Hamburg, where in 1798 he published a pamphlet entitled *L'antidote au congrès de Rastadt, ou plan d'un nouvel équilibre Européen.* In another tract, *La Prusse et sa neutralité*

(1800), he urged a coalition of Europe against the French republic. He returned to France in 1801, when his *Trois âges des colonies* (3 vols. 8vo.) appeared. Through the means of his relative Gen. Duroc, he was appointed almoner to the emperor, received the title of baron, and became bishop of Poitiers. In 1808 he accompanied Napoleon to Bayonne, was instrumental in bringing about the abdication of Charles IV. of Spain, and was rewarded by a handsome gratuity and the archbishopric of Mechlin. In 1812 he was appointed minister to the grand duchy of Warsaw; but having failed to fulfil the intentions of the emperor, he was disgraced, deprived of his office of grand almoner, and sent to his diocese. De Pradt even represents Napoleon as saying that but for him he would have made the conquest of the world. On the invasion of France by the combined armies of Europe, he hastened to Paris to join the royalists, and after the battle of Waterloo published his *Histoire de l'ambassade dans le grand duché de Varsovie en* 1812, in which he violently denounced the conduct of the ex-emperor, and which passed through 9 consecutive editions. His zeal for the Bourbons however was received with coolness, and having been obliged to resign his archbishopric, in which he had not been confirmed by the pope, he retired to his estate in Auvergne, and published a number of political works of no permanent importance. In 1827 he was elected to the chamber of deputies by the department of Puy-de-Dôme, but resigned in 1828, and spent the rest of his life in obscurity.

PRAED, Winthrop Mackworth, an English poet, born in London in 1802, died July 15, 1839. He was the son of a prominent lawyer, and was early sent to Eton, where he was joint editor of the "Etonian," a school magazine, in 1820. At Trinity college, Cambridge, he obtained an unprecedented number of prizes for Greek odes and epigrams, and for English poems. During his residence at Cambridge, Charles Knight, the publisher, commenced a magazine of which 3 volumes were published, written by a little clique of poets and essayists, conspicuous among whom were Praed and Thomas Babington Macaulay, then rival leaders in the Cambridge debating society. Praed was graduated in 1825, and called to the bar in 1829. In 1830 and 1831 he was returned to parliament for St. Germain in Cornwall, and soon took a prominent place among the younger conservative members. In 1834 he was appointed secretary of the board of control, and in 1835 he was returned for Great Yarmouth. He was afterward member for Aylesbury, recorder of Barnstaple, and deputy high steward for the university of Cambridge. In 1838 his failing health compelled him to resign his appointments. An edition of his poems was published in New York by R. W. Griswold, and an enlarged one in 2 vols. appeared in 1859. No complete collection of his writings has ever been made.

PRÆNESTE (now *Palestrina*), an ancient city of Latium, situated on a spur of the Apennines, 23 m. E. S. E. from Rome. It was probably older than Rome, although it is first mentioned in history in the list of cities of the Latin league given by Dionysius. Its great power, arising partly from its almost impregnable position, rendered it a place of importance in the early wars of Italy. Originally opposed to Rome, it formed an alliance with that republic in 499 B. C., but a century later became engaged in a war with it. In [illegible] its inhabitants marched to the very gates of Rome, and were routed with great slaughter on the banks of the Allia by T. Quintius Cincinnatus, who, following up his advantage, took 8 towns subject to Præneste, and compelled the city to submit. In 340 Præneste was a conspicuous member of the Latin league against Rome; but the defeat of the combined forces by L. Camillus at Pedum in 338 put an end to the war, and by the terms of the peace which followed the city was deprived of a part of its territory. At the end of the social war the inhabitants received the Roman franchise. During the civil war between Marius and Sulla it was one of the chief places in the hands of the Marian party, and the place of refuge of the younger Marius after his defeat. Sulla captured it after several attempts to bring it relief had failed, massacred the inhabitants, demolished its fortifications, and planted a military colony on its territory. Although not destroyed, Præneste seems never to have recovered from this blow. It became during the existence of the empire a place of summer resort for the Romans, and was also much visited on account of its temple of the goddess Fortune, the seat of a favorite oracle. Its answers were made by the voice of the priestess or by the *sortes Prænestinæ*, characters stamped on dice and drawn from an urn. During the middle ages the place became once more conspicuous as the stronghold of the Colonna family. It was taken by Pope Boniface VIII., who dismantled the fortifications, confiscated the property of the inhabitants, and razed the buildings to the ground. It was rebuilt in 1307, resisted an attack of Rienzi, but in 1436 was captured by Cardinal Vitelleschi, who in 1437 destroyed it. In 1448 it was again rebuilt by the Colonnas. In 1630 it was sold by Francesco Colonna to Carlo Barberini, brother of Urban VIII., for the sum of 775,000 scudi. The modern town of Palestrina is situated principally on the ruins of the temple of Fortune. Among the ruins of the old city many statues and other valuable remains of antiquity have been discovered, and among others the celebrated mosaic, considered the finest of the ancient mosaics now existing. According to Müller it is a natural-historical and ethnographical representation of Egypt.

PRÆTOR (Lat. *præire*, to lead), a Roman officer whose duties were chiefly judicial, and also, according to Cicero, the title given to the nsuls as leaders of the Roman armies. The fice was first created in 366 B. C., when the nsulship was divided between the patricians d plebeians, and it was given to the former as indemnification; it was not held by a ple- ian until 339. It was a kind of third consul- ip, the prætor being called the colleague of consuls, and appointed in the *comitia cen- iata* with the same auspices. When the nsuls were absent from Rome, he exercised ir functions in the city, the senate, and the omitia. He was a curule magistrate, and had e *imperium*, although subject to the consuls, tween whom and himself there was also the fference that he was attended by only 6 lic- rs. Originally the prætor was a consul of e preceding year, and after the admission of ebeians to the office it was filled for some me alternately by the patrician and plebeian nsul of the preceding year. In 246 another gistracy, that of *prætor peregrinus*, was cre- ed with the special duty of deciding dis- tes between foreigners and between citizens d foreigners; and in distinction from him ho filled this office, the other prætor was lled *prætor urbanus*. These two, after elec- n, decided by lot which of the two magis- acies should be filled by each; and if one of em departed from the city at the head of an my, the other discharged his duties. After e extension of the Roman power beyond the nits of Italy and the formation of provinces, ætors were sent to govern them. Thus in 7, Sicily and Sardinia having been subjugat- l, prætors were created for the purpose of gov- ning them; and the same thing happened on e conquest of Spain. Under Sylla the num- r of prætors was raised to 8; under Julius sar successively to 10, to 12, to 14, to 16; der Augustus it varied, but was finally fixed 12; and under Tiberius it rose again to 16. y Claudius two prætors were created for mat- s of *fidei commissa*, but Titus reduced the mber to one; another, however, was created y Nerva with the duty of deciding questions tween the *fiscus* and individuals. At all mes, however, the *prætor urbanus* was the st in position, and was specially spoken of as e prætor. He was the chief magistrate for e administration of justice, and could not be way from Rome for more than 10 days at a me. His duty also was to superintend the di *Apollinares*. He, along with the *prætor regrinus*, had the right of issuing edicts, and ese edicts were one of the sources of Roman w, under the title of *jus honorarium* or *præ- rium*. Under Hadrian these edicts were col- cted and arranged by Salvius Julianus, and titled *edictum perpetuum*; and after the reign that emperor they no longer exercised the ght. They however existed long afterward.

PRÆTORIAN GUARDS. See GUARDS.

PRAGA, a fortified town of Russian Poland, the government of Warsaw, on the right nk of the Vistula, opposite Warsaw, with hich it is connected by a bridge of boats; pop. about 8,000. Here in 1656 the Poles were defeated by Charles Gustavus of Sweden; but the chief interest belonging to the city is connected with the insurrection of 1794. Kosciuszko having been defeated and made prisoner in the battle of Maciejowice, the dispirited and disorganized remnants of the Polish army defended the ramparts of Praga against the victorious Russian forces under Suwaroff. On Nov. 3, 1794, the Russian general ordered an assault, and after a fierce struggle the ramparts were carried, more than 15,000 Polish soldiers being slain, drowned in the Vistula, or taken prisoners, and an almost equal number of unarmed inhabitants of Praga, of every age and sex, brutally massacred. In the evening a great fire arose, which destroyed a large part of the city. After the result Suwaroff wrote from the field of battle to the empress: "Hurrah! Praga! Suwaroff;" and received his promotion in the following answer: "Bravo! field marshal! Catharine."—The vicinity of Praga was the principal seat of the Polish war in 1831.

PRAGMATIC SANCTION (Gr. πρᾶγμα, a deed or act), a state ordinance decreed by the monarch or legislature. The phrase seems to have originated with the Byzantine monarchs, but was early introduced into France, and is now applied to several state decrees which have become historical. I. The ordinance of Louis IX. (St. Louis) in 1260, by which the liberties of the Gallican church were established. II. That of Charles VII. of France, proclaimed at Bourges in 1438, confirming the decrees of the council of Basel, and thereby authorizing the election of bishops by cathedral chapters, &c. It was abandoned by Louis XI., but after his quarrel with the pope it had again the force of law until, in 1516, Francis I. substituted for it his concordat with Leo X. III. The ordinance confirming the decrees of the same council, adopted in Germany in 1439 by the diet of Mentz. It was abandoned in 1448 by the diet in consequence of negotiations with Pope Nicholas V. IV. The instrument by which the Austrian emperor Charles VI., in default of male heirs, endeavored to secure the succession to his heirs of the female line. This ordinance was ratified by the estates of all the kingdoms and principalities of the Austrian empire, and by most of the sovereignties of Europe from 1720. In consequence of this, the archduchess Maria Theresa, wife of Francis of Lorraine, ascended the throne. The attack of Frederic the Great of Prussia on the Austrian province of Silesia, however, was the signal for a violation of the instrument and for a general war throughout Europe. V. The instrument by which Charles III. of Spain, in 1759, settled the right of succession to the throne of the Two Sicilies upon his third son and his descendants.

PRAGUE (Bohem. *Praha*; Germ. *Prag*), the capital of Bohemia, situated on both sides of the river Moldau, 75 m. S. S. E. from Dresden, in lat. 50° 5′ N., long. 14° 25′ E.; pop.

about 145,000. It is overlooked upon all sides by rocky eminences, and surrounded by a wall 12 m. in circumference, which has 8 gates. The city is divided into 5 portions, the Altstadt, Neustadt, Josephstadt, Hradschin, and Kleinseite. On the right or E. bank of the river are the Altstadt, or old town, the principal business quarter; the Neustadt, or new town, which has broad, regular streets, but is inhabited chiefly by the poorer classes; and the Josephstadt, or Judenstadt, the Jews' quarter, a labyrinth of narrow, dirty streets, and low houses. The Jews have magistrates and a town hall of their own, in which they conduct the affairs of their community. On the left bank are the Hradschin, with many edifices of historic interest, and the Kleinseite, which contains the houses of the aristocracy and the ancient Bohemian nobles, with gardens and shrubberies that in many cases extend high up the irregular hills behind. Two bridges span the Moldau within the city, beside the railroad bridge of the Prague and Dresden line. The Carlsbrücke, 1,790 feet long, has 16 arches, and is ornamented on each side with 28 statues of saints. Further up the river is an iron suspension bridge, built in 1841. The most interesting of the public buildings of Prague is the castle of Hradschin, for centuries the residence of the Bohemian kings, and said to contain 440 apartments. It was originally built in 1353 by the emperor Charles IV., but having been destroyed by fire in the 16th century it was rebuilt in the 18th. From a window in this edifice, nearly 80 feet above the ground, two unpopular members of the imperial government were thrown in 1618 by the Bohemian nobles and deputies; this act virtually began the 30 years' war. In the Rathhaus, or town hall, in the Altstadt, portions of which date from 1400, the ancient corporations of Prague held their deliberations and banquets. In the Josephstadt is a Jewish synagogue remarkable for its antiquity, it being believed to be the oldest in Europe. The cathedral, which stands near the Hradschin, finished in 1486, of Gothic architecture, contains the chapel and shrine of St. John Nepomucen, ornamented with about 37 cwt. of silver, and a splendid mausoleum erected by Rudolph II. over the bodies of several Bohemian sovereigns. The Theinkirche in the Altstadt contains the tomb of the astronomer Tycho Brahe. On the highest point of land in Prague stands the Strahow monastery, which has a library of 50,000 volumes. Of the numerous palaces in the Kleinseite, the most remarkable is that of Wallenstein, which, though unfinished, is of immense extent; some apartments with their furniture remain in their original state, and the palace still belongs to a branch of Wallenstein's family. Some of the palaces contain considerable libraries, as the Lobkowitz palace, which has 70,000 volumes, and the Kinsky palace, which has 40,000. The university of Prague was founded in 1348, and at the beginning of the 15th century, it is said, its students numbered 20,000. The original school is now entirely devoted to instruction in medicine, law, and the sciences, and a new one is established for education in theology. Prague has manufactories of printed cotton, linen, silk, and woollen fabrics, jewelry, mathematical and musical instruments, paper, leather, hats, liqueurs, earthenware, &c. Several annual fairs are held.—The date of the origin of Prague is not known, but a portion of it was probably built in the 8th century. It has suffered greatly from the ravages of war, particularly during the Hussite contests. It witnessed the first outbreak of the 30 years' war in 1618, and in 1620 the battle which ruined the fortunes of the elector Frederic was fought near its walls at the foot of the White mountain. In 1631 the city was taken by the elector of Saxony, and the next year was retaken by the imperialists under Wallenstein. The Swedes gained possession of the Kleinseite in 1648, but evacuated it in the same year upon the conclusion of the peace of Westphalia. Prague was taken by the French and Bavarians in 1741. In 1744 it was reduced by Frederic the Great after a severe bombardment, but restored by the peace of Dresden in the next year. The same monarch defeated the Austrians before the city in 1757. In 1848 Prague was the seat of the Slavic congress, and the scene of a national Bohemian outbreak in June, when a desperate contest took place. Windischgrätz, however, gained possession of the Hradschin, and thence bombarded the rest of the city, and by the 19th of June the insurrection was entirely put down.

PRAIRIE. See PLAINS.

PRAIRIE, a central co. of Ark., bounded E. by White river and N. by Cypress bayou, one of its branches, and by bayous Metoe and Des Arc; area, 1,050 sq. m.; pop. in 1860, 8,854, of whom 2,839 were slaves. It has a nearly level surface covered by prairies and forests. The productions in 1854 were 134,295 bushels of Indian corn, 1,455 of oats, and 1,434 bales of cotton. Capital, Brownsville.

PRAIRIE DOG (*cynomys*, Raf.), a genus of American rodents, intermediate between the marmots and the spermophiles or prairie squirrels. The cheek pouches are very rudimentary; the eyes large, and the ears very short; 5 distinct claws on all the feet, those on the fore feet much the largest; the body thick and low, the feet large, and the tail short and thinly haired; the skull short and very broad, with the zygomata strongly convergent anteriorly; molars very large, arranged in curves, strongly divergent anteriorly, and near together behind. The common prairie dog (*C. Ludovicianus*, Ord) is about 13 inches long, with the tail 4 more; the color above is reddish or cinnamon brown, with lighter tips to the hairs and a few black ones intermixed; beneath, brownish white or yellow; tail like the back, with a black tip; in winter the color above is more grayish; the hind soles have a hairy patch. This woodchuck in miniature is abundant on the plains west of the Missouri river, extending as far north as the limits of the United States, and south to lat. 30° N.; it is confined to the prairies, and feeds on plants and occasionally on insects. Prairie dogs live in society, hundreds in the same district, their numerous burrows placed close together, and sometimes extending over a space of miles, meriting the common name of dog towns or villages; around the mouth of the burrows the earth is heaped up to a height of about 18 inches, from the top of which the occupants delight to survey what is going on in the community; their burrows are so deep and extensive, that riding among them is often dangerous to horses' limbs; fond of standing erect at the mouth of their burrow, and rarely going a great distance from it, they retreat in a comical tumbling manner at the least sign of danger, after a short time peeping out, squirrel-like, to ascertain the cause of alarm. They feed chiefly at night, are very shy, and when shot, unless killed outright, almost always manage to get into their holes; they are active, playful, very prolific, and from their habitat as yet not injurious to vegetation; their flesh is tender, fat, and juicy. In the northern districts they hibernate during winter. The prairie dog was probably so named from the sharp tone of its chatter, somewhat resembling the yelp of a small dog, as it bears no resemblance to the dog in external appearance; it is the *petit chien* of the French Canadians and the *wishtonwish* of the western Indians. Burrowing owls and rattlesnakes occupy the burrows with the prairie dogs, both doubtless feeding on the young rodents and occasionally on the half-grown animals; it is probable that they could not master the adults. In regard to the snakes, Mr. Kendall, in his narrative of the Santa Fé expedition, says that the prairie dogs are "compelled to let them pass in and out without molestation—a nuisance, like many in more elevated society, that cannot be got rid of." A smaller species, with a shorter tail, is found on the plains near the Columbia river; this, the *C. Columbianus* (Ord), is of a reddish color above, with the tail edged and tipped with white.

PRAIRIE DU CHIEN, a village and the capital of Crawford co., Wis., on the Mississippi river, 4 m. above the mouth of the Wisconsin; pop. in 1860, 3,000. It is situated on a prairie 9 m. long and 2 m. wide, bordered on the E. by rocky bluffs. There are a number of ancient mounds in the village, and in the vicinity are rich copper mines. It contains 4 churches (Methodist, Congregational, Episcopal, and Roman Catholic), and an academy directed by Dominican nuns. It is the terminus of the Milwaukee and Prairie du Chien railroad, 192 m. in length, and has steamboat communication with St. Paul's and other ports of the Mississippi. Prairie du Chien is one of the oldest towns in the West, having been settled by the French about 1740.

PRAIRIE HEN. See GROUSE, vol. viii. p. 519.

PRAIRIE SQUIRREL, the common name of the North American rodents of the genus *spermophilus* (Cuv.), most of them coming under Brandt's sub-genus *otospermophilus*; they belong to the marmot family, and seem to connect these with the ground squirrels. The ears are moderate but generally distinct, the tail long and squirrel-like, and the cheek pouches well developed; the soles behind the toes are hairy in winter, naked in summer; the claw of the thumb is very small, or is replaced by a flat nail; the body more slender than in the marmot or woodchuck. These animals take the place of the tree squirrels in the West, and are fitted for terrestrial life on the grassy prairies, feeding on the roots and seeds of prairie plants; the body is rather thick-set, and the legs and toes short, with straight nails for digging; they pass the winter in a torpid state in the cold regions, carefully stopping up the mouths of their holes; they are diurnal and gregarious, though to a less extent than the prairie dogs. The California prairie squirrel (*S. Beecheyi*, F. Cuv.) is about 11 inches long, with a tail about 8; the general color above is an indistinct mottling of black, yellowish brown, and brown; below pale yellow; a broad hoary white patch on the sides of neck and shoulders, extending back a short distance on the sides; ears acute and prominent, black on the inside; tail flattened and well covered with hairs; body slender, and the head acute, with long whiskers; fur short, thin, and coarse. This species causes much damage to the farmer in the fields of grain and the vegetable garden, and by disturbing the soil in their excavations. The gray prairie squirrel or gopher (*S. Franklini*, F. Cuv.) is mottled yellowish gray and brown, with a gray head; the length is 9 inches; it inhabits the western states, sometimes annoying the farmer by digging up his newly planted corn and eating the grain as it fills; it is fond of burrowing under drains and ditches. The best known species is the striped prairie squirrel (*S. tridecem-lineatus*, Aud. and Bach.), 6 inches long, with a tail of 4; the color is dark brown above, with 9 stripes of this color alternating with 8 of a yellowish gray (17 in all, the lower ones not always distinct), the 5 central ones of the former with yellowish dots and spots; lower parts and tail brownish yellow, the latter margined and tipped with blackish. It is found abundantly on the western prairies, above lat. 40° N. In Iowa, Wisconsin, Minnesota, and northern Illinois, it is commonly called gopher; for the true animal of this name (*geomys bursarius*, Rich.), see GOPHER. It is not found in heavy timber lands, but sometimes in oak openings, and generally on the prairies; its burrows are so shallow that a few pailfuls of water will commonly drown it out. The food consists of grasses, roots, seeds, insects, and field mice; though it is sometimes destructive in newly cultivated districts or in neglected fields, to an extent which may require a second planting, it probably more than makes up the loss by the destruction of mice and noxious insects; it disappears before the plough, and rarely attacks old and well cultivated fields; it brings forth 6 or 7 young, once a year, in May or June. Its southern representative is the *S. Mexicanus* (Wagn.).

PRAIRIE WOLF. See WOLF.

PRAM, CHRISTIAN HENRIKSEN, a Danish poet, born in Guldbrandsdalen, Sept. 4, 1756, died in the island of St. Thomas, Nov. 25, 1821. He was educated at the university of Copenhagen, and in 1781 was appointed to a situation in the chamber of commerce. About the same time he founded the *Handelstidende* or "Journal of Commerce," with which he was connected for 5 years. He originated the "Minerva," a literary periodical, and in conjunction with some friends established the Scandinavian literary society, of which he was president for a number of years. He held an official appointment in St. Thomas at the time of his death. His principal works are the *Stær-Kodder*, a poem in 15 cantos upon the old Scandinavian legends; and the tragedies "Damon and Pythias" and "Frode and Fingal." A collection of his miscellaneous works was published by Rahbek in 1824–'6, in 4 vols.

PRASLIN, a French marquisate, deriving its name from a village of Champagne, near Bar-sur-Seine, department of Aube, which was in possession of the main branch of the house of Choiseul, but in 1690 came into that of the counts of Chevigny, another branch of the same house, and in 1762 was made a dukedom. I. CÉSAR GABRIEL DE CHOISEUL, duke of Praslin, born in Paris in 1712, died in 1785, succeeded his cousin, the celebrated duke de Choiseul, as ambassador at Vienna, and in 1763 signed the treaty which put an end to the 7 years' war. He was afterward successively minister of foreign affairs and of marine, imparting great energy to naval affairs, and shared his cousin's disgrace in 1770. II. ANTOINE CÉSAR FÉLIX, grandson of the preceding, born in 1776, died in Paris, June 28, 1839, a zealous follower of Napoleon, and chamberlain to the empress Maria Louisa, was made peer during the Hundred Days, struck off the list after the restoration, and reinstated in 1817. III. CHARLES LAURE HUGUES THÉOBALD, son of the preceding, born in 1786, died Aug. 28, 1847. He married in 1825 the daughter of Marshal Sebastiani, who brought with her a large dowry, and bore him 10 children. On Aug. 18, 1847, she was found murdered in her house in the faubourg St. Honoré in Paris. Suspicion fell upon her husband, who had been for several years estranged and partially separated from his wife; he was carried to prison, and there died from taking poison. His guilt was placed beyond all doubt. —The present duke and head of the family is GASTON LOUIS PHILIPPE, born Aug. 7, 1834.

PRATI, GIOVANNI, an Italian poet, born at Dascindo, in the Tyrolese Alps, Jan. 27, 1815. The success of his first poem, *Edmengarda* (Milan, 1841), induced him to relinquish the study of law in which he was then engaged, and devote his time to literature. Having produced several volumes of poems, he published in 184[illegible] a volume entitled "Political Songs," among which the "Hymn to Italy" and the "Song of the Future" became famous in Italy.

PRATINCOLE (*glareola*, Briss.), a genus of wading birds of the plover family, inhabiting the temperate and warmer regions of the old world. About half a dozen species are described in Europe, Asia, Africa, and Australia, frequenting the borders of rivers, lakes, and marshes, in low and in high regions; the food consists of worms and insects, which they pick from the ground or aquatic plants, or take on the wing like swallows; they fly and run very swiftly; the nest is a slight structure on the ground among the thick herbage of the marshes, and the eggs 3 or 4 in number. The collared pratincole (*G. pratincola*, Pall.) is about the size of a blackbird, 9 inches long; it is brown above, white on the rump and below; the throat surrounded by a black circle; the base of the bill and the feet reddish. It is plentiful in Austria, and has received one of its specific names (*Austriaca*) from that country; it is occasionally found in England, and is extensively distributed over the old world; it is usually seen in flocks, which are very noisy; the food consists chiefly of beetles and grasshoppers. It so resembles the swallows in its forked tail and flight, that it was at first placed among them by Linnæus; from its appearance and habits on the ground it is called sea partridge by the French, though rarely found near the coast. The cream-colored pratincole (*G. lactea*, Temm.) is a smaller species, living on the banks of the Ganges; its color above and on the wings is cinereous white, below white; quills and under wing coverts black; tail feathers, except the outer ones, with a black spot. The Australian pratincole (*G. Isabella*, Vieill.) has the breast and upper parts light rufous; throat and upper tail coverts white; abdomen bright chestnut; quills and under wing coverts black; it has a stouter bill and longer legs than the other species, and approaches the coursers (*cursorius*, Lath.).

PRATT, CHARLES. See CAMDEN, EARL.

PRAWN, a marine decapod crustacean, of the macrourous division and genus *palæmon* (Fabr.). About 20 species are described, mostly of small size, though some from tropical regions are a foot long; they somewhat resemble the crawfishes in appearance, habits, and movements. The carapace is broad, prolonged anteriorly into an acute, laterally flattened rostrum, with 8 or 9 teeth above and 3 or 4 below, usually extending beyond the peduncles of the antennæ; the eyes large and prominent; the 1st and 2d pairs of feet terminate in 2-fingered claws, the 2d pair the largest and longest; carpus inarticulate; external jaw-feet short and slender; external antennæ very long, with a scale at the base, and sometimes with 3 threads; 5 pairs of fin-like fringed feet under the tail; the principal swimming organs in forward locomotion; tail ending in movable leaflets as in the lobster, by which the animal darts rapidly backward when alarmed. The best known, most common, and most esteemed as food, is the serrated prawn (*P. serratus*, Leach), found on the coasts of England and France, in rocky situations, and in still, clear water, living among the floating sea weeds; it is about 4 inches long, of a bright gray color, spotted and lined with darker purplish gray; it turns red by boiling. It is taken in traps resembling lobster pots, but of smaller size and closer meshes, and in bag nets. The flesh is tender, sweet, nutritious, and easily digested; it is generally cooked in vinegar and salt; on account of the thinness of the shell the whole animal is eaten; large numbers are consumed, and the London market is supplied principally from the isle of Wight and the Hampshire coast; the females in spring, when with eggs, are most highly esteemed; they are also used as bait; they must be cooked very soon, as the flesh decomposes quickly, and with an almost insupportable odor. Very many are devoured by fishes, but their numbers are kept undiminished by their remarkable fecundity. They are rapid swimmers when alarmed. There are other species in the Mediterranean, the largest of which are salted, and are consumed by the Greeks and Armenians during Lent, with the allied genus *penæus* (Fabr.). The American prawn (*P. vulgaris*, Say) is much like the *P. squilla* (Fabr.) of Europe; it is a little larger than the shrimp, about 1½ inches long, and may be known by the large, upturned, toothed rostrum; the fingers of the 2d pair of feet are shorter than the hand. Larger species are the *P. forceps* (M. Edw.), from Rio Janeiro, 5 inches long; *P. ornatus* (Oliv.), from the Indian archipelago, 6 inches; *P. Jamaicensis* (Oliv.), from the West Indies, 10 to 12 inches; and *P. carcinus* (Fabr.), from the Indian seas, about a foot.

PRAXITELES, a Greek sculptor, who lived in the latter half of the 4th century B. C. Nothing is known of his personal history, except that he was a resident of Athens. He ranks at the head of the later Attic school. Without any attempt at the sublime impersonations of deity by which Phidias had become famous, he was unsurpassed in the exhibition of the softer beauties of the human form. In the Cnidian Venus, his most celebrated work, of Parian marble, modelled from the courtesan Phryne, he expressed perfectly the idea of sensual charms. The position of the left hand was the same as in the Venus de' Medici; the right hand held some drapery which fell over a vase beside the statue, and was intended to indicate that she had just left the bath. Pliny recounts that Praxiteles made two statues of Venus, the one draped, the other naked, and that he thought them of equal value, and offered them for the same price; that the people of Cos bought the draped one, the people of Cnidus the other; and that this latter totally eclipsed the fame of the draped statue. So highly did the Cnidians themselves esteem it, that when King Nicomedes offered them as the price of it to pay off the whole of their heavy public debt, they preferred not to part with a work which gave their city its chief renown. The statue was afterward taken to Constantinople, where it perished by fire in the reign of Justinian. Praxiteles also made two marble statues of Eros. It is said that in his fondness for Phryne, the artist had promised to give her whichever of his works she chose, but would not tell her which of them he thought the best. To discover this she sent a slave to tell him that a fire had broken out in his house, and that his works would perish, whereupon he cried out that all his toil was lost if the fire had touched his satyr or his Eros. The words were reported to Phryne, who chose the Eros, and dedicated it at Thespiæ. It was of Pentelic marble, with the wings gilt, and represented the god in the flower of youth. The satyr is said to have stood alone in the street of the tripods at Athens, and it is supposed that several marble statues, which represent a satyr leaning against the trunk of a tree, are copies of it. The best specimen of these is in the Capitoline museum at Rome. The marble statues of Praxiteles are thought to have been covered with a thin encaustic varnish of flesh color.

PREBEND (Lat. *præbenda*), in the church of England, a sum set apart from the revenue of a cathedral church for the support of a clergyman called a prebendary, on the condition of his officiating occasionally therein. By the act 3 and 4 Victoria, all prebendaries are henceforth styled canons, "honorary," who have no emolument, and "resident," who receive a stipend, and the number attached to each cathedral is defined.

PREBLE, a S. W. co. of Ohio, bordering on Ind., and drained by Franklin, Four Mile, and St. Clair creeks, tributaries of the Great Miami; area, 432 sq. m.; pop. in 1860, 21,820. It has a nearly level surface and very fertile soil. The productions in 1850 were 1,175,391 bushels of Indian corn, 238,435 of wheat, 181,926 of oats, 10,221 tons of hay, and 72,121 lbs. of wool. There were 18 grist mills, 24 saw mills, 4 woollen factories, 8 tanneries, 2 newspapers, 51 churches, and 5,120 pupils attending public schools. It is intersected by the Dayton and western, and the Cincinnati, Eaton, and Richmond railroads. Capital, Eaton.

PREBLE, EDWARD, an officer of the U. S. navy, born at Falmouth neck, the site of the present city of Portland, Me., Aug. 15, 1761, died in Portland, Aug. 25, 1807. His father, Jedidiah Preble, served under Wolfe, was wounded at the capture of Quebec, subsequently held a commission as brigadier-general from the provincial congress of Massachusetts, and was a representative and senator in congress (1780) and judge of the court of common pleas. Edward entered the provincial marine of Massachusetts as a midshipman in 1779, was in the action between the Protector, 26 guns, and the English privateer General Duff, which blew up after a severe combat, was afterward captured off the Penobscot, and became a prisoner on board the prison ship Jersey in the harbor of New York. On being liberated he joined the Massachusetts vessel of war Winthrop, Captain George Little, and distinguished himself by boarding, with 14 men, an English armed brig lying at anchor off Castine, and carrying her out under fire of an English battery. He received the commission of lieutenant in the U. S. navy in 1799, and took command of the Pickering, one of Commodore John Barry's squadron stationed among the Windward islands. At the close of 1799 he was promoted to be captain, the intermediate rank of master commandant being passed over, and appointed to command the Essex, 32, in which he went out to Batavia, and convoyed home a fleet of 14 merchant vessels. Owing to ill health he remained unemployed until 1803, when he received command of the squadron sent against Tripoli. His flagship was the Constitution, 44; and the other vessels of the squadron were the Philadelphia, 38, Capt. Bainbridge; Argus, 16, Lieut. Decatur; Siren, 16, Lieut. Charles Stewart; Enterprise, 12, Lieut. Isaac Hull; Nautilus, 12, Lieut. Richard Somers; and Vixen, 12, Lieut. John Smith. The attention of Preble was first directed toward Morocco, and anchoring at Tangiers with a part of his squadron in Oct. 1803, he opened negotiations by which he finally placed our relations with that power on a friendly footing. On Nov. 12 he gave formal notice of the blockade of Tripoli, off which port he supposed the Philadelphia, the Vixen, and other small vessels then to be. On the 27th he arrived at Malta, where he received letters from Capt. Bainbridge apprising him of the capture of the Philadelphia. At the suggestion of Bainbridge, with whom he kept up a correspondence, the Philadelphia was destroyed at her anchorage in the harbor by Lieut. Decatur (see Decatur, Stephen), Feb. 10, 1804. On July 25 Preble was before Tripoli with 15 sail, including 2 bomb vessels armed each with a 13-inch mortar, and 6 gun boats of 25 tons, built for harbor service, and carrying each a 24-pounder. These gun boats and bomb vessels were borrowed of the Neapolitan government. The first attack was made on Aug. 3 upon the enemy's gun boats, which were anchored in 3 divisions, two of them outside and one inside a line of rocks which forms the harbor, the whole being protected by batteries on shore. About 1 o'clock P. M. Preble stood for the town in the Constitution, his gun boats following in two divisions under Decatur and Somers. As they neared the harbor the Constitution shortened sail and opened a destructive fire upon the batteries, while the gun boats closed with the Tripolitans, carried 3 of the largest by boarding, and sunk 3 others. After a desperate hand-to-hand conflict of more than 3 hours, the smaller vessels of the American squadron took the gun boats, bomb vessels, and prizes in tow, and hauled off under cover of the Constitution's fire. The American loss was but 14 killed and wounded. On the 8th another attack was made, but with less success, as the Tripolitans kept close within the harbor. One of Preble's gun boats was sunk. Another general attack was made on the 28th, when about 3 o'clock A. M. the gun boats, covered by the brigs and schooners and accompanied by all the boats of the squadron, anchored with springs on their cables close to the rocks at the entrance to the harbor. They were in two divisions as before, and as soon as they anchored commenced a fire. As day dawned the Constitution stood in under a heavy fire, and at this time 13 Tripolitan gun boats and galleys were closely engaged with the 8 American boats. As the ammunition of the latter was nearly exhausted, Com. Preble ordered them to retire, and as his frigate came up opened a fire upon the Tripolitan boats, by which one was sunk and two were driven ashore; the rest retreated. The Constitution lay three quarters of an hour within musket shot of the mole, pouring a heavy and destructive fire upon the town batteries, until Com. Preble, finding that all his small vessels were out of gun shot, hauled off. The American vessels were much cut up aloft, but otherwise sustained little injury. A boat of the John Adams (which had joined the squadron on the 8th) was sunk by a shot which killed 3 men. A heavy shot from one of the American gun boats passed through a room in the castle in which Capt. Bainbridge was confined. He was in bed at the moment, and the shot rebounding from the opposite wall fell upon his bed within 6 inches of him. On Sept. 3, a 4th attack was made. The Tripolitans had in the mean time raised and added to their flotilla their boats which had been sunk on Aug. 3 and 28. They also very judiciously changed their mode of fighting, by keeping their boats under way while in action. On this occasion the bomb vessels were directed to throw shells, while the gun boats in two divisions, commanded as before by Decatur and Somers, and covered by the brigs and schooners, attacked the Tripolitan flotilla. Com. Preble brought to in the Constitution very near the rocks, in a position where 70 heavy guns bore upon his ship. Here she opened a very heavy fire, silencing the enemy's batteries in succession. The ship suffered very much, as was to be expected, for she was exposed to more than double her number of guns, generally of heavier caliber, and protected by stone walls. After throwing more than 300 round shot, she hauled off, having by signal previously directed the other vessels to do so. By this time preparations for another species of annoyance, which Com. Preble had meditated for some time, were completed. The Intrepid, a ketch, captured from the enemy, and which Lieut. Decatur had used in destroying the Philadelphia, was converted into a fire ship. In a mall magazine prepared for the purpose 100 barrels of gunpowder in bulk were placed, and on the deck immediately above it were deposited 150 shells, with a large quantity of shot, &c., and a proper train was laid. Capt. Somers commanded the expedition, and Lieut. Wadsworth of the Constitution was second in command, both volunteers. The night of Sept. was selected for the attempt, and the Intrepid stood in, accompanied by several small vessels, which hove to at different stations to pick up the retreating boats. Two of the fastest boats of the squadron, manned by volunteers from the Constitution and Nautilus, had been selected to bring the party off. The wind was light, the night dark and hazy, and the sea perfectly smooth. The Intrepid when last seen was not a musket shot from the mole, and seemed to be still standing in. About this time the batteries opened, and after a few moments of suspense a light like that of a volcano illuminated the harbor, which was followed by a concussion that shook even the vessels in the offing. The transient light of the explosion enabled the fleet to see that the Intrepid had not reached the point at which she aimed. It was now that the return of the adventurers was looked for with the most intense anxiety, but they never reappeared. The vessels on this duty remained off the harbor until the sun rose, but, with the exception of a few fragments here and there upon the rocks, nothing of the Intrepid could be seen. One of the Tripolitan gun boats was missing, and some other damage was supposed to have been done, but on the whole a serious loss was sustained by the Americans without any commensurate damage to the enemy. It was subsequently known, through Capt. Bainbridge, that the bottom of the ketch grounded near the mole, and that some mangled bodies, which could not be identified, were picked up. On Sept. 8 Com. Samuel Barron arrived off Tripoli in the President, 44, with the Constellation, 38, and relieved Com. Preble, who soon after sailed in the John Adams for the United States, where he arrived Feb. 26, 1805. His services were fully appreciated by the country. He received a gold medal from congress, the thanks of which were also bestowed upon him and all the officers and men under his command. A marble monument, executed in Italy, was erected by the officers of the navy in 1806 to the memory of the officers who fell at Tripoli, in the navy yard at Washington, and was afterward transferred to the grounds of the naval school at Annapolis. The health of Com. Preble declined after his return. In 1806 President Jefferson desired to place him at the head of the navy department, but the state of his health did not permit him to accept the position. He was an officer of the highest professional character and conduct, and his influence upon the discipline of the service was lasting and valuable.

PRECESSION OF THE EQUINOXES, a slow regression of the equinoctial points upon the plane of the ecliptic. It is so called from its causing the sun to arrive in either equinox a little earlier than he otherwise would. The effect is to increase the longitudes of the fixed stars at the rate of about 50¼" annually. The discovery of the movement is due to Hipparchus, about 150 B. C. Copernicus was the first to give a true explanation of the phenomenon. Newton discovered its physical cause. This cause is the attraction of the sun, moon, and planets upon the spheroidal figure of the earth, giving to the axis a gyratory or conical motion well represented by the waving or nodding of a top in spinning. The pole of the equator is thus made to shift its place, performing a complete revolution around the pole of the ecliptic in 25,868 years. The value of precession is erroneously given by Ptolemy. The Arabian astronomers reached a result much nearer the true value.

PREËMPTION. See OCCUPANCY.

PREGNANCY. See MEDICAL JURISPRUDENCE, and OBSTETRICS.

PREMONSTRATENSIANS, a religious order in the Roman Catholic church, founded in the diocese of Laon, France, in 1120, by St. Norbert, a canon regular from Xanten, Germany, who afterward (1127) became archbishop of Magdeburg, died in 1134, and was canonized in 1584. On a meadow situated in the forest of Coucy, and pointed out to him, as he believed, from heaven (whence the name of the order, *pré montré*, "the meadow pointed out"), Norbert gathered his first disciples, and gave them the strict rule of St. Augustine. They were at first a congregation of regular canons, and as such were confirmed in 1126 by Pope Honorius II.; but gradually they assumed all the distinctive peculiarities of a monastic community. The order spread with great rapidity; in France it gained great popularity through its efforts for the suppression of the Albigenses, and in Germany it accumulated immense riches, and several of the abbots were raised to the rank of princes of the empire. The abbot of the parent convent of Prémontré, near Coucy, had the title of general, and he formed with three other French abbots the supreme council of the order. From time to time he called together the superiors of all the houses for a general chapter. A female branch of the order was established simultaneously with that of monks, and, as in several other orders founded at that time, the female convents were at first contiguous to those of the monks, and only separated from them by a wall. Later, however, this arrangement was given up. At the time of the reformation the order had about 2,000 convents, of which about 500 were for women. As the great majority of the convents were in England, Scotland, Ireland, Germany, Denmark, Sweden, and Norway, the order suffered great losses in consequence of the success of the reformation. The strictness of the primitive rule having been abandoned, reformed congregations "of the strict obserance" were established in Spain (1578) and in France, which remained however in connection with the other convents, and the union was strengthened by new statutes in 1630. In the 18th century the number of convents greatly decreased, and the female branch became almost entirely extinct. In 1860 the order had 8 convents in Germany (that at Prague being now regarded as the chief convent of the order), 11 in Hungary, 2 in France, 4 in Belgium and Holland, 1 in the United States (at Sac Prairie, Wisconsin), and 1 in Cape Colony, South Africa. The female branch, in the same year, numbered 5 convents in Poland, Switzerland, and Holland.

PRENTICE, George Denison, an American editor, born in Preston, Conn., Dec. 18, 1802. He was educated at Brown university, Providence, R. I., where he was graduated in 1823. He studied law, but did not engage in the practice of the profession, and in 1828 became editor of the "New England Weekly Review" at Hartford, a literary journal, which he conducted for two years. At the end of that time he removed to Louisville, Ky., where in 1831 he became editor of the "Louisville Journal," a position which he still holds, and in which he has won a high and wide-spread reputation for political ability and for wit and satire. For many years the "Journal" was a leading advocate in the West of the policy of the whig party, and at present (June, 1861) maintains with great zeal and ability the cause of the Union against the secessionists. In early life Mr. Prentice wrote several poems, which are to be found in the collections of American poetry, but have not yet been gathered into a volume. A selection has been published from his newspaper paragraphs under the title of "Prenticeana" (New York, 1860).

PRENTISS, Seargent Smith, an American orator, born in Portland, Me., Sept. 30, 1808, died in Natchez, Miss., July 1, 1850. He was the son of a prosperous shipmaster, who during the war of 1812 retired to a farm in the town of Gorham. The son by a violent fever in infancy was deprived for several years of the use of his limbs, and it was not till the age of 10 or 12 that he was able to walk, and then only with a lameness which continued through life. He entered Bowdoin college in the junior class, and was graduated in 1826. He immediately commenced the study of law in the office of Judge Pierce of Gorham; but in the following year, impelled by the wish to seek his fortune in the West, he went to Cincinnati, in which city he remained a few months, and thence proceeded to Natchez, where he supported himself as tutor in a private family while he pursued his legal studies. He was admitted to the bar in 1829, and began practice at Natchez in partnership with Gen. Felix Huston. In 1832 he removed to Vicksburg, where he soon attained a high reputation as an advocate. He was elected in 1835 to the state legislature. In 1837, at the regular November election, he was chosen a representative in congress, but on arriving at Washington found his seat claimed by a member chosen at a special election held in the preceding July for the extra session of congress called in that year by the president's proclamation. In the closely balanced state of parties at that time in the house, a single vote was of great importance, and that fact and the principles involved in the case rendered the "Mississippi election contest" one of unusual interest. The question attracted universal attention in the country. In a speech continued for 3 days Mr. Prentiss argued his claim before the house with an ability and eloquence that gave him at once the highest reputation as a congressional orator. By the casting vote of the speaker the house decided against his admission, and referred the matter back to the people, who at an election in the following April sanctioned his claim by a triumphant majority; and on returning to Washington he took his seat avowedly under the election of November. He took little part in the business or debates of the house, but maintained his reputation as an orator by a speech against the sub-treasury bill. At the end of his term he declined a reëlection, and devoted himself thenceforth to his profession, rarely taking part in politics. In 1840, however, as a whig candidate for presidential elector, he made an active canvass of the state in behalf of Gen. Harrison. He strongly opposed repudiation, and in 1845, partly in dissatisfaction with the course adopted by Mississippi, he removed to New Orleans, where he passed the remainder of his life, going to Natchez in his last illness. Though only 41 years old at the time of his death, Mr. Prentiss already ranked among the most eminent of American orators. "He was distinguished," says Henry Clay in a letter relating to his death, "by a rich, chaste, and boundless imagination, the exhaustless resources of which, in beautiful language and happy illustrations, he brought to the aid of a logical power which he wielded to a very great extent. His voice was fine, softened and I think improved by a slight lisp, which an attentive observer could discern." Mr. Crittenden in a similar letter says: "It was impossible to know him without feeling for him admiration and love. His genius, so rich and rare; his heart, so warm, generous, and magnanimous; and his manner, so graceful and so genial, could not fail to impress these sentiments on all who approached him. Eloquence was part of his nature, and over his private conversations as well as his public speeches, it scattered its sparkling jewels with more than royal profusion."—A "Memoir of S. S. Prentiss" has been edited by his brother (2 vols., New York, 1855).

PREPOSITION (Lat. *præpositum*, placed before), a word expressing a relation between different words, and placed generally before a noun, which in English it governs in the objective case. According to Horne Tooke, all repositions were originally either verbs or ouns. Grammarians generally class them ith relational words, or those which serve nly to denote the bearing of one thing to nother, as "the son of John," and notional ords, which in themselves express ideas. ome of the Greek grammarians enumerated repositions with conjunctions under the comon name of *σύνδεσμος*, or "connective." In reek there are 18 prepositions, in Latin about 0, and in English about 40, not including a umber of particles called inseparable prepoitions, because they are never found singly, s in be-stir, be-speak, &c.

PRESBURG (Hung. *Pozsony*), capital of the ungarian county of the same name, situated n the left bank of the Danube, and on the esth and Vienna railroad, 35 m. E. from the tter city; pop. in 1857, 43,863. It stands on levated ground, and is of semicircular form, ith the river on the S. side. The Danube is ere about ½ mile wide, and is crossed by a loating bridge. The fortifications have been ismantled, but several towers have been rected for the defence of the place. The royal alace, on a height overlooking the town, is of reat historical interest, but was destroyed uring the bombardment by the French in 809, and is now merely a shell. Among the rincipal buildings are the cathedral, the archishop's palace, the Roman Catholic and Calinist colleges, the city hall, a German theatre, nd various private palatial edifices. The prinipal manufactures consist of cotton, woollen, nd silk goods, leather, oil, and tobacco.—Presurg is a place of great antiquity. It became he capital of Hungary when Buda was taken y the Turks, and remained so till Joseph II. gain made Buda the administrative capital in 784. Presburg, however, continued the legislative capital down to 1848, by the laws of which year the seat of the diet was transferred to Pesth. The Hungarian kings of the house of Hapsburg have all been crowned in Presburg, except Joseph II. and Francis Joseph, who preferred to reign without taking the oath of allegiance to the constitution, which precedes the coronation. The hill on the Danube which the kings after their coronation customarily rode up, brandishing their sword in the direction of the 4 cardinal points as a token of their readiness to defend the country against all enemies, is generally visited by travellers. In 1619 Presburg was captured by Bethlen Gabor, prince of Transylvania, but was recaptured by the imperial troops in 1621. After the battle of Austerlitz, the treaty between France and Austria was concluded at Presburg (Dec. 1805). The city was taken by the French in 1809.

PRESBYTERIANISM (Gr. *πρεσβύτερος*, elder), a system of church government by presbyteries or associations of teaching and ruling elders. In the Presbyterian church, the presbytery is the leading judicatory; the whole care of the flock is committed to ministers or teaching elders and ruling elders; all ministers of the word and sacraments are on an equality; ruling elders, as the representatives of the people, form a part of all ecclesiastical bodies, in which they have equal authority with teaching elders; and a series of judicatories, rising one above another, secures to each church the watch and care of its appropriate judicatory, and to the whole body an efficient system of review and control. Though there may be much diversity in the names of the several judicatories, as well as in the minuter details of arrangement, yet any church embodying the above principles is strictly a Presbyterian church.—Presbyterians believe that the representative system of church government, in opposition to that which is conducted by the entire ecclesiastical population, has its germ in the Old Testament; inasmuch as the people of Israel, at various periods of their history, had "wise and able men" set over them, who were styled elders; and especially as this is well known to have been a distinctive feature of the synagogue system up to the time of the Saviour's advent. And as each particular synagogue was governed by a bench of elders, of which the bishop or "angel of the church" was the presiding officer, so the whole Jewish body was reckoned as one. In cases of alleged erroneous judgment, there were always appeals admitted to the "great synagogue" at Jerusalem, where there was an opportunity of having wrong decisions reversed. The first converts to Christianity being all native Jews, who had been accustomed to the exercise of government by benches of elders, it was natural that they should adopt the representative plan in organizing the primitive church. Accordingly, we read in the New Testament of "elders being ordained in every church;" of an important question being referred to a synod made up of "apostles and elders;" of "elders who ruled well, but did not labor in the word and doctrine;" of the "elders of the church being called for to visit and pray over the sick," &c. So also Presbyterians hold that preaching the gospel, "feeding the sheep and the lambs" of Christ, and administering the Christian sacraments, are the highest offices intrusted to Christian ministers; that a plurality of elders was, by divine direction, ordained in every church; that in no instance in the New Testament do we find an organised congregation under the watch and care of a single officer; that bishop and elder are titles given interchangeably to the same persons, showing that the title of bishop in the apostolic age designated the pastor or overseer of a single flock or church. They hold that there is but one commission given to the authorized ministers of the word and sacraments; that the ordaining power is manifestly represented as possessed and exercised by ordinary pastors, and that ordination is performed by "the laying on of the hands of the presbytery;" that there is not a solitary instance recorded in the New Testament of an ordination being performed by a single individual; that even when deacons were set apart to their office, it is evident from the narrative (Acts vi. 1-6) that a plurality laid hands upon them with fasting and prayer. They moreover believe that the whole visible church, whether in Jerusalem or in Antioch, in Philippi or in Ephesus, was regarded as one body, subject to the same authority, and regulated by the same judicial decisions; in illustration of which they refer to the fact that when a question arose which was of common interest to the whole Christian community, it was decided by a synod of the "apostles and elders at Jerusalem," and the decrees of that synod were sent down to "all the churches" to be registered and obeyed. Passing from the New Testament to the earliest records of uninspired antiquity, Presbyterians assert that the system of ecclesiastical government disclosed by the epistles of Ignatius and Clemens Romanus is thoroughly presbyterian; that this system prevailed for more than 100 years after the apostolic age; that the first inroads which were made upon it were by the pastors of the large towns claiming special preëminence and power as peculiarly the successors of the apostles, and that this claim came gradually to be admitted, and was at last permanently established. They maintain, however, that the admission of this claim was never by any means universal; that the Paulicians in the 7th century, and after them the Waldenses and Albigenses, earnestly protested against all encroachments on presbyterian simplicity; and that when the reformation came, there was a vast preponderance of opinion among the leaders in that enterprise in favor of the presbyterian system; and the reformed churches in France, Germany, Holland, Hungary, Geneva, and Scotland were thoroughly presbyterian, both in principle and practice. Presbyterianism, as it has long existed in these several countries, is substantially the same system, differing only in minor details, and chiefly in the names and arrangements of their several ecclesiastical assemblies. —PRESBYTERIAN CHURCH IN SCOTLAND. The church or kirk of Scotland may be said to have had its remote origin in the first introduction of the principles of the reformation into that country, about 1527. This measure was met by a vigorous opposition on the part both of the sovereign and of the priesthood, while the greater part of the nobility espoused the interests of the people. When Andrew Melville arrived in Scotland from Geneva, in 1574, he found a state of things in many respects favorable to the design of introducing the Presbyterian polity in Scotland; and this he actually effected in 1592. James VI. was intent upon the restoration of episcopacy, even before his accession to the English throne; and after that event he was enabled to accomplish his object. But Charles I., with a view to assimilate in all respects the churches of England and Scotland, determined to introduce a liturgy, which in Scotland had been disused since the reformation, together with a set of canons abolishing the control over ecclesiastical measures which had been conceded to the inferior church judicatories. All this met with a prompt opposition from the multitude, and the clergy were reproached and insulted on every side. The dissatisfied in Scotland, and those who were disaffected toward prelacy in England, entered into a combination binding themselves, by the well known "Solemn League and Covenant" to exterminate prelacy, as being nothing better than a corrupted form of Christianity; and they lent their full influence to the carrying out of those measures which resulted in the death of Charles and the establishment of the commonwealth. Upon the restoration of Charles II., episcopacy was reëstablished in Scotland; but the Presbyterians still resolutely adhered to their principles, and upon the abdication of James II. they confidently anticipated the triumph of their cause. Though William III. was bent on preserving the same form of ecclesiastical government both in England and Scotland, the bishops refused to transfer their allegiance to him, and by this means the way was opened for that establishment of presbytery which had been urged upon him by some of his most zealous adherents, and which was ratified by an act of parliament in 1690. Thus, Scotland and England having been separate kingdoms at the time of the reformation, a difference of circumstances in the two countries ultimately led to different religious establishments; and when the treaty of union was formed in 1707, it was agreed by both kingdoms that episcopacy should continue in England, and Presbyterianism should be the only religious system recognized by the state in Scotland. The only confession of faith legally established before the revolution of 1688, is that which is published in the "History of the Reformation in Scotland," attributed to John Knox. It consists of 25 articles, and was the confession as well of the Episcopal as of the Presbyterian church. The Covenanters, indeed, during the commonwealth, adopted the Westminster confession. At the revolution this confession was received as the standard of the national faith; and it was ordained by the same acts of parliament which settled Presbyterian church government in Scotland, "that no person be admitted or continued hereafter to be a minister or preacher within this church unless he subscribe the [that is, this] confession of faith, declaring the same to be the confession of his faith." By the act of union in 1707, the same is required of all professors, principals, regents, masters, and others bearing office. The Westminster confession of faith then, and what are called the larger and shorter catechisms, contain the publicly recognized doctrines of this church; and it is well known that these formularies are an embodiment of the Calvinistic faith. There is no liturgy or public form of prayer used in the church of Scotland, the minister's only guide being the "Directory

r the Public Worship of God," which pre-
ribes the matter rather than the exact lan-
age of public devotions. There is an eccle-
astical law requiring the administration of the
ord's supper in every parish four times each
ear; but this law is not rigidly observed, and
the country parishes particularly the ordi-
nance is often administered not above once a
ear. The preparation for this ordinance con-
sts in keeping a public fast on the preceding
hursday, and attending a public service at
hich there is preaching on Saturday. They
ave no altars or chancels, and the communion
bles are introduced for the occasion. At the
rst table, the minister, after offering what is
alled the consecration prayer, proceeds to
ead the words of the institution, and then
stributes the elements to the two communi-
ants on either side of him, and the elders ad-
inister them to the rest. But before or dur-
g the services of the succeeding tables,
ddresses are made to the communicants by
ne or more of the ministers (for there are
everal present) standing at the head of the
ommunion table. In singing they use Rowse's
etrical version of the psalms of David; and
ithin a comparatively recent period there has
een introduced, by permission of the general
ssembly, a collection of translations and para-
hrases in verse of several passages of Scrip-
ure, together with a considerable number of
ymns. The provision which has been made
y the law of Scotland for the support of the
lergy of the established church consists of a
ipend, a small glebe of land, and a manse
arsonage house) and office houses. By an
ct of parliament passed in 1810, £10,000 per
nnum was granted for augmenting the small-
r parish stipends in Scotland. By this act
he lowest stipend assigned to a minister of the
stablishment is £150 sterling, with a small
um, generally £8 6s. 8d., for communion ele-
ents. Patronage was abolished in Scotland
n 1649; was revived at the restoration; was
artly abrogated at the revolution, and again
evived in 1712. The party usually termed
vangelical has been greatly on the increase in
atter years. In the appointment of minis-
ers to vacant churches, much greater at-
ention is now paid than formerly to the
ishes of the people.—The improper exercise
f patronage gave rise to the first secession
rom the established church. At the reforma-
ion, the nobility and barons seized on a large
art of the lands and other sources of ecclesi-
stical revenue belonging to the church, and
ssumed the burden of supporting the clergy
f the new faith, each within his own domain.
Persons naturally thought that they ought to
have the privilege of appointing clergymen
thus maintained at their expense; and this
practice became very common, though it did
not receive the sanction of parliament until the
reign of Queen Anne. In many cases these
appointments were violently resisted. The
doors of churches were locked on the day appointed for ordination, or the services were interrupted by the hostile demonstrations of an enraged populace, or the members of presbytery were assaulted in the streets, so that the military were sometimes summoned to protect them from outrage. Many excellent ministers denounced this system, and at length the Rev. Ebenezer Erskine of Stirling ventured to do this in a formal and very earnest manner in a discourse before the synod of Fife. Refusing to submit to the decision of this court, which was that he should be publicly rebuked for slandering the church, and obtaining no redress from the general assembly, to which he appealed, he, with 3 others, left the establishment in 1733; and they formed themselves into a separate communion, called the Associated Presbytery, which soon became a numerous and flourishing body. In 1739 a schism took place in this body, arising from a difference of interpretation of a clause of what was called the burgess oath, in which the person engaged that he would maintain and defend the religion of his country as by law established. The government deemed this oath necessary to be taken by persons clothed with civil authority, in consequence of suspected intrigues of Jesuits and the probability of a French invasion. One part of the synod argued that the taking of the oath by any of their body was unlawful, as it implied an approval of the principle of a civil establishment of religion, and of all the abuses with which it had been followed in Scotland; while the other maintained that it was simply a declaration binding the individual to defend the Protestant faith against open or secret violence. The former of these were called Antiburghers, the latter Burghers. Both prospered, while the church of Scotland was in several respects proportionally depressed. In process of time these two dissenting bodies began to approximate closely toward each other; mutual jealousies gradually died away, while the original ground of controversy, the burgess oath, being now rendered a nullity by the stability of the government at the close of the French war, no obstacle remained to the effecting of a reunion. Accordingly, in 1820, this was brought about; and the two bodies, thus merged, took the name of the United Secession church. This name was afterward changed to the United Presbyterian church, in consequence of the accession of another body called the Relief. In 1752 a clergyman named Gillespie, being required to officiate at the installation of a clergyman whom he considered unworthy of a place in the ministry, refused to perform the service, and forthwith left the church. But he took another ground than Erskine and his associates; for while they rested their secession on the unconstitutional acts of the church, he struck directly at what he deemed the root of the whole evil, and rejected the principle of an establishment altogether. This became gradually a very influential body; and its union with the United

Secession church, which all contemplated as a sure result, though it might be remote, was hastened by the course of political events in Britain. The passage of the reform bill in 1832 was hailed by the dissenters as the first step toward the separation of the church from the state, and their consequent deliverance from the disabilities to which they had hitherto been subjected. Almost all the clergymen and laity of the United Secession had taken higher ground than that assumed by the Erskines, and were therefore ready to unite with any religious body of corresponding views of Christian doctrine and church government, who would coöperate with them in systematic efforts to overthrow the establishment. Accordingly, a union was formed between these two bodies; but the controversy as to the theory of an establishment was not confined to them; it soon extended to the church of Scotland, and led to the most unexpected and important results. Various causes had been at work from the commencement of the present century to give a more earnest tone to the ministrations in the established church, and probably no two individuals contributed so much to this result as those great lights of the Scottish pulpit, Dr. Andrew Thompson and Dr. Chalmers. From 1833 to 1838 several important changes were effected, such as abolishing a plurality of clerical offices, rendering more complete the course of theological education, deposing from the ministry men of unworthy characters, reforming the system of patronage, and communicating a fresh impulse to the cause of Christian benevolence, and especially of foreign missions. But in the progress of this spirit of reform, the church came into serious collision with the state; and after a protracted course of vexatious litigation, in which the measures of the church were constantly thwarted by the civil courts, the memorable disruption took place, in which originated the Free church. (See FREE CHURCH OF SCOTLAND.) In 1860 the church of Scotland numbered 84 presbyteries, 1,178 ministers, and 1,208 churches; and the United Presbyterian church, at the same time, numbered 31 presbyteries, 526 ministers, and 536 churches. —PRESBYTERIAN CHURCH OF IRELAND. Presbyterians settled in Ireland shortly after the reformation, and were at first admitted to the privileges and emoluments of the Episcopal church. They were not tenacious about matters of church polity, for some of the pastors received ordination at the hands of a bishop, and the people conformed without scruple to some of the ceremonies of the established church. In the reign of Charles I., and during the administration of Laud, the interests of the Irish Presbyterians greatly suffered; the statutes of the college at Dublin, authorizing the admission of Presbyterians to its privileges and honors, were remodelled; their confession recognized in 1615 was set aside; and their ministers were ejected from their charges for nonconformity. During the protectorate of Cromwell they were again raised to the status of ministers of the national establishment. At the restoration, when Charles II. attempted to introduce episcopacy into Scotland, many of the inhabitants took refuge in Ireland, and thereby the cause of Presbyterianism received a fresh impulse. This was not diminished by the accession of William, prince of Orange, to the British crown; for he had been educated in Holland to a decided preference for the doctrines and discipline of that church. Nor did subsequent events tend to lessen his respect for the adherents of that system in Ireland; for when James II. landed there, with a view through the invasion of this kingdom, of overturning the government, the Presbyterians rallied around the standard of their Protestant champion, and by their memorable defence of Londonderry, as well as the assistance they rendered at the battle of the Boyne, materially contributed toward the success of his arms. As a testimony of his gratitude, he doubled the sum originally given for the support of their ministers, hence known as the *regium donum.* In consequence of the increase of churches, as well as the greater expensiveness of the means of living, the sum has been repeatedly augmented by the crown, and is now £70 each. In [illegible] the Presbyterian church was composed of the following bodies: the general synod of Ulster, the Presbyterian synod of Munster, the presbytery of Antrim, and the Seceders and Covenanters. The first two and most prominent of these have since united, forming a body which embraces 5 synods, 36 presbyteries, 491 congregations, and 593 ministers, and raises annually for missions and missionary schools about £9,000, beside sustaining various other evangelical enterprises. Though recognizing the principle of a civil establishment of religion, its views of the subject are more in harmony with those of the Free church than of the established church of Scotland.—PRESBYTERIAN CHURCH IN THE UNITED STATES. The Presbyterian church of the United States is undoubtedly to be reckoned as a daughter of the church of Scotland. Presbyterians began to emigrate from Scotland and the north of Ireland to the American colonies as early as 1689; and they quickly manifested a disposition to reproduce here their own peculiar institutions. The first and largest churches were established in Pennsylvania and Maryland, two colonies distinguished from the earliest times for their just notions of religious liberty. The Puritan element early found its way into the body from New England, and the reformed churches of the continent of Europe have from time to time made contributions to it; but the original organization has always remained substantially the same. The ministers of whom we first hear as preaching and laying the foundation of churches were the Rev. Francis McKemie and the Rev. John Hampton, the former from the north of Ireland, the latter from Scotland, both of whom appear to have sent to this country by a body of dissent- in London for the purpose of preaching the spel in the middle and southern colonies. ey fixed their residence on the eastern shore Virginia, near the borders of Maryland, and lied forth on their preaching tours in every ection where their evangelical labors were ely to be acceptable. It is ascertained that ere were several churches established some me before the close of the 17th century. In aryland there were the churches of Rehoboth, ow Hill, Upper Marlborough, Monokin, and comico, the first mentioned of which is com- nly considered the oldest, and was probably rmed as early as 1690. The church on Eliza- eth river in Virginia is supposed by some to ate back to nearly the same period. The urches in Freehold and Woodbridge, N. J., ere constituted in 1692; and the first church Philadelphia, as nearly as can be ascertained, 1698. In New Castle, Del., in Charleston, C., and in some other places, Presbyterian urches were planted at a very early period. the latter part of 1705, or early in 1706, a resbytery was formed under the title of the esbytery of Philadelphia, among whose mem- ers were the Rev. Messrs. Francis McKemie, ohn Wilson, Jedidiah Andrews, Nathaniel aylor, George McNish, John Hampton, and amuel Davis. Mr. Andrews was from New ngland, and was graduated at Harvard col- ege in 1695; the rest were all emigrants from cotland or Ireland. As early as 1716 the Pres- byterian body had so far increased that some ew organization was thought desirable; and ccordingly there were constituted, instead of one, four presbyteries, namely, those of Philadelphia, of Newcastle, of Snow Hill, and of Long island; and these presbyteries were formed into a synod, under the name of the synod of Philadelphia. Shortly before this arrangement took place, several churches, with their ministers, in East and West Jersey, and on Long Island, hitherto Congregationalists, had connected themselves with the Presbyterian church. From the period of the formation of the first synod in 1716, the body increased rapidly by means of emigrants, not only from Scotland and Ireland, but from Wales, France, Holland, and Switzerland; while numbers from New England also were induced, from local considerations or other circumstances, to cast in their lot with this denomination. The consequence was that the Presbyterian church began to assume a somewhat heterogeneous character, and the harmony of its operations was proportionately diminished. The points on which the conflicts of opinion were most strongly marked, were the examination of candidates for the ministry on experimental religion, the strict adherence to presbyterial order, and the requisite amount of learning in those who sought the ministerial office. In the several presbyteries these points were discussed with great and often intemperate zeal. Two distinct parties were now formed; those who were more zealous for orthodoxy, for the rigid observance of Presbyterian rule, and for a thoroughly educated ministry, were called the old side; while those who looked upon departures from ecclesiastical order with more forbearance, and were less particular in respect to other qualifications for the ministry, provided they could have evidence of genuine piety, were called the new side or new lights. In 1729 the synod passed what was commonly called the adopting act, which consisted of a public authoritative adoption of the Westminster confession of faith and catechisms, and made it imperative that not only every candidate, but every actual minister of the church, should, by subscription or otherwise, in the presence of the presbytery, acknowledge these instruments respectively as their confession of faith. This act had to encounter great opposition, especially from those ministers who had come from England, Wales, and the New England churches. The old side, or strict Presbyterians, having thus gained their main point, the other side felt that something was to be conceded to them also; and accordingly, in 1734, they brought an overture to the synod, directing "that all candidates for the ministry should be examined diligently as to the experience of a work of sanctifying grace on their hearts, and that none be admitted who are not in a judgment of charity serious Christians." Though this overture was adopted unanimously, it was the harbinger of great disquietude. The two acts, embracing the favorite objects of both parties, it was found difficult to carry into execution; for the practice of the several presbyteries was decided by the accidental circumstance of one party or the other being in the ascendant; and this occasioned much debate, and sometimes painful collisions, at the synodical meetings. In 1738 the strict Presbyterians prevailed on the synod to pass an act directing "that young men be first examined concerning their literature by a committee of synod, and obtain a testimonial of their approbation before they can be taken on trial before any presbytery." The presbytery of New Brunswick, regardless of this synodical decree, proceeded almost immediately to take Mr. John Rowland on trial, and shortly after licensed him to preach. This brought that presbytery and the synod into direct conflict; the consequence of which was that, at the next meeting of the latter body, Mr. Rowland's license was formally annulled. One member of the Philadelphia presbytery, however (William Tennent, senior), recognized the validity of his license by inviting him to preach; and when some of his congregation made complaints against him to his presbytery, he earnestly defended his course, denied the authority of the presbytery to act in the case, and "contemptuously withdrew;" whereupon the presbytery censured his conduct as "irregular and disorderly." This took place in Oct. 1739. Within a few weeks after, the presbytery of New Brunswick, adhering to the ground which they had already taken, proceeded to ordain Mr. Rowland to the work of the ministry; and he continued a member of that presbytery until 1742, when he was dismissed to join the presbytery of New Castle. About this time Whitefield paid his second visit to America. The great revival that took place in connection with his labors was differently viewed among the ministers of the Presbyterian church, as well as among those of New England; the new side regarding it with almost unmixed favor, while the old side had a sharp eye for all the irregularities attending it, and were not slow to pronounce the whole a delusion. Undue warmth of feeling and speech, improper inferences, and even mutual crimination, were indulged in, until at length, in 1741, the synod was rent asunder, the old side constituting the synod of Philadelphia, the new side the synod of New York. Soon after the separation, the synod of New York began to look toward the education of its future ministers in taking measures for the establishment of the college of New Jersey. This institution commenced its operations in Elizabethtown in 1746, but was removed to Newark the next year, where it remained till 1757, when it was finally removed to Princeton. Meanwhile the academies of New London and Newark in Delaware, under the Rev. Francis Allison and the Rev. Alexander McDowall, were liberally patronized by the old side. An intense rivalship grew up between the institutions of the respective parties, which served to increase not a little their mutual hostility. But the contest finally gave way under the influence of time. Both parties gradually became convinced that they had acted improperly, and began at length to meditate a reunion. In 1749 the synod of New York made the first overtures in that direction; but it was not till 1758, making the period of separation about 17 years, that the desired consummation was reached. In the course of that year, mutual concessions having been made, the articles of union in detail were happily adjusted, and the synods united under the title of "the synod of New York and Philadelphia." At the time of the disruption the old side was the more numerous, but before the reunion the new side had become so. Among the ministers that were most conspicuous during this period of separation and conflict, were some of those mentioned above, who still survived, together with the 4 sons of the Rev. William Tennent—Gilbert, William, John, and Charles—President Dickinson of Elizabethtown, President Burr of Newark, President Davies, President Finley, the Blairs, &c., all of whom ranked as new side men. The Rev. Messrs. John and Samuel Thompson, Dr. Francis Allison, the Rev. Robert Cross, and several others, were among the most prominent on the old side. From the period of the reunion, the Presbyterian body went on in a good degree of prosperity, considering the disturbed state of the country, until the close of the revolutionary war, when they could reckon about 170 ministers, and a few more churches, chiefly in the states of New York, New Jersey, Pennsylvania, Delaware, Maryland, Virginia, and the Carolinas. At the meeting of the synod of New York and Philadelphia in May, 1785, the independence of the United States being now established, that judicatory began to take those steps for revising the public standards of the church, which led to their adoption and establishment on the present plan. A committee, consisting of Drs. Witherspoon, Rodgers, Robert Smith, Patrick Allison, Samuel Stanhope Smith, John Woodhull, Robert Cooper, James Latta, George Duffield, and Matthew Wilson, was appointed to "take into consideration the constitution of the church of Scotland and other Protestant churches," and to form a complete system for the organization of the Presbyterian church in the United States. In May, 1788, the synod completed the revision and arrangement of the public standards, and ordered them to be printed and distributed for the government of the several judicatories of the church. The new arrangement consisted in dividing the old synod into 4 synods, namely, the synods of New York and New Jersey, of Philadelphia, of Virginia, and of the Carolinas, and constituting over these, as a bond of union, a general assembly, of essentially the same type with the general assembly of the church of Scotland. The Westminster confession of faith was adopted with three slight alterations, and the larger and shorter catechisms with but a single alteration; and a form of government and discipline and a directory for public worship, drawn chiefly from the standards of the church of Scotland, with such modifications as the U. S. form of government and the state of the church in this country were thought to demand, completed the system. Since the date of the revisal and arrangement just mentioned, no alteration has been made either in the confession of faith or in the catechisms of the church. The form of government and discipline have undergone two revisions, and a third is now (1861) in progress.—In 1801 a "plan of union between Presbyterians and Congregationalists in the new settlements" was formed, with a view to prevent disagreement between the two denominations, and to facilitate their coöperation in carrying forward various evangelical enterprises. This arrangement continued 36 years, and under it were formed hundreds of churches in the states of New York and Ohio. Previous to 1830 it had become apparent that there were really two parties in the Presbyterian church, the one favoring a more rigid, the other a less rigid construction of the standards of the church, which, though not often brought into actual collision, had occasion sometimes, in meeting a test question, to indicate their distinct existence. This was especially true of the celebrated case of the Rev. Albert Barnes, which, more decisively than any other which had previously occurred, pointed to a proaching disruption of the church. From s time the parties assumed toward each other more and more opposing attitude, with each cessive meeting of the general assembly, till 1837, when, after an intense conflict, the an of union was abrogated, and the 4 syn- ds of Genesee, Geneva, Utica, and the West- n Reserve were adjudged as no longer nstituent parts of the Presbyterian church; d the division thus commenced was con- mmated the next year. Since that period e Presbyterian church has consisted of two stinct bodies, known as the Old and New hool, entirely independent of each other. t the first meeting of the general assembly 1789, there were from 180 to 190 min- ters belonging to the whole Presbyterian dy. These were distributed into 4 synods d 17 presbyteries, embracing a large num- r of vacant congregations. In 1837, pre- ous to the rescinding of the western synods, e Presbyterian church contained 23 synods, 5 presbyteries, 2,140 ministers, 2,865 church- , and 220,557 communicants. In 1860 the ld School Presbyterian church contained synods, 171 presbyteries, 2,693 ministers, 592 churches, and 292,857 communicants. The ew School Presbyterian church had at the me time 23 synods, 104 presbyteries, 1,527 nisters, 1,483 churches, and 134,933 commun- icants. The aggregate of both bodies is 55 ynods, 275 presbyteries, 4,220 ministers, 5,075 hurches, and 427,790 communicants. The Old School church has boards of domestic mis- ions, foreign missions, education, publication, nd church extension. The New School has ommittees of publication, church erection, hurch extension, education, foreign missions, nd home missions. The amount contributed o the Old School body in the year ending May, 860, was $2,357,296; the amount contributed n the New School body during the same year as $305,985; total, $2,663,281. Connected ith the Old School are 6 theological semina- ies, viz.: Princeton, N. J.; Western, Allegha- ny, Penn.; Union, Prince Edward, Va.; Dan- ville, Ky.; and of the North-West, Chicago, Ill. There is also a seminary, not under the mmediate care of the general assembly, in Co- lumbia, S. C. In the New School there are 5 theological seminaries, viz.: Union, New York city; Auburn, N. Y.; Lane, near Cincinnati, O.; Blackburn, Carlinville, Ill.; and Lind, Chicago, Ill.—Notwithstanding Presbyterian- ism has never prevailed extensively in New England, it has had a distinct and independent existence there from a very early period. The French church in Boston, formed of Huguenots about the year 1687, was the first church organized on a Presbyterian basis, but was continued no longer than while its service was conducted in the French language. The first Presbyterian organization in New England of any permanence dates back to about the year 1718, when a large number of Presbyterians, with 4 ministers, emigrated to this country from the north of Ireland. For some time, in cases of difficulty, the ministers and elders were wont to assemble informally, and hold what might be called *pro re nata* meetings; and where they were unable to reach a satisfactory result, they sometimes asked advice of the synod of Ireland. In 1745 the ministers resolved, as preparatory to the step they were about to take, to observe, in connection with their congregations, the third Wednesday of March as a day of fasting, humiliation, and prayer. On April 16 following, the Rev. Messrs. John Morehead of Boston, David McGregor of Londonderry, and Ralph Abercrombie of Pelham, with Messrs. James McKeen, Alexander Conkey, and James Hughes, met in Londonderry, and being "satisfied as to the divine warrant, with dependence on God for counsel and assistance, they, by prayer, constituted themselves into a presbytery, to act, as far as their present circumstances will permit them, according to the word of God and the constitution of the Presbyterian church of Scotland, agreeing to that perfect rule." The body was called the Boston presbytery, and met, according to adjournment, in that town, Aug. 13, 1745. From the close of the year 1754 till Oct. 1770, there is a chasm in the records; but at the last mentioned period the presbytery consisted of 12 congregations and as many ministers. At a meeting held at Seabrook, N. H., on May 31, 1775, the presbytery resolved to divide itself into 3 distinct bodies, viz., the presbyteries of Salem, of Londonderry, and of Palmer; and the 3 presbyteries, thus organized, were then formed into a synod called the synod of New England, which held its first meeting at Londonderry, Sept. 4, 1776. At Boothbay, Me., on June 27, 1771, a new presbytery was erected, called the presbytery of the Eastward, consisting of 3 ministers and 4 ruling elders, representing 4 churches. It had no connection with the Boston presbytery, and its origin is said to have been in some way connected with the removal of the Rev. John Murray to Boothbay. It never exhibited on its roll more than 8 ministers. Its last recorded adjournment now known was to meet at New Boston, N. H., on the first Wednesday of Oct. 1792. The only relic of this presbytery known to exist is a curious volume printed in 1783, with the following title: "Bath-Kol. A Voice from the Wilderness. Being an humble Attempt to support the sinking Truths of God against some of the principal Errors raging at this time. Or a joint Testimony to some of the grand Articles of the Christian Religion, judicially delivered to the Churches under their care. By the First Presbytery of the Eastward." In Sept. 1782, the synod of New England, finding their numbers considerably reduced in consequence of existing difficulties, agreed to dissolve and form themselves into one presbytery, under the name of the presbytery of Salem. For two succeeding years this presbytery met regularly in Massachusetts proper, but after this its meetings were held in the district of Maine. Its last meeting was held at Gray, Sept. 14, 1791, at the close of which it adjourned *sine die*. The third Associate Reformed presbytery, afterward called the Associate Reformed presbytery of Londonderry, was formed in Philadelphia, Oct. 31, 1782, and held its first meeting at Londonderry, N. H., on Feb. 11, 1783. It ceased to belong to its original denomination in 1802, and was an independent presbytery until 1809, when it was received into the synod of Albany, and has since continued under the name of the presbytery of Londonderry. The presbytery of Newburyport was formed by the concurrent action of the presbytery of Londonderry and the synod of Albany. It held its first session in Boston on Oct. 27, 1826, and its last on Oct. 20, 1847, when it became reunited to the presbytery of Londonderry. The presbytery of Connecticut, consisting of several ministers and churches previously belonging to the presbytery of New York, was constituted by the synod of New York, Oct. 15, 1850, and held its first meeting at Thompsonville on Oct. 29.—UNITED PRESBYTERIAN CHURCH OF NORTH AMERICA. As this body is composed of the Associate Reformed and the Associate churches, it may be proper to present an outline of the history of each of these bodies up to the time of the union. 1. *Associate Reformed Church.* In 1680 Lord Cardross took measures for the establishment of a colony in South Carolina, with a view to furnish a place of refuge to his persecuted brethren. This was formed at Port Royal; but, in consequence of an invasion by the Spaniards, the colony was abandoned in 1688. Many, however, remained in Carolina, who were gathered into congregations under the care of a presbytery, which continued to exist until about the close of the 18th century. The only one of these churches now remaining is the old Scots' church in Charleston. From 1660 to 1688 a large number of Presbyterians (amounting, according to Wodrow, to about 3,000) were transported to the American plantations and sold as slaves. They were for the most part sent to Virginia, Pennsylvania, and New Jersey; but scarcely any traces of their history now remain. In 1736 the Associate presbytery of Scotland received a letter from a number of persons in Londonderry, Chester co., Penn., requesting that an ordained minister or a probationer might be sent to them, and promising that all the expenses of the mission should be defrayed by themselves; but the circumstances of the presbytery did not then allow them to comply with the request. The first minister sent to this country by the Secession church was the Rev. Alexander Gellatly, who arrived in 1751, and, after a laborious ministry of 8 years, died at Octorara, Penn. The Covenanters, or Reformed presbyterians, sent out the Rev. Mr. Culbertson in 1751; and in 1774 he was followed by Messrs. Lind and Dobbin. Of these two denominations the Associate Reformed church was made up. In 1754 the Burgher synod, in consequence of repeated and earnest applications, resolved upon establishing a mission in America, though their purpose was not carried out until 1764, when the Rev. Thomas Clark, minister of Ballybay in Ireland, in company with the greater part of his congregation, emigrated to this country, and settled at Salem, Washington co., N. Y. Two other ministers of the same communion followed them two years after, though one of them subsequently returned to Scotland. The Burgher ministers, not being disposed to keep up a separate organization on this side of the Atlantic, united with their brethren; but the union was disturbed by the refusal of the Scottish synod to approve of it. The revolution of 1776 was chiefly instrumental in bringing about the union which produced the Associate Reformed church. During the progress of the war, several conventions were held between the members of the Associate and the Reformed presbyteries with a view to the accomplishment of this end; the result of which was that 3 presbyteries met in Philadelphia in Oct. 1782, and formed themselves into a synod under the name of the Associate Reformed synod of North America, on a basis consisting of the following articles: "1. That Jesus Christ died for the elect. 2. That there is an appropriation in the nature of faith. 3. That the gospel is addressed indiscriminately to sinners of mankind. 4. That the righteousness of Christ is the alone condition of the covenant of grace. 5. That civil government originates with God the Creator, and not with Christ the Mediator. 6. The administration of the kingdom of Providence is given into the hand of Jesus Christ the Mediator; and magistracy, the ordinance appointed by the moral Governor of the world, to be the prop of civil order among men, as well as other things, is rendered subservient by the Mediator to the welfare of his spiritual kingdom, the church, and has sanctified the use of it and of every common benefit, through the grace of the Lord Jesus Christ. 7. That the law of nature and the moral law revealed in the Scriptures are substantially the same, although the latter expresses the will of God more evidently and clearly than the former, and therefore magistrates among Christians ought to be regulated by the general directory of the Word as to the execution of their office. 8. That the qualifications of justice, veracity, &c., required in the law of nature for the being of a magistrate, are also more explicitly revealed as necessary in the Holy Scriptures. But a religious test, any further than an oath of fidelity, can never be essentially necessary for the being of a magistrate, except when the people make it a condition of government. 9. That both parties, when united, shall adhere to the Westminster confession of faith, the catechisms, the directory for worship, and propositions concerning church government. 10. That they shall claim the full exercise of church discipline ithout dependence upon foreign judicatories." pon this basis all the members of the Reformed presbytery, and all the Associate ministers with the exception of two members of n presbytery of Pennsylvania (Messrs. Marshall and Clarkson), united. A small minority of the people in the two communions also eclined to enter into it; and in these minorities have been preserved the Covenanter or eformed Presbyterian denomination on the one hand, and the Associate on the other. The arliest settlements of the Associate Reformed hurch were in Pennsylvania, within the Cumberland valley; but colonies from these emigrated to South Carolina and Georgia, New York, Kentucky, and even to New Hampshire and Maine. One of the first acts of the synod, after its organization in 1782, was the adoption of a series of articles, afterward published under the name of "The Constitution of the Associate Reformed Church;" but these articles were severely attacked both by the Seceders and Covenanters, and were finally laid aside for a fuller exposition of the church's faith. The result was that the Westminster confession and the catechism, after a careful revision at several successive meetings of synod, in the articles relating to the power of the magistrate, were published in a volume in 1799, entitled "The Constitution and Standards of the Associate Reformed Church in North America." The ground occupied by this body was substantially the same with that held by the church of Scotland. For 20 years the growth of the church was very rapid; and this led to the adoption of a measure in 1802, which proved premature and adverse to its prosperity, namely, the division of the church into the 4 provincial synods of New York, Pennsylvania, Scioto, and the Carolinas, under a representative general synod. In 1796 the initiatory steps were taken for the establishment of a theological seminary; and, the requisite funds having been collected, at a meeting of the synod in 1804 the plan of the seminary was framed. Dr. John M. Mason was chosen professor of theology; and the sessions of the seminary began in the autumn of the same year in the city of New York. This was the second theological seminary established in the United States. Dr. Mason's work on "Catholic Communion," published in 1816, was regarded in many parts of the church as a prodigious heresy in regard to the subject of which it treated; and this, in connection with some other grounds of complaint, led the entire synod of Scioto, in 1820, to withdraw from the superintendence of the general synod. In 1821 the synod of the Carolinas petitioned the general synod to be erected into an independent synod, on the ground that they were so distant from the place at which the general synod usually assembled that it was impossible that they should be represented in it. The request was granted. For many years after that the southern synod gained but little in numbers, though in later years it became more prosperous; while the western synod went on rapidly extending itself and becoming more and more vigorous every year. About the time of the separation of the western synod, an unsuccessful attempt was made to unite the Associate Reformed and the Reformed Dutch churches, under the name of the Reformed Protestant church of North America. Immediately after this, measures, which were considered by many of very dubious propriety, were adopted for effecting a union between the Associate Reformed and the Presbyterian bodies; the consequence of which was that a portion of the former church became incorporated with the latter, and the library of the Associate Reformed church was immediately removed from New York to Princeton; though, as the result of a legal process, it ultimately fell back into the hands of its original owners. The synod of New York now resumed its ordinary meetings, and took the place of the general synod as the supreme judicatory of the church in the northern states. But the interests of the church continued in a languishing state till 1829, when the synod resolved to revive the seminary, whose operations had been suspended in 1821, and to establish it at Newburg, under the care of the Rev. Joseph McCarroll, D.D., who was at the same time chosen professor of theology. It thus appears that since 1822 the Associate Reformed church has existed in three independent divisions, at the North, the West, and the South. An attempt was made in 1837 to revive the general synod on the old footing, but it proved a failure.

2. *The Associate Presbyterian Church.* From 1782, the period of the formation of the Associate Reformed church, the Associate church was gradually increased by ministers sent out from Scotland, and also by the return of a considerable part of those who had previously joined the union. The first institution for the purpose of educating students in theology by this body was established in 1793, under the care of the Rev. John Anderson, D.D., of Beaver co., Penn., who continued to serve as sole professor of theology until 1818, when he resigned on account of old age. The presbytery of Pennsylvania, being unable to meet the applications for preaching which were made from Kentucky and Tennessee, directed the applicants to apply directly to the synod in Scotland for missionaries. They did so; and in answer to the petition, the synod sent two missionaries (Messrs. Armstrong and Andrew Fulton) to Kentucky, with authority to constitute themselves into a presbytery. These missionaries arrived in Kentucky in the spring of 1798, and in November following formed themselves with ruling elders into a presbytery, by the name of the presbytery of Kentucky. This accession of strength enabled these presbyteries to form themselves into a synod; and accordingly the synod, or court of review, designated as the Associate synod of North

America, was constituted at Philadelphia in May, 1801. The synod consisted of 17 ministers, who were divided into 4 presbyteries, namely, of Philadelphia, of Chartiers, of Kentucky, and of Cambridge. Until the year 1818 appeals might be taken from the synod to that of Scotland; but at that time it was declared a coördinate synod by the general Associate synod of Scotland. Between the years 1838 and 1840 several ministers were deposed or suspended for various offences, who subsequently formed themselves into a synod, and assumed the name of the Associate synod of North America. Two ministers also in the South, one in Virginia, the other in South Carolina, who were suspended on account of their connection with slavery, became united with the Associate Reformed synod of the South. A minister of the presbytery of Miami also joined with a suspended minister of the same presbytery and formed what they denominated the Free Associate presbytery of Miami.—In May, 1858, the Associate Reformed and the Associate churches, having been separated for more than three quarters of a century, were united again upon a common basis, under the name of the United Presbyterian church in North America. A small number on each side protested against the union. In 1860 this branch of the church embraced a general assembly, 4 provincial synods, 43 presbyteries, 447 ministers, 674 congregations, and about 60,000 communicants. The amount of its contributions for benevolent purposes during 1860 was $253,150. It has theological seminaries at Alleghany, Penn., Xenia, O., and Monmouth, Ill. It has boards of foreign missions, of home missions, of publication, of church extension, and of education. Its periodical publications are one quarterly, one monthly, one semi-monthly, and 4 weekly newspapers.—REFORMED PRESBYTERIAN CHURCH IN AMERICA. At the union of the Associate and the Reformed churches in 1782, a considerable number of the latter as well as of the former communion refused their assent to it, and they continued their original organization. Within 10 years, 4 ministers emigrated from Europe, to aid in maintaining the Reformed Presbyterian cause, viz.: Mr. James Reid from Scotland, who returned to his own country when his missionary tour was accomplished, and Messrs. McGarragh, King, and McKinney, the latter of whom arrived in 1793. The 3 last named gentlemen regulated the affairs of the church as a committee of the Reformed presbytery in Scotland. This, however, was a mere temporary expedient, and its end having been accomplished, Messrs. McKinney and King, in connection with Mr. Gibson, who had then lately come from Ireland, proceeded in 1798 to constitute a presbyterial judicatory independent of all foreign control. This presbytery was styled the Reformed presbytery of the United States of America. In arranging the terms of her communion, she declared that she adopted the Reformed Presbyterian system only in so far as it presents common truth, and "binds to duties not peculiar to the church in the British isles, but common in all lands." Soon after the organization of the presbytery, 4 young men were licensed to preach the gospel, who became efficient missionaries in different parts of the United States. In 18[illegible] a synod, composed of 8 presbyteries, was constituted under the name of the synod of the Reformed Presbyterian church in the United States of North America. In 1825 the supreme judicatory received the form of a representative assembly, composed of delegates from presbyteries, and styled the general synod. The ecclesiastical standards of this church are the Westminster confession of faith and catechisms, and a "Declaration and Testimony," published in 1848. In declaring her approbation of the Westminster confession of faith, she makes the following disclaimer: "To prevent all misunderstanding of the matter of the second article of this formula, which embraces the confession of faith and catechisms, it is declared in reference to the power of the civil magistrate in ecclesiastical things, that it is not now, and never was, any part of the faith of the Reformed Presbyterian church, that the civil magistrate is authorized to interfere with the church of God, in the assertion, settlement, or administration of her doctrine, worship, and order, or to assume any dominion over the rights of conscience. All that appertains to the magistratical power in reference to the church is the protection of her members in full possession, exercise, and enjoyment of their rights. The magistratical office is civil and political, and consequently altogether exterior to the church." Some Reformed Presbyterians have entertained the opinion that the constitution and government of the United States are essentially infidel and immoral; and principally on this ground a number of ministers and private members, in 1838, seceded from the general synod of the church, and formed a separate organization. Reformed Presbyterians are scattered over the middle and western states, and they have a few congregations at the South. The church consists of 7 presbyteries, 56 ministers, and 114 churches and stations. The amount of their contributions to benevolent objects in the year ending May, 1860, was $10,319.24. They have boards of domestic missions, of foreign missions, and of education, and one theological seminary; and they also publish one weekly newspaper.

PRESCOT, a town of Lancashire, England, 8 m. E. from Liverpool; pop. in 1851, 46,527. It stands upon a coal field, and has long been a manufacturing town of importance. The drawing of pin wire had its origin here; and the works of watches, watchmakers' tools, and small files of superior quality are manufactured.

PRESCOTT. I. OLIVER, an American patriot, born at Groton, Mass., April 27, 1731, died there, Nov. 17, 1804. He was graduated at Harvard college in 1750, and afterward prac-

medicine. Before the revolution he was
essively major, lieutenant-colonel, and colo-
in the militia, and in 1776 was appointed
the supreme executive council of Massachu-
a brigadier-general of the militia for the
nty of Middlesex. The same year also he
ame a member of the board of war, and in
7 was elected a member of the supreme ex-
tive council of the state. After serving in
body 3 years, he declined a reëlection. In
8 he was created third major-general of
itia throughout the commonwealth, and in
l second, but soon after resigned. In this
r he received from the government a com-
sion "to cause to be apprehended, and
mitted to gaol, any person whom you shall
m the safety of the commonwealth requires
e restrained of his personal liberty, or whose
argement within the commonwealth is dan-
ous thereto." In 1779 he was made judge
probate for the county of Middlesex, and
d that position until his death. II. WIL-
M, an American patriot, brother of the pre-
ding, born at Groton, Mass., in 1726, died at
pperell, Mass., Oct. 13, 1795. He inherited
arge estate from his father, who was a mem-
r of the governor's council. In 1755 he
ved as lieutenant in the provincial army un-
r Winslow during the expedition against
va Scotia, and his conduct in that campaign
racted the favorable notice of the British
neral coöperating with Winslow, who offered
escott a commission in the royal army, which
e declined. After the war Prescott retired to
estate in Pepperell, where he resided, with
igh reputation for courage, honor, and mili-
ry skill, till 1775, when, on receiving the news
the battle of Lexington, he assembled a regi-
ent of militia of which he was colonel, and
arched to the camp at Cambridge. When
e committee of safety decided to occupy Bun-
r hill, Prescott was selected for this perilous
rvice, and on the evening of June 16 marched
Charlestown with a brigade of 1,000 men,
d threw up the intrenchments behind which
der his command the Americans met the
itish on the following day. It is the con-
mporary record, says Bancroft, that dur-
g the battle "no one appeared to have any
mmand but Col. Prescott," and that "his
avery could never be enough acknowledged
d applauded." He was among the last to
it the field, and immediately offered to re-
ke the position if the commander-in-chief
ould give him three regiments. He served in
e army for two years longer, and was present
a volunteer at the battle of Saratoga in 1777.
fter this battle he returned home, and subse-
ently sat in the legislature of Massachusetts
r several years. III. WILLIAM, LL.D., an
merican lawyer, only child of the preceding,
rn at Pepperell, Aug. 19, 1762, died in Bos-
n, Dec. 8, 1844. He was graduated at Har-
ard college in 1783, and studied law at Beverly
ith Nathan Dane, the distinguished founder
f the law professorship which bears his name

in Harvard university. At Beverly he practised his profession from 1787 to 1789, when he removed to Salem, which town he represented for several years in the legislature, and was subsequently elected by the federal party a state senator. In 1806 and again in 1813 he was offered and refused a seat on the supreme judicial bench of Massachusetts. In 1808 he removed to Boston, and in 1809 and for several years afterward was a member of the governor's council. In 1814 he was a delegate to the Hartford convention, and in 1818 was appointed a judge of the court of common pleas, which office he resigned at the end of a year. He was a delegate to the constitutional convention of Massachusetts, his last public office. The closing years of his life were spent in quiet retirement. "As a practising lawyer," says Mr. Hillard, "no person ever enjoyed in a greater degree the confidence of the community or the respect of the courts. For the last 31 years of his life there was no one in Boston whose counsel was more solicited or more valued in important matters, whether public or private." Daniel Webster, in a public address on the death of Judge Prescott, remarked that at the time of his retirement from the bar of Massachusetts he stood at its head for legal learning and attainment. IV. WILLIAM HICKLING, LL.D., an American historian, son of the preceding, born in Salem, Mass., May 4, 1796, died in Boston, Jan. 28, 1859. His mother, who died in 1852, was the daughter of Thomas Hickling, for many years U. S. consul at the Azores, and was eminently distinguished for benevolence and active charity. At the age of 12, young Prescott removed with his family to Boston, where he was placed in the academy of Dr. Gardiner, a pupil of Dr. Parr. He entered Harvard college in 1811, and was graduated in 1814. In the last year of his student life, while in the college dining hall, a classmate playfully threw at him a crust of bread, which struck one of his eyes, inflicting an injury which deprived the eye of sight except so much as sufficed to distinguish light from darkness. Excessive use of the other eye for purposes of study brought on a rheumatic inflammation, which deprived him entirely of sight for some weeks, and left the eye in too irritable a state to be employed in reading for several years. Subsequently for some years he was enabled to use it for many hours of the day, but eventually it again became so weak that during the latter half of his life Mr. Prescott could only read for a few moments at a time, and could scarcely see to write at all. Soon after leaving college he crossed the Atlantic for the benefit of his eyes, and consulted the most celebrated oculists of London and Paris, who however could give him no effectual relief. He travelled extensively in England, France, and Italy, and resided for several months at Rome and Naples. On his return to Boston after two years' absence, he married and settled for life in his father's family. He had begun the study of the law, but relinquished it in consequence of the state of his eyesight, and resolved to devote himself to literature as a profession in which he could regulate his own hours in reference to what his sight might enable him to accomplish. He had early conceived a passion for historical writing, and in 1819 determined to devote the next 10 years to the study of ancient and modern literatures, and to give the succeeding 10 to the composition of a history. He accordingly applied himself to the study of French and Italian literature, and at one time meditated writing a life of Molière, for which he made an extensive collection of materials. This project, and another for the history of Italian literature, he reluctantly abandoned because of the great amount of reading which they involved. Of his studies in this direction the chief fruits were given to the public in a series of essays in the "North American Review" on "Molière," "Italian Narrative Poetry," and "Poetry and Romance of the Italians," which, with others on kindred topics, were printed in a volume of "Miscellanies" (London and Boston, 1845), of which several editions have since been published. About 1825 Mr. Prescott began to study Spanish literature and history, and after much deliberation selected as the subject of his first work the reign of Ferdinand and Isabella. He made at great expense a collection of materials, and before beginning to write was able with the assistance of his friends in Europe to secure, as he says in the preface to the history, "whatever can materially conduce to the illustration of the period in question, whether in the form of chronicle, memoir, private correspondence, legal codes, or official documents." Among these were various contemporary manuscripts, covering the whole ground of the narrative, none of which had been printed, and some of them but little known to Spanish scholars. But when his materials were collected, his eyes, which for a time had been well enough to enable him to read a few hours each day, became worse than ever. He obtained the assistance of a reader, who however knew no language but English. "I taught him to pronounce the Castilian in a manner suited, I suspect, much more to my ear than to that of a Spaniard; and we began our wearisome journey through Mariana's noble history. I cannot even now call to mind without a smile the tedious hours in which, seated under some old trees in my country residence, we pursued our slow and melancholy way over pages which afforded no glimmering of light to him, and from which the light came dimly struggling to me through a half intelligible vocabulary. But in a few weeks the light became stronger, and I was cheered by the consciousness of my own improvement; and when we had toiled our way through 7 quartos I found I could understand the book when read about two thirds as fast as ordinary English." At a later period Mr. Prescott obtained the services of a reader acquainted with Spanish and other languages of continental Europe, and could with this aid prosecute his studies with some degree of facility. After more than 10 years of labor the "History of Ferdinand and Isabella" was ready for the press. A few copies were privately printed and shown to Mr. Sparks, Mr. Ticknor, and other friends, whose cordial approbation at length encouraged the diffident author to publish the work. It appeared in Boston and London toward the end of 1837, in 3 vols. 8vo., and was immediately received with great favor by the public. Don Pascual de Gayangos, the eminent Spanish scholar, reviewed it in the "Edinburgh Review," and pronounced it "one of the most successful historical productions of our time." Mr. Richard Ford, who was better versed in Spanish literature than any other Englishman of his day, praised it highly in the "Quarterly Review" as a work "that need not fear comparison with any that has issued from the European press since this century began." The work was soon translated into German, French, and Spanish, and the royal academy of history at Madrid elected the author a corresponding member. Six years of labor were next devoted to the "History of the Conquest of Mexico" (3 vols. 8vo., London and New York, 1848), and four years to the "Conquest of Peru" (2 vols. 8vo., London and New York, 1847). These works were received with the highest favor in all parts of the civilized world, and praises and honors were showered on the author. He was elected a member of nearly all the principal learned bodies in Europe, and in 1845 was made a corresponding member of the institute of France. In 1850 Mr. Prescott made a short visit to Europe, passing a few months in England, Scotland, and Belgium. After his return he applied himself to the composition of a history of the reign of Philip II., which he had long meditated, and for which he had made an extensive collection of books and manuscripts. The first two volumes of this work appeared in Boston in 1855, and the third in 1858. The entire history was intended to comprise 6 volumes, but was never finished. On Feb. 4, 1858, Mr. Prescott experienced a slight shock of paralysis, from the effects of which however he soon recovered and resumed his literary pursuits. Eleven months afterward, while at work with his secretary in his study, he was struck speechless by a second attack of paralysis, and died about an hour afterward. Beside his histories, Mr. Prescott wrote brief memoirs of his friends John Pickering and Abbott Lawrence, and supplied to a Boston edition of Robertson's "History of Charles V." a sequel relating the true circumstances of the emperor's retirement and death.—In person Mr. Prescott was tall and slender, with a fresh and florid complexion, and lively, graceful manners. "His personal appearance," says Mr. Bancroft, "was singularly pleasing, and won for him everywhere in advance a welcome and favor. His countenance had something that brought to t the 'beautiful disdain' that hovers on of the Apollo. But while he was high- ted, he was tender and gentle and humane, voice was like music, and one could never enough of it. His cheerfulness reached animated all about him. He could in- e in playfulness, and could also speak estly and profoundly; but he knew not to be ungracious or pedantic." A similar rait of his personal character was given n after his death by one of his secretaries in mmunication to the New York "Tribune:" r. Prescott's cheerfulness and amiability re truly admirable. He had a finely wrought, sitive organization; he was high-spirited, rageous, resolute, independent; was free m cant or affectation of any sort. Yet no noyance, great or small, the most painful ness or the most intolerable bore, could dis- b his equanimity, or render him in the least grow sullen or fretful or discourteous. He s always gay, good-humored, and manly; st gentle and affectionate to his family, most ul and gracious to all around him. He car- d his kindness of disposition not only into s public but into his private writings. In the undreds of letters, many of them of the most nfidential character, treating freely of other thors, and of a great variety of persons, which wrote at his dictation, not a single unkind or rsh or sneering expression occurs. He was to- lly free from the jealousy and envy so common ong authors, and was always eager, in con- ersation as in print, to point out the merits of he great contemporary historians whom many en in his position would have looked upon as vals to be dreaded, if not detested." In his habits he was singularly methodical, and regulated his daily life by an exact division of time. He rose early, waked by an alarm clock, and clothed himself according to the weather as indicated by the thermometer, putting on so many pounds of clothing more or less, his garments being all marked with their weight in pounds and ounces. He walked 5 miles each day in the open air, or, if the weather was stormy, in the house, in the latter case putting on his hat, boots, and gloves, and taking his cane, as if out of doors. He always walked alone, if he could without discourtesy avoid having a companion, because while walking he occupied his thoughts in composition. His father had the same peculiarity, and both father and son for many years rode out at the same hour in the morning, mounting their horses at the same door, and riding off in opposite directions. To his literary labors he gave 5 hours daily, divided into 3 nearly equal portions of time, and for 2 hours a day listened to novel reading, which he thought stimulated his imagination and enhanced the animation of his style. His favorite novelists were Scott, Dickens, Dumas, and Sue. His accounts of daily expenditures were kept with the greatest exactness, and one tenth of his income was always devoted to charity. From the middle of November to the middle of June he resided in Boston, at No. 55 Beacon street, where he had accumulated one of the finest private libraries in America, being especially rich in Italian and Spanish books. The summer was always passed at Nahant, where he had a cottage, and the autumn at Pepperell, in the farm house in which his ancestor, the commander at Bunker hill, was born and died. In the last years of his life he abandoned Nahant and established his summer residence in the neighboring town of Swampscott. He carried his books with him to his seaside and rural residences, and wrote there with his usual diligence. His mode of composition was as follows. His secretary first read to him all the books that related to the general subject, Mr. Prescott dictating occasional memoranda as the reading went on. The plan of the work was then sketched, a division into chapters made, and the authorities for the topic of the first chapter gathered together and read to him carefully, while he dictated copious notes of their contents and of the reflections or descriptions suggested by them. When the perusal of the authorities was finished, the mass of notes was read and reread to Mr. Prescott until their substance was fully fixed in his mind. He then sat down to write, using for the purpose a writing instrument made for the blind, consisting of a frame of the size of a sheet of quarto letter paper traversed by as many brass wires as there were to be lines on the page, and with a sheet of carbonated paper, such as is used for getting duplicates, pasted on the reverse side. With an ivory or agate stylus he traced his characters between the wires on the carbonated sheet, making indelible marks on the white page below. He wrote with great rapidity, in a hand so illegible that none could read it but himself and his secretary. The latter copied the manuscript as fast as written in a large and legible hand, on paper so ruled that there was twice the usual space between the lines to afford room for interlineation. When the chapter was finished, it was read to him several times, carefully revised, and again copied before being sent to the printer. He took comparatively little pains with his style, but was unwearied in his efforts to ascertain the truth of history. "The excellence of his productions," says Mr. Bancroft, "is transparent to every reader. Compare what he has written with the most of what others have left on the same subject, and Prescott's superiority beams upon you from the contrast. The easy flow of his language, and the faultless lucidity of his style, may make the reader forget the unremitting toil which the narrative has cost; but the critical inquirer sees everywhere the fruits of investigation rigidly and most perseveringly pursued, and an impartiality and soundness of judgment which give authority to every statement and weight to every conclusion." Edward Everett, in an address before the Massachusetts historical society, shortly after Mr. Prescott's death, said: "So long as in ages far distant, and not only in countries now refined and polished, but in those not yet brought into the domain of civilization, the remarkable epoch which he has described shall attract the attention of men; so long as the consolidation of the Spanish monarchy and the expulsion of the Moors, the mighty theme of the discovery of America, the wonderful genius of Columbus, the mail-clad forms of Cortes and Pizarro, and the other grim *conquistadores*, trampling new-found empires under the hoofs of their cavalry, shall be subjects of literary interest; so long as the blood shall curdle at the cruelties of Alva, and the fierce struggles of the Moslem in the East; so long will the writings of our friend be read. With respect to some of them, time, in all human probability, will add nothing to his materials. It was said the other day, by our respected associate, President Sparks (a competent authority), that no historian, ancient or modern, exceeded Mr. Prescott in the depth and accuracy of his researches. He has driven his Artesian criticism through wretched modern compilations, and the trashy exaggerations of intervening commentators, down to the original contemporary witnesses; and the sparkling waters of truth have gushed up from the living rock. In the details of his narrative further light may be obtained from sources not yet accessible. The first letter of Cortes may be brought to light; the hieroglyphics of Palenque may be deciphered; but the history of the Spanish empire, during the period for which he has treated it, will be read by posterity for general information, not in the ancient Spanish authors, not in black letter chronicles, but in the volumes of Prescott."—A life of Prescott is in preparation (1861) by Mr. George Ticknor of Boston, the historian of Spanish literature.

PRESCRIPTION (in the Roman law, *præscriptio*), a title acquired by possession, during the time and in the manner fixed by law. It is a natural and immutable principle, says Domat, that the owner of a thing shall remain so, and enjoy therefore all the rights of ownership, until his property is divested either by his voluntary act of alienation, or in some other legal mode. And it is another natural rule of the law, that he who has been for a long time in possession of a thing shall be regarded as the owner of it; because, in the first place, men are naturally careful not to give up what belongs to them, and in the second place, because it would be unreasonable to presume without proof that a possessor is a usurper. Yet, if the former of these rules, he continues, be carried to its furthest extent, it will follow that he who can show that either he, or they through whom he claims, have been owners of an estate, will recover it from the possessor, no matter how long the latter or his ancestors may have been in possession, unless he (the possessor) can show a particular divestiture of the claimant's title. If, on the other hand, it is to be imperatively presumed that possessors are in all cases owners, injustice will sometimes be done by depriving of their property those who chance to be out of possession. Some arbitrary rule must therefore be contrived to reconcile these conflicting natural rights of owners and possessors. This end would obviously be attained by prescribing a time within which those who claim to be owners, but are not in possession, shall prove their rights, and after the lapse of which possessors who have not been evicted shall be maintained in their possession. That this obvious rule is also a reasonable one will appear, when it is remembered that occupancy and continued use make the very foundation of title to things, and that the requirement of uninterrupted possession for a given period is only an application of the universal rule of acquisition. As a rule of this nature is then essential, it will be found to exist in all systems of law. Here we have to do only with the prescription of our law. The cognate subject of limitation is treated elsewhere. (See Limitation, Statutes of.)—In strictness the common law allowed only incorporeal rights, such as easements, rights of way, and watercourses, to be prescribed for. Lands and corporeal rights were provided for by the statutes of limitation. Bracton, however, who was one of the earliest writers upon the English jurisprudence, and who wrote before the statutes of limitation were so nicely developed as they now are, and who moreover borrowed much of his learning immediately from the Roman law, lays it down that undisturbed enjoyment may as well give title to corporeal as to incorporeal rights, and that was the principle of *præscriptio* in the code of Justinian. American law, though it has, like the English law, its prescription and its limitations, yet does not so strictly as that limit the application of either, but seems sometimes to hold with Bracton that prescription may as well apply to lands as to rights of common or way. So Judge Story once remarked, that "the arguments for prescription apply, it is plain, as well to lands as to incorporeal rights." (7 Wheaton, 109, 110.) The period which gives prescriptive right has varied in the law. Anciently the law required that the right claimed should have existed undisturbed from time immemorial, or, as the old phrase is, "from time whereof the memory of man runneth not to the contrary." When, by the statute of Westminster the first, in the time of Edward I., writs of right were limited to a certain period, it was thought reasonable that the period of prescription should have a like limitation, and claims of right were therefore declared to be indefeasible if they existed before the first day of the reign of *Richard I.* (July, 1189), but were invalidated if they had a later origin. By later statutes the period of limitation in real actions was still further reduced, and it would have been only reasonable to conform to it the time of legal memory or prescription. This was, however, not done, and it was left for a long time to the courts to remedy the unfairness by equitable construction. The device was hit upon by them of presuming, in case of the long enjoyment of an easement, that there had been a formal grant, of which the evidence, that is to say, the deed, was lost. If this presumption were not rebutted by proof to the contrary, the occupant's title was confirmed. The effect was, that though prescriptive right commencing after the reign of Richard I. was not sustained, for the law on that point was explicit and still imperative, yet possession for a period far less even than that of legal memory sufficed to warrant the presumption of a grant. Prescription in its old sense was rarely pleaded, and time of legal memory came to be of little importance. But later, and particularly by the statute 2 and 3 William IV., the time of prescription was definitely limited by express enactments to periods varying from 60 to 20 years, according to the circumstances and the nature of the right claimed. The tendency of all modern legislation, indeed, is to substitute a short certain period in lieu of the old immemorial prescription. This last has been abolished in France, in Austria, where the prescriptive periods vary from 6 to 40 years, and in Prussia, where they range from 10 to 50 years. In the United States the policy of the law has been to make the time of prescription analogous to that of the statutes of limitation; in other words, to apply the same rule to like cases; so that we are gradually bringing the cognate matters of prescription and limitation together again, and throwing them under virtually one title, as they should be in fact, and as they are in foreign codes. This rule of the American law is not only a plainly expedient one, but, as we have seen, it is the one by which the English period of prescription was first defined. Furthermore, the English time of legal memory was a purely arbitrary one. When then it became necessary for American law to fix such a time, there was already the precedent for settling upon an arbitrary period; but there was beside good reason why it should not follow the English rule, but should adopt one better suited than that to the age and circumstances of the country. The better opinion is that our time of legal memory was generally 60 years, and that therefore was the prescriptive period. Afterward, following the statutes of limitation, it was reduced generally to 40 years. More lately, and indeed now for a long time, adverse, exclusive, and uninterrupted enjoyment for 20 years affords in most states conclusive presumption of right. Still conforming to the statutes of limitation, the time of prescription is in some states less than that, as, for example, 15 years in Vermont and Connecticut. The doctrine of prescription is not only applicable, but in many respects peculiarly applicable to the circumstances of our country. The same arguments for it which apply everywhere else apply equally here; namely, the considerations that occupancy is universally the origin and first ground of title; that long undisturbed possessors ought to be protected in their occupancy; and that even where lands have been transferred by formal instruments of conveyance, yet these may be lost. But that the principle of prescription is introduced into our law with singular fitness will appear when it is remembered that in this country all titles, even the oldest, are comparatively recent; that unjust eviction might be in many cases easier than in older countries; that during the rapid settlement of large districts of the country the original instruments of conveyance were often rude and technically inexact; and finally, that in many localities the original settlers had no other right than that which occupancy gave them, a title which custom recognized at the time as sufficient, but of which subsequent grantees could show no written evidence.—Now, to regard briefly the particular qualities of prescription, it is to be remarked in the first place that the enjoyment of the right prescribed for must have been adverse; that is to say, it must either have invaded or limited the exercise of such a right of the owner as he could have asserted by action. Prescription therefore cannot be pleaded when possession has been enjoyed by the mere permission or license of the owner, for this recognizes the owner's title; in short, the possession must have been enjoyed as of the possessor's right. Possession must also have been uninterrupted; for he who ceases to hold possession seems himself to admit his lack of title. Claim of prescriptive right is also extinguished by unity of possession. Thus, if B has acquired by long enjoyment a right to have water flow through his land by artificial courses upon A's estate, and then A buys B's land, and makes a conveyance of the land which once was B's, the grantee cannot claim a prescriptive right to the water courses. Moreover, the right claimed by prescription must have been certain and reasonable. There can be no prescriptive right to do a wrong, or any thing that would be a nuisance to another; nor can exclusive right be prescribed for in respect to a common privilege, for example, by one who has pastured his cattle for the prescribed period upon a common or a highway, or has enjoyed a way along a beach which is used in common by fishermen, fowlers, weed-gatherers, *&c.* Yet, as a member of the community, an individual may assert prescriptive right in a public easement, as for example in a common landing place or a highway. The claim of prescription must be proved substantially as it is pleaded; yet slight and unessential variations in the proof will not invalidate the claim of right. In almost all the states the doctrine of prescription is now regulated, in its application to the various classes of rights, by express statute provisions. Generally 20 years' uninterrupted possession is required for the acquisition of real rights; and by statute in Massachusetts, and by substantially the same provisions in Maine, Indiana, and probably other states, the owner of land may defeat prescriptive acquisition by notifying the occupant of his intention to dispute the title. This notice operates in behalf of the real owner as a legal interruption to break up the running of the prescriptive time; while the claimant may treat it as a trespass or a tortious intrusion on his presumed ownership, and bring an action to determine the right.

PRESERVATION OF FOOD. All articles used as nutriment (see Aliment) are themselves of organic nature, and consequently subject to rapid decay. The elements of which they consist, chiefly carbon, hydrogen, oxygen, and nitrogen, are loosely held in their various combinations, and constantly tend to return to the simpler and more stable compounds recognized as inorganic. Thus carbon, which constitutes about one half the weight of dry vegetable matters and a large proportion of animal substances, is ever ready to leave the elements that hold it in these bodies, and, uniting with a due proportion of oxygen, escape in the form of carbonic acid gas; hydrogen in like manner seeks its atom of oxygen, with which to form water; nitrogen combines with hydrogen to produce the volatile ammonia, and more hydrogen is still removed in combination with sulphur in the noxious gas sulphuretted hydrogen. (See Combustion, Eremacausis, Fermentation, and Putrefaction.) Food being irregular in its supplies, and also required in places where it is not naturally produced, it is important to be able to check the tendency to decay, that stores of it may be retained for use whenever and wherever needed. As the presence of water or almost any fluid facilitates these changes, mechanically by increasing the mobility of the particles, and also by the chemical reaction of its elements, the permanence of the compounds cannot fail to be increased by its removal. For this reason, the practice of drying meats in the sun or by a fire has been very generally adopted, even among rude nations. The flesh of the buffalo and the deer is thus preserved by the Indians of the West, and the Mexicans and Spanish Americans have long applied the same method to the preservation of beef, which, cut into long strips, dipped in brine, and hung upon lines to dry in the sun, they designate *tasajo*. Such meat may be reduced to powder by pounding it in a mortar, and thus prepared it is sometimes mixed with corn meal and packed in tight bags of skin to be kept as long as need be. It is also sometimes mixed with half its weight of melted fat, or with marrow and dried currants or berries, and again with flour, oatmeal, or powdered hard bread. Such is the pemmican of the north-west *voyageurs*. Glue is the gelatine of animal bodies preserved by thorough drying. Fish are also preserved by the same method. Codfish taken on the banks of Newfoundland are immediately split open, and thrown with some salt into the hold of the vessel, whence they are afterward taken and spread out upon rude stands of wicker work called flakes, and left for weeks to become thoroughly dry. Salt, which is used as an auxiliary in these processes, is effective from its property of abstracting moisture from [illegible] in contact with it; it penetrates the pores of the meat, and places one third or one half of the water the meat contained in a condition powerless for injury. It is more efficient in dry salting than in the condition of brine, a solution of salt, which still, however, preserves meats immersed in it. Beside merely absorbing moisture, it probably has some action on the muscular tissue, the nature of which is not understood. It certainly dissolves and removes much of the nutriment contained in the juice of the meat, and thus causes a considerable loss. Sugar has the same property with salt of taking up the moisture from bodies, and is an important agent in some processes of preserving food. Choice fish, as salmon, are sometimes kept by rubbing in sugar and afterward drying, and hams of superior quality are thus known as "sugar-cured." Sirups are produced with the juices of fruits which are boiled with sugar, and if these sirups are strongly saccharine they are little liable to undergo change. Saltpetre possesses the drying property in a [illegible] degree than salt or sugar. It is often used with salt, probably for the sake of the reddening action it has upon the animal fibre, thus correcting the somewhat bleaching property of salt. Smoking, which is another important method of preserving meats, is efficient in part from the drying action of the heat, and in part from the antiseptic properties of the pyroligneous acid and creosote generated in the [illegible] combustion of the wood fuel. Some woods impart a peculiar flavor to the smoked meats which is not always objectionable. Westphalia hams are thus flavored by the juniper wood with which they are smoked. Care is necessary in smoking as well as in drying meat to prevent the temperature from exceeding [illegible] F., the effect of greater heat being to coagulate the albumen and render it insoluble and innutritious. For some articles of food this is not objectionable, and vinegar is used as a powerful preservative, its action being exerted to render the albumen (the ingredient most ready to undergo putrefactive fermentation) inert and consequently indigestible. But the articles thus preserved, as pickles, &c., are esteemed rather as appetizers than for the nutriment they afford. Low temperature is a perfect protection against changes in organic compounds. At the freezing point the juices are fixed by congelation; and at several degrees above their elements are little disposed to change. At the extreme cold of high latitudes animal substances may be kept for indefinite periods, as was exemplified in a wonderful manner by the discovery in 1779 of the extinct species of elephant in the ice of northern Siberia, the flesh of which was unchanged, and served for the food of wolves. The markets of northern countries are often supplied with frozen meats

d fish brought from distant places, and kept
r a long time. Supplies of beef and pork at
ke Superior, instead of being "put down"
the autumn, are commonly hung up as the
nimals are killed, and at any time during the
inter fresh meat is cut from the pieces.
evere frost is injurious to the flavor; but a
gular temperature at or a little above the
eezing point is effectual to preserve meats
ithout impairing their good qualities. After
eing frozen the thawing should be gradual, or
udden putrefaction is likely to ensue. Vege-
ables and fruits are best preserved in large
uantities in dry places where the temperature
uniformly low, but above freezing; as in cool
ry cellars, and caves specially made for this
rpose in dry sand banks. The introduction
f refrigerators, or ice boxes, in markets and
rivate houses, effects an immense saving in the
reservation of meats from decay.—Common
ir, or oxygen, is as essential to the decay of
rganic bodies as moisture; hence, if it is ex-
luded, they are preserved. Fruits are pro-
ected by their natural skin; but if this is in-
jured, the exposed part is soon affected by the
xygen of the air, and decay goes on from this
oint. Once begun, it is not arrested, though
he air be then excluded. Grapes may be long
reserved carefully packed in saw dust, but the
uncture of the skin of one of them with a
eedle will soon be followed by fermentation.
ence the importance of carefully handling
ruits intended to be kept a long time. Fer-
entation is checked by boiling, and the air
eing then excluded, the articles may still be
reserved. On this principle the most efficient
lans of preserving food in their original con-
ition are founded. M. Appert received in 1810
rom the French government 12,000 francs for
ntroducing his process of parboiling provisions
and then confining them in air-tight jars. His
ethod was perfected by Donkin and co. and
amble of London, and as thus improved is
ow in common use. It has proved of immense
mportance for navy and army supplies, and is
pecially valuable for furnishing fresh meats on
ong voyages. Alimentary substances of almost
ny kind are cooked in the usual way; from the
eats the bones are removed, and they are then
ut in tin canisters with or without vegetables,
nd the canister is immediately filled quite full
with rich gravy. A cover with a small hole
n it is then fitted on, and the vessel is set in
oiling water, or in a hotter saline solution.
he heat expels all the air that may be in the
anister, and steam also issues through the
ittle aperture. This is checked by the appli-
ation of a damp sponge, when the hole is in-
tantly stopped by soldering, and it is exposed
gain to a boiling temperature. As the con-
ents cool they contract, and the cover is bent
a little in by the external pressure of the air.
If afterward, on being exposed to a tempera-
ure of 100° F., putrefaction does not take place
nd burst the canister, no free oxygen is pres-
ent, and there is no risk of the contents spoiling in any climate for any length of time. By a later improvement the air is partially exhausted from the canister while it is standing in hot water, and it is then immediately closed. Cans and bottles are now provided and largely used for preserving fruits, having metallic covers that screw tightly down, and the joint is made still more secure by the application of wax. The fruits are preserved either with or without sugar; and if without, a gill of water is introduced into the can for every quart of fruit. In every case the can is set into boiling water for 15 to 20 minutes before the cover is tightly screwed down, and after this for about half as long. The second boiling is designed to convert any oxygen that may possibly remain in the can into carbonic acid. In Texas a very nutritive and portable food called meat biscuit has been prepared by mixing strong beef broth with flour and baking. This may be cheaply produced in large quantities wherever cattle are destroyed for the sake of their skins only. Methods of preserving milk and butter are given in the articles on those subjects.

PRESERVATION OF WOOD. Under the head of DRY ROT, one of the principal causes of the decay of wood has been considered, and reference was made to some of the methods of preserving wood. The protection of timber from decay is a subject which for some time has been attracting much attention in Great Britain, especially in reference to the use of the timber in ship building, and also in the construction of railroads, the substructure of which consists of wooden sleepers partially buried in the ground, and consequently under the most favorable conditions for rapid decay; and in the United States it is of great importance for the same applications. The methods in use are various, but are generally based upon the principle of expelling the natural juices of the wood and filling the pores with some substance possessing antiseptic properties, that will coagulate the remaining albumen, or that will prevent the admission of moisture. In the petroleum districts of Burmah and the Caspian sea, the quality of the natural rock oil to preserve timber that has been immersed in it is well understood, and the inhabitants employ the article for this purpose. The timber of whale ships is more durable for the oil it imbibes, and the staves of old oil casks are little liable to decay. If timber is well steamed in large tanks and the temperature is suddenly lowered, the pores are freed from the fluids and soluble matters in the wood, and are thus better prepared for the absorption of oil or other preservative liquids. In England no fewer than 47 patents have been granted for processes designed "to preserve animal and vegetable substances, including timber," 4 only of which were in the last century, the earliest in 1737. The first that was extensively applied was the process of Mr. Kyan, patented in England in 1832, and some time afterward introduced into the United States by the inventor.

The wood was immersed in a solution of corrosive sublimate till saturated with it; and if it were necessary to hasten the process, this was done by employing an air-tight tank, exhausting the air, and forcing in the solution by external pressure. When faithfully conducted the effects were perfectly satisfactory; but, except by the use of open tanks, which was an extremely tedious method, the difficulties encountered in the employment of so corrosive a salt, together with the great cost of the material and the introduction of new methods, led to the abandonment of what was known as the kyanizing process.—Of the various preparations now used in England, that of Mr. J. Bethel, consisting of the oily mixtures obtained by a rough distillation of the tarry liquor of gas works, appears to be regarded as the most efficient. A solution of pyrolignate of iron is also similarly effective. From the presence of creosote in these liquors, and its known antiseptic property, the process is called creosotizing. The wood is put into a close tank, from which the air is exhausted, and the operation of the air pumps is continued several hours. The liquid is then admitted, and pressure is applied to the amount of 150 lbs. to the square inch; and this is kept up by continual pumping for 48 hours or longer. Yellow pine is thus increased in weight 11 lbs. to the cubic foot, and Riga pine about 8 lbs. The process is adopted by a large proportion of the railroad companies of England for the preservation of the sleepers, and, notwithstanding its somewhat expensive character, is highly approved of. Timber thus prepared retains a disagreeable smell, which for shipbuilding purposes is objectionable. It is also more inflammable than before. Insects will not attack it, and the preparation is a perfect protection against the *teredo navalis* or ship worm. The fibre of the wood is not only protected from moisture and the destructive action of alternating conditions of dryness and moisture, but it is greatly strengthened, so that the most porous and cheapest sorts of wood may be used for purposes commonly requiring strong oak.—In France the process of Dr. Boucherie has been extensively employed for railway and ship timber. The material used is sulphate of copper (blue vitriol) dissolved in 100 parts of water, so that at 60° F. the density is about 1.006. The timber set on end is covered with a water-tight cap, into which the solution is conveyed through a flexible tube from the tank placed at an elevation of 30 or 40 feet. The sap is first forced out at the lower end by the pressure, and when it is exhausted the copper solution follows and occupies its place. Some kinds of timber are not penetrated by the solution; but it is perfectly effective in filling the pores of beech, birch, larch, Scotch fir, alder, elm, poplar, &c. The time required to complete the operation depends on the kind of wood and the length of the sticks. Timber thus prepared at Fontainebleau for the French navy was fully impregnated in 24 hours in lengths of 9 feet; but sticks of the same timber 40 feet long required 10 days for the completion of the process. Trees felled at any time between May and November were treated within 3 weeks of the time of felling; but if felled between November and May they were kept till the [illegible] month. Sulphate of copper, and the [illegible] also, had been applied in England by [illegible] and used to a considerable extent; so that the novelty in Dr. Boucherie's process is the peculiar and inexpensive method of injecting the solution. It is still extensively practised for preparing sleepers and telegraph posts for the French railways.—Another process also employed in England, and more especially in France, is that of Mr. Payne, patented in England in 1841. The timber is introduced into a long iron cylinder, which is then closed air-tight. Steam is driven in, expelling the air through a valve opened for the purpose, and a cold solution of sulphate of iron (green vitriol) is pumped in, which condenses the steam and produces a partial vacuum. This is made more complete by the air pump, and the cylinder is then filled with the solution, which is still forced in under considerable pressure. In a few minutes the solution is let out and the cylinder is again filled with air. This is again expelled by steam, and a solution of another salt is admitted, of such character as will react upon the sulphate of iron, producing double decomposition and leaving in the pores of the wood an insoluble salt. Chloride of lime answers this purpose, and the insoluble sulphate of lime remains in the wood, the hydrochlorate of iron being absorbed or washed out. Several other salts may be substituted for the lime salt, and among these carbonate of soda has been advantageously employed.—In the United States the process preferred to all the others is that called burnettizing, consisting in the use of chloride of zinc. For this a patent was granted in England in 1838 to Sir William Burnett, but the process was never patented in America. It was first introduced at Lowell, Mass., where in 1850 the "proprietors of the locks and canals on Merrimack river," at the joint expense of the manufacturing companies, erected an apparatus for carrying it on. The works proved so successful and capacious that a regular business was established, and lumber of various sorts has been submitted to the process for railroad companies and other parties at an expense of $5 to $6 per 1,000 feet, board measure. The cylinder in which the operation is conducted is of cast iron, 60 feet long and 5 feet in diameter, with one head movable, the iron [illegible] an inch thick. A rail track of 2 feet gauge leads into the cylinder, and upon this the timber, loaded and chained down upon a heavy low truck, is run in by steam power, the charge amounting to about 7,000 feet. The cylinder head being closed and packed, the air is exhausted by an air pump of 12 inches diameter and 8 feet stroke, and a vacuum is maintained of about 28 inches of mercury, this operation lasting in all about 45 minutes. The pumps are then changed and the cylinder is filled by atmospheric pressure from a large cistern containing a solution of 100 parts of water and 1½ parts of dry chloride of zinc by weight, and the pressure is raised to 125 lbs. to the square inch above the atmospheric pressure. To do this occupies 20 minutes, and the pressure is maintained 2½ hours longer. The surplus solution is then drained off into the cistern, for which 1½ hours are allowed; the cylinder head is then unlocked, and the truck with its load drawn out. The whole time occupied, including the loading and unloading, is 7 hours and 20 minutes. To produce the best results, the charge should consist of timber of uniform thickness, as otherwise the thicker blocks are not saturated throughout when the thinner have absorbed more than is necessary. The wood should not be seasoned, as it then absorbs the solution with greater difficulty, and the inner portions, even of plank and other stuff of moderate dimensions, may not be reached by the solution at all. Of the concentrated solution as received from the manufacturers, containing about 25 per cent. of the dry chloride, from 10 to 40 lbs. are taken up by 1,000 feet, board measure, or from about 2 to 8 ounces to a cubic foot. A method of burnettizing wood in open tanks, thus saving the expense of the costly apparatus now employed, is proposed by F. Hewson, C.E., in the "Journal of the Franklin Institute" for Jan. 1859.—Lime water has been recently employed in England for preserving wood, the timber being allowed to soak in tanks containing it. The lime is said to penetrate the pores of the wood, neutralizing the albuminous and saccharine principles. As the hydrate of lime changes after a time to the carbonate, the pores become filled with the stony product, and the effect is that of incipient petrifaction.

PRESIDENT (Lat. *præses*), an officer appointed or elected to preside over a tribunal, a company, an assembly, or a republic. The chief executive officer of the United States bears this title, and the second executive officer, the vice-president, is by virtue of his office the president of the senate, and succeeds to the office of president of the United States on the death or disability of the regular incumbent during his term. The chief executives of Mexico and the republics of Central and South America are also termed presidents. The president of the United States holds his office for the term of 4 years, beginning on the 4th day of March next succeeding the day of his election. He is chosen by electors who are themselves chosen by the people, and he must be a native of the United States and at least 35 years old. His powers are thus fixed by the constitution of the United States, article ii. section 2: "The president shall be commander-in-chief of the army and navy of the United States, and of the militia of the several states when called into the actual service of the United States; he may require the opinion in writing of the principal officer in each of the executive departments, upon any subject relating to the duties of their respective offices, and he shall have power to grant reprieves and pardons for offences against the United States, except in cases of impeachment. He shall have power, by and with the consent of the senate, to make treaties, provided two thirds of the senators present concur; and he shall nominate, and, by and with the advice and consent of the senate, shall appoint ambassadors, other public ministers and consuls, judges of the supreme court, and all other officers of the United States, whose appointments are not herein otherwise provided for, and which shall be established by law; but the congress may by law vest the appointment of such inferior officers as they may think proper in the president alone, in the courts of law, or in the heads of departments. The president shall have power to fill up all vacancies that may happen during the recess of the senate, by granting commissions which shall expire at the end of their next session." Section 7 of article i. requires that every bill which passes congress must have the president's signature to become a law, unless, after he has returned it to congress with his objections, two thirds of each house shall vote in its favor. The president's duties, as determined by article ii. section 3, are to give to congress from time to time information of the state of the Union, and recommend to their consideration such measures as he shall judge necessary and expedient; to convene both houses on extraordinary occasions, and, in case of disagreement between them as to the time of adjournment, to adjourn them to such time as he shall think proper; to receive ambassadors and other public ministers; to take care that the laws be faithfully executed; and to commission all the officers of the United States. He can be removed from office on impeachment for and conviction of treason, bribery, or other high crimes and misdemeanors. The presidents of the United States from the adoption of the constitution till the present time have been 16 in number, viz.: George Washington (inaugurated April 30, 1789), John Adams, Thomas Jefferson, James Madison, James Monroe, John Quincy Adams, Andrew Jackson, Martin Van Buren, William Henry Harrison, John Tyler, James Knox Polk, Zachary Taylor, Millard Fillmore, Franklin Pierce, James Buchanan, and Abraham Lincoln (inaugurated March 4, 1861). Of these, five served two terms each, viz.: Washington, Jefferson, Madison, Monroe, and Jackson; two died while in office, viz.: Harrison (April 4, 1841, one month after his inauguration) and Taylor (July 9, 1850, 16 months after inauguration); and the two who succeeded the last mentioned, Tyler and Fillmore, were elected as vice-presidents.

PRESS, Printing. See Printing.

PRESTER JOHN, the name given by Europeans in the middle ages to a supposed Christian sovereign or dynasty of sovereigns established in the interior of Asia. The name of this personage occurs first in the 11th century, and according to one account he was an eastern potentate dwelling beyond Persia, who, having been converted to Christianity by the spirit of a departed saint, caused his subjects to adopt the same faith. He was at once sovereign and priest of his people (whence his name Prester or Presbyter), and his sway, in its pastoral simplicity and benignity, was compared to that of kings in the patriarchal times. This story was subsequently found to be a mere Utopian fancy. The belief in the existence of Prester John, however, took a more tangible shape in the 13th century, and on the authority of some Nestorian priests he was said to be identical with Ung Khan, a powerful Tartar chief living in Karakorum, in eastern Tartary, who in 1202 was overthrown and slain by Genghis Khan. Giovanni Carpini, a Franciscan friar, who in 1246 was sent on a mission to Batoo Khan, the grandson of Genghis, failed to discover the Christian monarch or his subjects, but supposed him to be established further to the eastward. A few years later another Franciscan, Rubruquis, penetrated as far as the court of Batoo Khan in central Tartary, and was thence forwarded to Karakorum, the residence of Mangoo Khan, and the supposed seat of Prester John. His search for the latter was unavailing, but from a few Nestorian priests whom he met there, he ascertained that Ung Khan had encouraged the propagation of Christianity in his dominions. The existence of Prester John nevertheless continued to be believed, and as late as the close of the 15th century the Portuguese, who had reached India by the way of the cape of Good Hope, made fruitless inquiries for him there. About the same time Peres da Covilham, a Portuguese traveller, made a journey to Abyssinia in quest of the kingdom of Prester John; and finding the *negus* or king of Habesh to be a Christian prince, he conferred the title upon him, although it had never been claimed by that monarch. Mosheim, in his "Ecclesiastical Institutes," conjectures that Prester John may have been a Nestorian priest, who, gaining possession of a throne in eastern Tartary, transmitted his title as well as his name to his successors. Others have supposed him to be identical with the grand lama.

PRESTON, a N. W. co. of Va., bordering on Pennsylvania and Maryland, and intersected by Cheat river; area, about 600 sq. m.; pop. in 1860, 13,312, of whom 67 were slaves. It occupies a valley between the Chestnut ridge on the W. and the Alleghany ridge on the E., and the soil is very fertile. Iron ore, coal, sandstone, and slate are found, and extensive water power is afforded by the streams. The productions in 1850 were 144,276 bushels of Indian corn, 153,496 of oats, 36,769 of wheat, 7,765 tons of hay, 43,970 lbs. of wool, and 179,836 of butter. There were 4 tanneries, 1 woollen factory, 28 churches, and 840 pupils in public schools. Value of real estate in 1860, $2,980,604, showing an increase since 1850 of 155 per cent. It is traversed by the Baltimore and Ohio railroad. Capital, Kingwood.

PRESTON, a town of Lancashire, England, on the right bank of the river Ribble, 210 m. by railway N. W. from London; pop. in 1861, 69,542. It occupies an eminence rising from the river. A handsome railway viaduct feet high, spans the river. The staple manufacture of Preston was originally linen, which is still made to some extent, but has been completely eclipsed by cotton. There are more than 50 cotton mills, beside manufactories of worsted, machinery, &c. Vessels of 300 tons can ascend to the quays. Preston owes its name, originally Priests' Town, to the number of religious houses it contained. It returns members to parliament.

PRESTON. I. **William Campbell**, an American statesman and orator, born in Philadelphia, Dec. 27, 1794, died in Columbia, S. C., May 22, 1860. He was of a Virginia family, and his paternal grandfather, who married a sister of Patrick Henry, participated in the war of independence as colonel in the forces of that commonwealth. His own birth happened in Philadelphia during the temporary residence of his father there as a member of congress. In his 14th year he was sent to college at Lexington, Va., but being compelled by ill health to visit the South, he finished his education at the state college in Columbia, S. C., where he was graduated in 1812. Returning to Virginia, he commenced the study of the law with William Wirt, but after a few months was again compelled to travel for the benefit of his health. After an extensive tour through the valley of the Mississippi, he visited Europe, where he remained several years, and at the university of Edinburgh pursued his studies under Professors Playfair, Brown, and Irving. In 1819 he returned to Virginia, and in 1820 was admitted to the bar of that state. Two years afterward he transferred his residence to Columbia, S. C., and soon gained a reputation as a public speaker. In 1828, and again in 1830–'32, he was returned to the state legislature, and became one of the leaders of the nullification party. In 1836 he was elected to the U. S. senate; but differing with his colleague, Mr. Calhoun, and his constituents in regard to the support which they gave to Mr. Van Buren, he resigned his seat and resumed the practice of the law. He was thus engaged when in 1845 he was induced to accept the presidency of the South Carolina college. The institution had sunk somewhat in public esteem on account of the supposed lax views of religion entertained by its former president, Judge Cooper; and notwithstanding new professors had been introduced, and other reforms adopted by the trustees, the students were ill disciplined and frequently in open rebellion. On Mr. Preston's assumption of authority the college soon rose to a degree of prosperity un-own before. He held the office until 1851, en declining years and health prompted his tirement. He soon after established the Co-umbia lyceum, which he endowed with his rary, containing 3,000 selected volumes. As orator and a lawyer he held a distinguished ace among the public men of South Carolina, though his reputation in the former capacity terfered with his success at the bar. Judge 'Neall, in his "Bench and Bar of South Caro-na," testifies to his great abilities as a *nisi prius* wyer, and asserts that "his circuit speeches, pecially in criminal cases, were unsurpassed." is style was ornate and florid, his elocution raceful, and in his more elaborate productions e evinced a considerable knowledge of Eng-sh classical literature. II. JOHN S., brother f the preceding, born near Abingdon, Va., pril 20, 1809. He was educated at Hampden idney college and the university of Virginia, nd subsequently studied in the law school of arvard university. In 1830 he married a aughter of Gen. Wade Hampton of South Car-lina, and during the political excitement of hat period became an active nullifier. For a umber of years subsequent he was chiefly oc-upied with sugar planting in Louisiana, where e owned large estates, although he still re-ained his residence in Columbia, S. C. From 848 to 1856 he was a member of the South Carolina legislature, where he gained considerable reputation as an orator; and during the ame period he became more widely known in this capacity by addresses before the '76 association of Charleston, the literary societies of the South Carolina college, and particularly at the celebration of the 75th anniversary of the battle of King's Mountain, which was attended by 15,000 persons from North and South Carolina, Virginia, and Tennessee. From 1856 to 1860 he resided chiefly abroad, superintending the education of his children, and in 1860 he was elected a delegate to the national democratic convention which met in Charleston in May of that year to nominate a candidate for the presidency, and in which he acted as chairman of the South Carolina delegation. Subsequently he withdrew with his associates from the convention, and was not again a delegate. His course in participating in the proceedings of the convention at all, under the peculiar relations which South Carolina then sustained to such bodies, subjected him to severe censure; but having promptly joined the secession movement after the election of Mr. Lincoln, he was appointed a commissioner to Virginia, and upon presenting his credentials to the convention of that state in Feb. 1861, made an elaborate plea in favor of her immediate withdrawal from the Union, which is esteemed the crowning effort of his oratory. He has since occupied himself almost exclusively with his private business.

PRESTON PANS, a village in Haddingtonshire, Scotland, on the frith of Forth, 8½ m. E. of Edinburgh, where was fought a memorable action between the Scottish Jacobites under the Young Pretender and the royal troops under Sir John Cope, Sept. 21, 1745. The opposing armies came within sight of each other on the afternoon of the 20th, Cope occupying a strong position adjoining the village of Preston Pans, and having his front protected by a deep morass, while the pretender's troops, consisting mostly of highlanders, were posted on a ridge about a mile distant. The armies were nearly equal in numbers, the royalists having about 2,200 men, with 6 pieces of artillery, and the insurgents 2,500; but in appointments and discipline the former had decidedly the advantage, the highlanders being a hastily gathered rabble, without artillery or cavalry, indiscriminately armed with muskets, broadswords, scythes, or Lochaber axes, and kept together chiefly by enthusiasm for their cause and the expectation of plunder. Cope was urged to commence the engagement at once, instead of allowing the spirits of his men to be damped by remaining on the defensive, but declined; and at nightfall both armies lay in sight of each other. At midnight the pretender was informed that a path leading to the plain below and avoiding the morass had been discovered, and at a council of chiefs immediately summoned, it was determined to march at once to the attack. Under cover of the darkness and of a heavy mist the clans reached the plain in safety, where Cope's forces, alarmed by the firing of their outposts, were drawn up to receive them, the infantry occupying the centre, and either wing being protected by a regiment of dragoons, in front of one of which, Gardiner's, was the artillery. As the sun rose, the highlanders, who were formed in 2 lines, the 2d of which was led by the pretender, uncovered, and having uttered a short prayer, rushed with a terrific yell upon their enemy. The artillery, which was badly served by seamen collected from the fleet, instead of by regular gunners, was in a moment overpowered; and the dragoons in their rear, panic-stricken by the fierce shouts and the impetuous courage of their opponents, who, discarding their muskets after a single volley, threw themselves broadsword in hand upon the very muzzles of the guns, galloped away in all directions, heedless of the exhortations of their commander, Col. Gardiner. The other regiment of dragoons was scattered with equal rapidity, and the infantry, uncovered at both flanks, were, after a brief though brave resistance, completely routed. "So rapid was this highland onset," says Lord Mahon, "that in 5 or 6 minutes the whole brunt of the battle was over." Nearly all the royal infantry were killed or taken prisoners; but the dragoons, owing to the lack of troopers in the pretender's army, mostly escaped. Cope himself headed the fugitives, and scarcely drew rein until safe behind the walls of Berwick, where Lord Mark Kerr, the commandant, congratulated him upon being the first general on record who had carried the tidings of his own defeat. The humorous Scotch ballad, "Johnnie Cope," was suggested by the precipitate flight of the English general. Of the royal army nearly 400 were slain, including Col. Gardiner, a man of great worth and gallantry, who, after the flight of his dragoons, put himself at the head of a small party of infantry and was cut down by a highlander armed with a scythe. His life and character form the subject of a memoir by his friend Dr. Doddridge. The pretender lost about 100 men killed and wounded. The battle was called by the Jacobites that of Gladsmuir, out of respect to a passage in a book of prophecies printed in Edinburgh in 1615: "On Gladsmuir shall the battle be," although that place is a mile distant from the field of conflict. On the following day the pretender made a triumphal entry into Edinburgh, the pipers playing the old cavalier tune: "The king shall enjoy his own again."

PRESUMPTION, in law, an inference or assumption which the law makes in the absence of evidence. Presumptions are divisible into conclusive presumptions and disputable presumptions. Conclusive presumptions answer to the *præsumptio juris et de jure* of the civil law. The law asserts them to be true, and will not permit evidence to deny or refute them. A familiar illustration may be found in the rule that a debt which has run 20 years, whether under seal, or by judgment, or resting on other evidence, is conclusively presumed to have been paid. If it be sued one day before the 20 years expire, the creditor need only prove the debt, and the debtor must prove that he has in some way satisfied it. But if it be sued one day later, not only is the debtor relieved from the necessity of proving payment, but the creditor will not be permitted to prove that the debt has not been paid. If the creditor can prove any thing which the law would recognize as a new promise within 20 years, the suit may be maintained on this new promise, but the old debt is conclusively settled. Another common instance is the rule in respect to land, possession of which under a claim of absolute ownership for a certain period constitutes a conclusive presumption of a valid grant, which cannot be disturbed by evidence. This period is now, in the United States, generally 20 years; but in some it is much less, and in others extends to a longer period. (See PRESCRIPTION.) These presumptions rested originally on the probability that they were true, but came at last to stand upon the ground that the peace of society and the possession of property should be protected against stale claims, which, after being suffered to sleep so long, cannot be revived and prosecuted without working an injury. The presumptions arising under all the statutes of limitation may be considered as of this class; and we have already stated the general principles applicable to these presumptions, and the way in which, from being regarded as statutes founded on probability, they came to be considered and treated as statutes of repose. (See LIMITATION, STATUTES OF.)—Conclusive presumptions are not very common in the law. But disputable or rebuttable presumptions, answering to the *præsumptio juris* of the civil law, constantly occur. They are indeed no more than legal inferences from existing evidence, open to modification or reversal by further evidence. They are much the same as *prima facie* conclusions or inferences; as, for example, when one sues a promissory note and proves his own possession and the signature of the maker, the law presumes the plaintiff to be the owner of the note, and also presumes consideration, and gives the plaintiff his case, unless the defendant overcomes the presumption by evidence on his part of some ground of defence. The general presumption of innocence in favor of an alleged criminal, and of absence of debt in favor of a defendant in a civil suit, are of this kind. It will be seen therefore that disputable presumptions do no more than determine where the burden of proof rests.

PRETENDER, an epithet applied to the eldest son and grandson of James II., who laid claim to the throne of England. (See JAMES FRANCIS EDWARD STUART, and CHARLES EDWARD.)

PRÉVILLE, the assumed name of PIERRE LOUIS DUBUS, a French comedian, born in Paris in 1721, died in Beauvais, Dec. 18, 1799. After having performed at many provincial theatres, he appeared at the *théâtre Français* in Paris in 1753, and was the favorite of the Parisian public for 33 years. His best parts were Sosia in Molière's *Amphitryon*, Turcaret in Le Sage's comedy of that name, La Rissole in Boursault's *Mercure galant*, and Figaro in Beaumarchais's *Barbier de Séville* and *Mariage de Figaro*. From memoranda which he left, M. Cahaisse composed his *Mémoires* (Paris, 1813).

PRÉVOST D'EXILES, ANTOINE FRANÇOIS, a French novelist, born at Hesdin, Artois, April 1, 1697, died near Chantilly, Nov. 23, 1763. He was intended for the church and educated at a Jesuit college, but in his 16th year entered the army. Soon returning to the college, in a few months he ran away again, and for 4 or 5 years led a very dissipated life. At the age of 22 he sought admission among the Benedictines of St. Maur, took the vows in 1721, was ordained priest, and proved a successful preacher. Being sent to the abbey of St. Germain des Prés, he shared in the historical and literary labors of the learned monks, and in the meantime diverted his mind by writing novels. Unable to support the austerities of the convent, he desired to be removed to a less severe branch of the same order; but the issuing of the brief of translation which had been granted to him by the pope being unaccountably delayed, he abandoned the order altogether in 1728, and went to Holland, where he supported himself by his pen. Having published *Mémoires d'un homme de qualité* (6 vols. 12mo., 1729), he went to England, where he published *Cleveland* (6 vols. 12mo., 1732), and *L'histoire de Manon*

caut et du chevalier des Grieux (1733). The
named work is supposed to be a slightly
guised account of the author's own experience,
ranks as one of the best of French novels.
1754 he was permitted to return to France
appointed almoner to the prince of Conti.
now wrote *Le doyen de Killerine* (6 vols.,
40), published a French translation of Cicero's
ters Ad Familiares (1745), undertook a *His-*
re générale des voyages, which he carried for-
ed to the 80th volume, and translated into
nch Richardson's "Pamela," "Clarissa Har-
ve," and "Sir Charles Grandison." In his
er years he led a quiet religious life at St.
ymle, near Chantilly. Having fallen in a fit
apoplexy, he was supposed to be dead, and
topsy was ordered. The first stroke of the
ife restored him to consciousness, but it had
licted a mortal wound. His complete works
prise more than 170 volumes. His *Œuvres*
isies were published in 39 vols. 8vo. (Paris,
83–'5), and reprinted in 1810, with illustra-
ns. The *Histoire générale des voyages* was
ridged and continued by La Harpe.

RIAM, the last king of Troy, and according
he legend 5th in descent from Jupiter. He
s the son of Laomedon, and in his youth was
en prisoner by Hercules. Previous to this
had been called Podarces, the swift-footed;
he was now bought from Hercules by his
er Hesione, and was thence called Priamus,
the ransomed. According to Homer he had
children, Hecuba alone having borne him
; among them were Hector, Paris, Helenus,
iphobus, Polyxena, Cassandra, and Creusa.
ring the sack of Troy by the Greeks he was
in at the foot of an altar by Pyrrhus.

PRIAPUS, in Greek and Roman mythology,
type of fecundity, son of Bacchus and Venus.
cording to different Greek and Roman poets,
was the son of Bacchus and a Naiad, or of
lonis and Venus, or of Mercury or of Pan.
e was generally represented in the form of
rms, or a head placed on a quadrangular pil-
r, and painted red. His emblem was the
allus, and bearing this his image was placed
gardens and vineyards.

PRICE, Richard, an English divine and
oralist, born in Tynton, Glamorganshire, Feb.
, 1723, died in London, April 19, 1791. The
n of a dissenting Calvinistic minister, he
as educated under private clerical tuition,
d in his 18th year he went to London to
mplete his preparation for the ministry.
s uncle obtained for him admission into a
senting academy, where for 4 years he
udied mathematics, philosophy, and theology.
1743 he became domestic chaplain to Mr.
eathfield of Stoke Newington, in which
ice he remained 13 years, at the same time
eaching occasionally. The death of his uncle
t him a small fortune, and he married in
57, and became morning preacher in New-
ton Green chapel. He was afterward ap-
inted pastor of the Gravelpit meeting, Hack-
y, and afternoon preacher at Newington Green, both of which offices he resigned a short time before his death. In 1757 he published his "Review of the Principal Questions and Difficulties in Morals," an attempt to found moral obligation on intellectual instead of sentimental tests. Reason alone, he says, did we possess it in a higher degree, would answer all the ends of the passions. In 1769 he published a treatise on reversionary payments, drawing attention to the defective principles adopted by several societies designed to secure annuities to surviving widows, which resulted in their dissolution or modification; the 5th edition appeared in 1803. He published in 1776 his "Observations on Civil Liberty and the Justice and Policy of the War with America," of which 60,000 copies were soon distributed. The American congress afterward invited him, through their commissioners, to become a citizen of the United States, and to aid them in managing their finances, promising him a liberal remuneration if he should remove to America. He declined the request, at the same time speaking of the United States as the hope and the future refuge of mankind. He was an admirer of Plato, and a firm believer in the immateriality of the soul. He is the author of various works on religion, ethics, politics, and finance. His biography was written by William Morgan, D.D. (London, 1815).

PRICE, Sir Uvedale, an English writer on landscape gardening, born in 1747, died in Foxley, Herefordshire, Sept. 11, 1829. He was educated at Oxford, and in 1780 first appeared in print as the translator of Pausanias, in a work entitled "An Account of the Statues, Pictures, and Temples in Greece." His fame rests chiefly upon his "Essay on the Picturesque, as compared with the Sublime and Beautiful, and on the Use of studying Pictures for the purpose of improving Real Landscapes" (1794), which brought him into conflict with Repton, then a prominent landscape gardener. To his criticism Price replied in 1795, in "A Letter to H. Repton, Esq., on the Application of the Practice as well as the Principles of Landscape Painting to Landscape Gardening." In 1828 he was made a baronet.

PRICHARD, James Cowles, M.D., an English ethnologist, born in Ross, Herefordshire, Feb. 11, 1786, died in London, Dec. 22, 1848. He was graduated M.D. at Edinburgh, and settled as a physician in Bristol in 1810, but devoted his leisure to ethnological studies. In 1813 he published his "Researches into the Physical History of Man," and in 1826 a second and greatly enlarged edition of it, in which he developed for the first time to its full extent the philological element in ethnology. In 1841 he was appointed inspector of lunatic asylums, and removed to London, where in 1847 he brought out the third edition of the "Researches" (5 vols. 8vo.), comprising the results of 37 years' study. He is also the author of various professional works, a *résumé* of his "Physical History," "Natural

History of Man" (2 vols., 1848), and what is called by Bunsen his most original contribution to science, "The Eastern Origin of the Celtic Nations" (London, 1831; new ed. by Latham). Dr. Prichard's position as an ethnologist was one of eminence in Europe; the same writer (Baron Bunsen) says of his great work: "Up to this time there exists no book which treats all subjects bearing on the great question of the unity of the human species with equal depth and candor, good sense, and sound judgment."

PRICKLY PEAR. See CACTUS.

PRIDE OF INDIA, PRIDE OF CHINA, or NEEM TREE (*melia azedarach*, natural order *meliaceæ*), a native of Syria, Persia, and the north of India, and cultivated in different parts of the world as an ornamental tree. It grows to the height of 30 or 40 feet with a trunk of 20 inches diameter; but in open spaces it is spreading and not so high. Its leaves consist of smooth, pointed, dark green leaflets, arranged in pairs with an odd one at the end. The flowers, hanging in clusters at the ends of the branches, are of lilac color and agreeable perfume. They give place to bunches of berries about as large as cherries, and yellow when ripe. The pericarp has afforded an oil for economical purposes. The fruit is sweetish, and is generally supposed to be poisonous, but it may be eaten with impunity. In the cities of the southern states and upon many of the plantations rows of pride of India trees are very common, and in the autumn the branches and the ground beneath are covered with their berries. The tree has some reputation for its medicinal virtues, and a decoction of the bark of the root is administered as a cathartic and emetic. It is considered in many places an excellent remedy for worms, and is much used for children. In large doses it is said to produce narcotic effects, and such appears to be the action of the ripe berries upon the robin redbreasts, which are very fond of them, and eat them until they become stupefied and fall to the ground. From this state however they soon recover.

PRIDEAUX, HUMPHREY, an English clergyman and author, born in Padstow, Cornwall, May 3, 1648, died Nov. 1, 1724. He was educated at Westminster under Dr. Busby, and at Christchurch, Oxford, and assisted Dr. Fell in preparing an edition of the historian Lucius Florus. Having been selected by the university to edit the inscriptions of the Arundelian marbles, he published them in 1676 after two years' labors, under the title of *Marmora Oxoniensia ex Arundellianis, Seldenianis, aliisque conflata, cum perpetuo Commentario.* In 1679 he was presented by Lord Chancellor Finch to the rectory of St. Clement's, Oxford, was appointed the same year Dr. Busby's Hebrew lecturer in Christchurch, and published two tracts of Maimonides in the original with a Latin translation and notes, under the title *De Jure Pauperis et Peregrini apud Judæos.* In 1681 he was made a prebendary of the ca dral of Norwich, where he had a contro with the Roman Catholics, which resul his publishing a book entitled "The Val the Orders of the Church of England ma He opposed James II. in his proceedings a the established church, and, having bee pointed to the archdeaconry of Suffolk after some hesitation the oath of allegia William and Mary. In 1696 he was ma car of Trowse, near Norwich, and in 17 of Norwich. He was the author of a of Mahomet" (1697), "Directions to C Wardens" (1707), and a work on "T (1710); but his last and greatest wor "The Connection of the History of the and New Testaments," which appeared parts in 1715 and 1717 (last ed., 1858).

PRIESSNITZ, VINCENZ, a German pe the founder of the water cure, born in G berg, Austrian Silesia, Oct. 4, 1799, died Nov. 28, 1851. His father was a farmer Vincenz, after receiving the rudiments education, was required to work on the It was through an accident which hap to him while thus engaged, that he was brought to employ the cure which he s quently systematized. He then studied cine, and opened his cold water establis at Gräfenberg in 1829. (See HYDROPATHY

PRIEST, a person set apart for the per ance of religious offices and ceremonies, a particular for the performance of sa History shows the priestly office to be coextensive with religion itself, and har barbarous tribe has been discovered wit some sort of priests to guide the people in worship of their deity. The Old Tes contains but little information concerni exercise of priestly functions before the p gation of the law of Moses. We read tha and Abel offered their own sacrifices; seems that the priestly office soon came exercised by the heads of families onl Abraham, Isaac, Jacob, and Job. The priest, however, is not used respecting them; it occurs only once in the book of Ge when Melchisedek is called a priest of the High, but nothing is added to define the na of his priesthood. The Mosaic law estab a special priesthood consisting of three the high priests, the priests, and the Le all of them taken from one tribe, that of L The priesthood was made hereditary in family of Aaron; and the first born of th est branch of that family, if he had no blemish, was always the high priest. Th pointment was observed till the Jews fell the dominion of the Syrian Greeks, and their faith corrupted; then and afterward the Romans the high priesthood was some put up to sale, and became a temporary In the time of David the inferior priests w divided into 24 companies, serving in rota each company by itself for a week.—The history of the priesthood of the several religions is still involved in great obscurity, though elucidated in many important details by modern criticism. With most of the uncivilized tribes the priest had a very limited sphere of action; he generally appears as a sorcerer, who derives by communication with a spirit world the command of magic powers for the relief of the distressed and suffering. With some tribes the power of sorcery seems to have been the only attribute of the priesthood; with others they were also clothed with the office of divining, and with that of offering sacrifices. In the Society islands and New Zealand the priesthood formed a hereditary corporation; but nowhere among pagan tribes have they been so powerful and numerous as in Mexico, where they are said to have numbered 4,000,000 at the arrival of the Spaniards. —The idea of priesthood was much more fully developed by Brahminism. The Brahmins have assigned to them the primacy of honor among the 4 castes, and it is easy to trace in the enormous prerogatives with which they are clothed the fundamental idea of a vicegerency of God upon earth, for the purpose of conveying to mankind the divine blessings. Brahmins are also charged with preserving the soundness of doctrine, and with presiding over sacrifices and divine services.—The rationalistic state church of China, which owes its final organization to Confucius, has no special priesthood, but the priestly functions are blended with those of the emperor and the subordinate state officers. The Buddhist priests, called lamas in Mongolia and Thibet, bonzes in Japan, rahans in Burmah, talapoins in Siam, and gunnis in Ceylon, are essentially spiritual guides. They are to be examples of a perfect life, consisting, according to Buddhist views, in overcoming matter, accumulating merits, and thus preparing for a higher second birth. They do not form a caste; they live in celibacy, and their chief, the dalai lama, is regarded as the incarnation of Buddha himself. (See LAMAISM.) The magi of the Persians were the conductors of religious services and the teachers of the people. In Egypt the priests likewise formed one of the supreme castes, endowed with many privileges, and in particular exempted from paying taxes. Being divided into several classes, they constituted a complete hierarchy, on a democratic basis, with a chief priest, Pyromis, at their head. More than any other pagan priesthood, they distinguished themselves as the teachers and educators of the people, and secured the continuance of their prerogatives by keeping up their literary superiority. The ancient religion of the Greeks had no general priesthood, but only priests of the several deities, who slaughtered the victims, and often secured a powerful influence as the interpreters of the will of the deity which they served. Finally the priestly office among them fell into utter insignificance. The Roman priesthood was to a larger extent than that of any other great nation of antiquity charged with the office of divining. It was a well organized and largely privileged state institution, which knew how to retain its social position and political influence, when the belief in its faculty of divining had entirely ceased among the educated classes, and when, as Cicero says, he wondered how two augurs could meet without laughing at each other.—In the Christian system the gospel represents Christ as the one priest, who, for the redemption of the world, offered the one sacrifice, that of the cross. So far all who receive the record of the gospel as infallibly true agree; but there is a fundamental difference of opinion on the question, whether this sole priesthood of Christ is or is not incompatible with the existence of a proper priestly office in the church. The Roman Catholic church, and those eastern churches (Greek, Armenian, Nestorian, Jacobite, Coptic, Abyssinian) which regard ordination as a true sacrament, maintain that the sacrifice of the cross was to be continued and kept present in the church through appointed representatives and vicegerents of Christ, who for that purpose continue and partake in the priestly character of Christ and his mediatorial office between God and man. (See ORDINATION.) The other Christian denominations deny that there is in the Christian church any other real priest than Christ, since there is no one after Christ who has the power of offering sacrifices for the people. But they believe, on the other hand, in a spiritual priesthood of all Christians, which they derive from their union with Christ, the sole high priest. They therefore do not regard the clergy as an order of men specifically distinct from the laity, but only as the body of the teachers and servants of the church, who, being divinely called and properly appointed, possess certain ecclesiastical rights and undertake certain duties, which they derive partly from divine, partly from human law. (See CLERGY.) The Protestant Episcopal churches of England, Scotland, Ireland, and America have retained the word priest, to denote the second order of their hierarchy, but with very different significations, according to the different opinions entertained by the members of those churches respecting the Lord's supper.

PRIESTLEY, JOSEPH, an English theologian and natural philosopher, born in Fieldhead, in the west riding of Yorkshire, March 13, 1733, died in Northumberland, Penn., Feb. 6, 1804. He was the son of a cloth dresser, and both of his parents, and also an aunt by whom he was adopted after his mother's death, were Calvinistic dissenters. Early remarkable for his love of reading and study, he was designed by his friends for a learned profession, and was instructed in the classics in a free grammar school. He learned Hebrew in his holidays under a dissenting minister, and with little instruction made progress in the Chaldaic, Syriac, Arabic, French, Italian, and German. His mother had deeply impressed him with religious and moral sentiments, and even in boyhood his seriousness bordered upon melancholy, condering him averse to boyish sports and light reading. Though obliged by ill health to abandon his studies for a time, he entered at the age of 19 the dissenting academy at Daventry (now incorporated with New college, London) as a theological student. It was then under the care of Mr. Ashworth, successor of Dr. Doddridge. He formed the strictest habits in the methodical division of his time and labor; noted in a diary the occurrences of every day, the books which he read, and the reflections suggested; arranged at the beginning of every year his plan of study for the whole period, and at the close took an account of what he had done, compared it with what he had purposed, and struck the balance with a merchant's exactness. He had become an Arminian before leaving home, and on account of his doubts concerning orthodoxy had not been admitted a communicant of the Calvinistic church. Theological doctrines were constantly discussed at Daventry, and he usually defended the heterodox side, though, he says, the extreme of heresy in the place was Arianism. While at the academy he composed the first part of his "Institutes of Natural and Revealed Religion," published in 1772–'4. In 1755 he was invited as assistant minister to the Independent congregation in Needham Market, Suffolk, where he remained 3 years, suspected of heresy and not popular either as a preacher or teacher. He there renounced the doctrine of the atonement, and wrote his "Scripture Doctrine of Remission," published in 1761. His second engagement was at Nantwich, Cheshire, where he opened a day school, and by strict economy was able to purchase an air pump and electrical machine, with which he began his researches in natural philosophy. His reputation for ability and diligent investigation gradually extended, and in 1761 he was chosen to succeed Dr. Aikin as professor of belles-lettres in Warrington academy. He married, and composed several works, as the "Theory of Language and Universal Grammar" (1762), "Chart of Biography" (1765), "Essay on a Course of Liberal Education for Civil and Active Life" (1765), "Chart of History" (1769), "Laws and Constitution of England" (1772), "Oratory and Criticism" (1777), and "History and General Policy" (1788). During the same period he was interested in general politics, on which he delivered lectures. On a visit to London he was introduced to Dr. Price, Dr. Franklin, and others, and was advised by Franklin to attend more particularly to experimental philosophy. He undertook to write a history of electrical discoveries, for which Dr. Franklin furnished him the requisite books; the work was published, with an account of many experiments by himself, in 1767; it reached its 5th edition in 1794, though rapidly and carelessly written amid other engagements. In 1768 he was chosen pastor of a large congregation in Leeds, where he devoted much of his attention to theological subjects. About the same time he was elected to the royal society, and received the title of LL.D. from the university of Edinburgh. In 1772 appeared his "History and Present State of Discoveries relating to Vision, Light, and Colors," which proved less successful than his "History of Electricity." A brewery near his residence suggested to him the study of pneumatic chemistry, which he prosecuted with great interest, published a pamphlet on "Impregnated Water with Fixed Air" (1772), and received from the royal society the Copley medal for "Observations on the Different Kinds of Air" (1773). He discovered oxygen gas, which he named dephlogisticated air; showed that the red color of the arterial blood is due to its combination with oxygen from the atmosphere; proved the abstraction of oxygen from the atmosphere in the processes of combustion and putrefaction; and recognized the property of vegetables to restore this constituent. He adhered to the phlogistic theory after Lavoisier had overthrown it by further investigation. He discovered also nitrous gas, nitrous oxide gas, nitrous vapor, carbonic oxide gas, sulphurous oxide gas, fluoric acid gas, ammoniacal gas, and muriatic gas; and he was the principal inventor of the pneumatic trough. He received an advantageous proposal to accompany Capt. Cook on his second voyage to the South sea, which was however withdrawn in consequence of his religious principles. His name as a man of science was now honored throughout Europe, and the recommendation of Dr. Price made him favorably known to the earl of Shelburne, who engaged his services as librarian and literary companion. He accompanied the earl on a journey to the continent, and was introduced to some of the most celebrated chemists and mathematicians, whom he described as atheists, and whom he astonished by asserting his firm belief in Christianity. As an answer to similar prejudices he wrote his "Letters to a Philosophical Unbeliever" (1780), and his "State of the Evidence of Revealed Religion," with animadversions on Gibbon (1781). He continued his chemical experiments, making discoveries concerning aëriform bodies, which he reported in his "Experiments and Observations on Air" (5 vols., 1774–'80). He published in 1775 his "Examination" of Drs. Reid, Beattie, and Oswald, designed to refute the Scotch philosophy of common sense; in 1777, his "Disquisitions relating to Matter and Spirit," a defence of avowed materialism, which was more obnoxious than any other of his writings; and in the same year his "Doctrine of Necessity," of which also he became the champion. The odium occasioned by these works was perhaps the cause of the dissolution of his connection with Lord Shelburne; and he retired with a pension for life of £150. He took up his residence near Birmingham, where in 1780 he became pastor of a dissenting congregation. At the same time a subscription was raised by his friends to defray the expenses of his experments. In 1782 appeared his "History of the Corruptions of Christianity," which was afterward burned by the common hangman in the city of Dort, and a refutation of which was one of the subjects of the Hague prize essays; and in 1786 his "History of Early Opinions concerning Jesus Christ." In each of these works the divinity and preëxistence of Christ are controverted on historical grounds. During the excitement caused by the outbreak of the French revolution he was regarded as the mover and champion of antagonism to all establishments, political and religious. His attachment to freedom he had evinced by several pamphlets and by his interest in the cause of America during the war of the revolution; and he had published several volumes in maintenance of the claims of dissenters. He exasperated the populace by his ironical "Familiar Letters to the Inhabitants of Birmingham," and by answering Burke's "Reflections," and being consequently nominated a citizen of the French republic. In 1791 some of his friends celebrated the anniversary of the capture of the Bastile; and though he was not present himself, the event was the occasion of a riot in which his house was broken open, his library, apparatus, and manuscripts destroyed, and himself obliged to flee from the place with his family. His books were strewn over the high road for half a mile; the scraps of the manuscripts covered the floors several inches deep; and finally it was unsuccessfully attempted to set the house on fire. He received ample remuneration from the country and chiefly from private benevolence, and removed to Hackney to succeed Dr. Price; but noticing that his society was avoided even by his philosophical associates, and despairing of any further tranquillity in England, he resolved on emigration to America. He arrived in New York June 4, 1794, was received with distinction, took up his residence in Northumberland, Penn., where his son had an agricultural settlement, and soon established himself in his old habits, busily writing and experimenting. He was offered the professorship of chemistry in the university of Pennsylvania, but declined it. He delivered two courses of public lectures in Philadelphia in 1796 and 1797 on the "Evidences of Revelation," which were published and dedicated to John Adams, who was one of his auditors. He wrote and published in America his "Continuation of the History of the Christian Church from the Fall of the Western Empire to the Present Times" (4 vols., Northampton, 1803), which was dedicated to Jefferson, and also several minor theological works, among which were answers to Volney's and Paine's attacks on revelation. He never completely recovered from an illness in Philadelphia in 1801, but he continued to write diligently till near his death. In 1803 he asked his physician if he could prolong his life 6 months, adding that in that time he could complete all the works on which he was engaged. In his last illness he dwelt upon the happiness of his life, since he had enjoyed the friendly acquaintance of some of the best and wisest men of his age; and his death was so calm that it was not noticed by those who were sitting nearest to him. His *éloge* was read before the French institute by Cuvier. He was remarkable for philosophic serenity of character, for patience and zeal in public life, and for kindness in domestic relations. His "Doctrines of Heathen Philosophy compared with those of Revelation" appeared posthumously. His autobiography, continued by his son, was also published in America posthumously, and is contained with his correspondence in the edition of his "Theological and Miscellaneous Works" published by John Towell Rutt (25 vols., Hackney, 1817 *et seq.*).

PRIESTS OF THE MISSION, or **Lazarists**, a congregation of regular clerks, founded at Paris in 1625, by St. Vincent de Paul, for the purpose of ministering to the spiritual wants of the poor. While Vincent was residing with the count de Joigny, the father of Cardinal de Retz, he spent much of his time in preaching to the peasantry on his patron's estate, and effected so much good that the countess became desirous of founding a regular company of missionaries to engage in similar labors. In concert with her husband she obtained in 1624 from the count's brother, Jean François de Gondi, archbishop of Paris, a grant for this purpose of the *collège des bons enfants*. She endowed the projected congregation with the sum of 40,000 livres, and having persuaded Vincent to undertake the direction of it, the enterprise was put into execution the following year. The associates at first were but 2 in number, and when the deed of foundation was signed in Sept. 1626, they had only increased to 4. In May, 1627, Louis XIII. issued letters patent confirming the foundation, and in 1632 the missionaries were erected into a congregation by Pope Urban VIII. under the title of "Priests of the Congregation of the Mission." In the same year Adrien Le Bon, prior of St. Lazarus, a house of the canons regular of St. Augustine in Paris, placed them in possession of his priory, from which they have been popularly known as Lazarists. Their first establishment in Rome was made in 1642. In 1643 they were introduced into the Barbary states, in 1646 into Ireland, and in 1648 into Madagascar. The congregation was established in the United States in 1817. The priests of the mission devote themselves especially to the laboring classes, and it was stipulated in the original deed of endowment that they should "neither preach nor administer any sacrament in cities which are the seats of bishops, archbishops, or of courts of justice, except in cases of extreme necessity." They receive no compensation for their ministerial offices. Auxiliary to their personal labors for the poor are their institutions for the education and improvement of the clergy. Very soon after their foundation the direction of a number of ecclesiastical seminaries in France was committed to them, and they have ever since been actively employed in teaching candidates for the priesthood wherever they have been established. They also have houses to which priests may retire from the world for religious exercises, called "spiritual retreats." The priests of the mission take the usual monastic vows of poverty, chastity, and obedience. In 1860 the congregation had 15 houses in France, 28 in Italy, 6 in Germany, 1 in Great Britain, 1 in Spain, 17 in Turkey, Persia, and Abyssinia, 11 in the United States and 4 in other countries of America, 5 in Poland, 2 in Algeria, 1 in Cuba, and 1 on the Philippine islands; beside which, they have in China the entire ecclesiastical administration of 5 dioceses or vicariates apostolic.

PRIESTS OF THE ORATORY, or Oratorians, a religious society founded by St. Philip Neri. Going to Rome in his 19th year, in order to pursue his theological studies, Neri established there soon after a "Brotherhood of the Holy Trinity," to assist him in visiting the hospitals and prisons, and laboring for the conversion of sinners. The brotherhood assembled once a month, and the founder prescribed for them certain religious exercises. After they had been joined by several persons of high rank, they determined to build a large hospital to entertain during 3 days all poor pilgrims who came to Rome in order to pray at the tombs of the apostles, martyrs, and saints. This hospital was completed in 1558, and in the same year Pope Paul IV. presented to the association the church of St. Benedetto, now the church of the Holy Trinity. After having been ordained priest (1551), Neri associated with himself several young priests, and gradually matured the plan of the "Congregation of the Oratory." One of its first members was the celebrated Baronius. The congregation was formally established in 1564, confirmed in 1575 by Pope Gregory XIII., and again by Paul V. in 1612. During the lifetime of Philip the congregation extended through all parts of Italy, new houses being established at Florence, Naples, Lucca, Padua, and many other places. Neri remained the superior of the congregation until 1593, when he resigned, and was succeeded by Baronius. The congregation was almost always confined to Italy; but in recent times a flourishing branch has been established in England, nearly all the members of which were formerly clergymen of the church of England. They have there two establishments, at London and Birmingham, and among their members John Henry Newman and F. W. Faber are best known. At the beginning of 1860 they had 41 houses in Italy, 1 in Dalmatia, 2 in Spain, 1 in Poland, 9 in Mexico, and 1 in the island of Ceylon.—The French Oratorians, or the congregation of the Fathers of the Oratory of Jesus, were founded in 1611 by the abbé (afterward cardinal) Bérulle, and confirmed by a bull of Paul .V., May 10, 1613, under the name of "Priests of the Oratory of Jesus." Their aim was the restoration of ecclesiastical discipline among the clergy. They spread rapidly in France and elsewhere, and during the lifetime of their founder houses were established in Madrid, Rome, and Constantinople, and in Savoy and the Netherlands. The congregation soon became distinguished for the great number of eminent scholars among its members, such as Thomassin, Malebranche, Massillon, Morin, and Richard Simon. They became deeply involved in the Jansenist controversy, and at the elections of several superiors general they were divided into a Jansenist and an anti-Jansenist party. After the outbreak of the French revolution a considerable number of Oratorians joined the constitutional church. The congregation itself with all other religious associations, was dissolved. After the reëstablishment of the Bourbons, the Oratorians reorganized themselves, but in 1860 they had only one establishment, which was in Paris.

PRIMATE, a title of honor given to certain archbishops, and generally designating the chief archbishop of a country or district, who possesses a superiority of power or dignity over the other archbishops or bishops. In the Anglican church, the archbishop of York is styled primate of England, and the archbishop of Canterbury primate of all England, the archbishop of Dublin primate of Ireland, and the archbishop of Armagh primate of all Ireland.—In the Roman Catholic church, the primatial see of Ireland is Armagh, of Spain Toledo, of Portugal Braga, of Germany Saltzburg, of Hungary Gran, and of Poland Gnesen. In France 6 archbishops have received the title of primate, viz.: those of Lyons, Sens, Bourges, Bordeaux, Arles, and Vienne; but the dignity there is now merely titular. In the United States there is no primate, though the archbishop of Baltimore has an honorary precedence of all other Roman Catholic archbishops in this country.

PRIMATICCIO, Francesco, an Italian painter, born in Bologna in 1490, died in Paris in 1570. His first instructions in painting were derived from Innocenzo da Imola and Il Bagnacavallo, two Bolognese artists, and he subsequently passed 6 years at Mantua in the school of Giulio Romano, whom he assisted in the frescoes in the Palazzo del Te. Francis I. of France having commissioned the duke of Mantua to send him an artist to decorate the royal chateau at Fontainebleau, Primaticcio was selected for the purpose, and in 1531 repaired to the French court. The remainder of his life was passed in the service of Francis and his successors Henry II., Francis II., and Charles IX. His chief work in France was the series of frescoes at Fontainebleau representing scenes from ancient mythology and the Odyssey, in the execution of which he was assisted by his pupil Nicolo dell' Abati. The greater part of them were destroyed in 1738 to make way for some alterations in the chateau. Primaticcio was one of the most facile and inventive of the followers of Raphael.

PRIME. I. SAMUEL IRENÆUS, D.D., an American clergyman, born in Ballston, Saratoga co., N. Y., Nov. 4, 1812. He entered Williams college, Mass., at the age of 13, was graduated in 1829, and, after a course of study at the Princeton theological seminary, entered the ministry of the Presbyterian church. In 1840, being compelled by ill health to relinquish the active duties of his profession, he assumed the editorial charge of the "New York Observer" newspaper, one of the chief organs of his denomination, and his connection with which has continued to the present time. His contributions to this publication signed "Irenæus" have had considerable popularity, and under his management the "Observer" has become one of the leading religious periodicals in the country, beside acquiring a reputation for the conservative character of its political views. Dr. Prime is the author of "Travels in Europe and the East" (2 vols. 12mo., New York, 1855), and a work on Switzerland, the results of an extended journey in 1853, and of several works of a religious character, including "Thoughts on the Death of Little Children" and "The Power of Prayer," the latter of which, a sketch of the Fulton street (New York) prayer meeting, has been republished in several European languages. II. WILLIAM COWPER, brother of the preceding, an American author, born in Cambridge, Washington co., N. Y., Oct. 31, 1825. He was graduated at Princeton college, N. J., in 1843, and subsequently became a member of the bar in the city of New York, where he has continued until the present time, engaged in literary pursuits and the practice of his profession. Among his miscellaneous publications are "The Owl Creek Letters," consisting of papers originally contributed to the New York "Journal of Commerce;" "The Old House by the River" (12mo., 1853); and "Later Years" (1854). In 1855–'6 he travelled extensively in the East and elsewhere, and published upon his return "Boat Life in Egypt and Nubia" (12mo., 1857), and "Tent Life in the Holy Land" (12mo., 1857). He has since devoted much attention to numismatics and Egyptian antiquities, and in 1860 he edited a work entitled "Coins, Medals, and Seals" (4to.).

PRIMOGENITURE, a rule of law which confers a dignity or estate in lands on a person in virtue of his being the eldest male of those who would inherit. A preference of sons to daughters was a feature common to many of the ancient systems of law; but few or none of them recognized what in our time is meant by the custom of primogeniture. Among the Jews, the first born son as such received a double portion of his father's estate. If a Greek father died intestate leaving daughters only, his property went to his nearest kinsman. His will, if in such a case he made one, passed his estate not to his daughters, but to their future husbands. The earlier Roman law excluded daughters from the inheritance. Justinian first admitted them to share equally with their brothers. The Mohammedan law gave something to daughters, but allowed a twofold share to sons. The states of Europe which, after the decline of the Roman empire, made the later Roman law the basis of their jurisprudence, did not find in that code the doctrine of primogeniture. In France, for example, all historical evidences show that under the first two races of kings, at least, the eldest son shared equally with his brothers. Especially and certainly is this true of the succession to the crown in those reigns, where most naturally the custom of primogeniture would have been enforced if it had at all prevailed. It was not until the Capets came to the throne that the prerogative of succession to the crown was reserved exclusively to the first born. The lords promptly imitated the kings, and secured their fiefs to their eldest sons, and thus founded in France the *droit d'aînesse*. Whatever may have been in any country the immediate origin of primogeniture, the custom was no doubt everywhere the peculiar policy of the feudal system. To make certain and efficient the render of military service, which was at once the cause and consideration of the grant of feuds (or fees), it was expedient to render these indivisible. The fittest successor to the original holder, as being the one first capable of doing military duty, was the eldest son; and to him accordingly the feudal law quite invariably transmitted the father's lands. —It is possible, perhaps probable, that in England, before the Norman conquest, the custom still prevalent in Kent, and known as gavelkind, extended over the whole island. In virtue of this custom, the lands of one who died intestate, leaving sons and daughters, descend in equal divisions to the sons, exclusive of the daughters; but if he leave no sons, then the daughters share alike. But whatever be the truth in respect to this matter, certainly the conquest introduced the policy and rules of the continental feudal system, and thus prepared the way for the general adoption of the custom of primogeniture; so that eldest sons acquired the right of succession, primarily, to the lands held in fee, and consequently to the titles of dignity which were appurtenant to them. The canon of the common law touching descents which pertains to this subject is, that if a man dies seized of real estate of which he had the absolute ownership, without having made any disposition of it by his last will, the whole descends to his heir at law; and this heir at law is that one of his representatives who is the eldest male among those who are in the same degree of kindred. On this rule rests the English custom, and, as Gibbon calls it, the "insolent prerogative" of primogeniture. Large landed estates, however, are perpetuated in families in England far less by this custom of primogeniture (which does not interfere with the owner's legal capacity of testamentary disposal) than by the system of settlements and entails, which rests on principles quite distinct from the former. The English law once allowed land to be entailed interminably, but this power has been gradually reduced, until now the longest settlement can extend only 21 years beyond lives in being when it is made, and the preference of the eldest son, though universal, is in this case altogether voluntary, as in that of a will. Yet the entail very rarely expires with the original limitation, as the first heir on coming of age may join with the existing possessor in resettling the estate and so prolonging the entail. In case of personal property, the right of primogeniture does not exist. In France primogeniture was abolished in 1789, and since that period the tendency of legislation in all countries except the British islands has been to its abolition. In Portugal, where the custom of primogeniture most extensively prevailed, the younger sons of the great families, though too proud to work, were not ashamed to beg, and not rarely lived on alms. In France they crowded into the church and the army, or led a life of complete and often destitute idleness.

PRIMROSE (*primula vulgaris*, Linn.), an early flowering perennial plant, native of Europe, with many single, pale yellow blossoms, which spring from a common stalk concealed in the bosom of the foliage, thus rendering them apparently stemless; its leaves are all radical, erect, oblong-ovate, unequally crenate, smooth above, but veiny, wrinkled, and somewhat rough beneath; flowers with keeled, tubular calyces, divided at top into 5 sharply pointed teeth; the corolla monopetalous, salver-shaped, with 5 entire, spreading segments; stamens 5, with very short filaments and erect anthers; pistil furnished with a long straight style; fruit a capsule filled with numerous brown seeds. The plant delights in a moist, cool, clayey soil, and under cultivation is subject to many variations, there being white, purple, lilac, and even double-flowered permanent varieties known to florists. Even the polyanthus has been known to spring from it, when some peculiarity of soil has affected the plant; and though classed by most botanists as a distinct species under the name of *P. elatior*, it is considered by many as no more than a permanent variety, with brown-colored flowers elevated on a taller peduncle and liable to infinite, richly marked tints, spots, and pencillings of the corolla. (See POLYANTHUS.) A very popular species, much cultivated as a house plant, is the Chinese primrose (*P. Sinensis*, Lindley), with downy, soft, large-toothed leaves on long footstalks, and numerous pale lilac blossoms borne in a spreading umbel upon a common scape. There are varieties with white flowers, others with fringed or fimbriated petals of great beauty, and others with double flowers, all desirable on account of their continuing in bloom the entire year, but of special interest in the winter months. They are readily raised from seeds and from cuttings, preferring a rich, sandy soil.—In the United States the primrose is represented by the bird's-eye (*P. farinosa*, Linn.), found on the shores northern lakes, having elliptical or lanceolate leaves, the lower surfaces entire involucre covered with a white powder; the flowers 3 to 20 in numb ing a yellow eye in the centre of the pa corolla; and by a pretty species 2 to high (*P. Mistassinica*, Mx.), with thin, veiny leaves, flowers 1 to 8 in the corollas broadly and deeply ob flesh-colored, found in the northern of the state of New York and of Verm on the shores of the upper lakes.—The of primrose is also applied to the gen *thera*, comprising rank, coarse-leaved common to Europe and seen in gard the finest species of which are natives western prairies, with large conspicuous soms, either lemon-colored or white. the blossoms opening at sunset, these been termed evening primroses.

PRINCE (Lat. *princeps*), a title apper to a sovereign, to the male offspring of or to persons of eminent rank who are w the attributes of sovereignty. The word *ceps* was employed by the Romans to a senator of rank who held the office of of the city, and was adopted by August his successors in the imperial chair as a dignity. In England the title strictly only to persons of the blood royal, who it by right of birth, and without a formal ment, as in the creation of dukes or ot ders of nobility. The younger sons of ereign retain it until another title is con upon them, but the daughters remain cesses. A special exception is made in case of the eldest son, who is created by prince of Wales. In France, under the *gime*, the title was borne principally by of distinction connected with the blood as the members of the houses of Orleans Bourbon-Condé. Napoleon I. conferred it several of his marshals and ministers. Pre to the present century Germany comprehe a number of petty states called principali and governed by hereditary princes, many whom at present have no territorial sovere ty. In Russia, where it was formerly born the sovereigns, and elsewhere in Europe, title is one of the highest recognized.

PRINCE, THOMAS, an American clergym and historian, born in Sandwich, Mass. 15, 1687, died Oct. 22, 1758. He was educ at Harvard college, and in 1711, after visi Barbados and Madeira, settled as pastor of a church at Combs, in Suffolk, England. he remained until about 1717, when he turned to Massachusetts accompanied by eral of his congregation, and shortly afterw became colleague of the Rev. Joseph Sew at the Old South church in Boston, where remained until his death. In 1727 appea the first volume of his "Annals of New land," materials for which he had coll with great care while in England. It was proved by the legislature, but owing to the indifference of the public was never completed. He also published a number of sermons, and devoted the last year of his life to a revision of the New England version of the Psalms.

PRINCE EDWARD, a S. co. of Va., bordered N. by the Appomattox and S. by the Nottoway river, and drained by several small streams; area, about 350 sq. m.; pop. in 1860, 11,844, of whom 7,341 were slaves. It has a diversified surface and a generally fertile soil, and contains mines of coal and copper. The productions in 1850 were 314,359 bushels of Indian corn, 75,702 of wheat, 87,229 of oats, 2,571,850 lbs. of tobacco, and 10,189 of wool. There were 9 grist mills, 6 tobacco factories, 3 tanneries, 1 iron foundery, 1 newspaper office, 24 churches, and 877 pupils attending public schools. Toward the N. it is intersected by the south side (Petersburg and Lynchburg) railroad, and across the S. E. by the Richmond and Danville railroad. Capital, Prince Edward Court House.

PRINCE EDWARD ISLAND, an island and colony of British America, situated on the S. side of the gulf of St. Lawrence, between lat. 45° 58' and 47° 7' N., and long. 62° and 64° 27' W.; length about 140 m., breadth from 5 to 40 m.; area, 2,134 sq. m.; pop. in 1855, 71,502. It is divided into Prince's, King's, and Queen's counties, the capitals of which are respectively Princetown, Georgetown, and Charlottetown. It is separated from Nova Scotia and New Brunswick by Northumberland strait, which varies in width from 9 to 30 m. The shores are indented by numerous bays, some of which extend so far inland that the island is divided into 3 peninsulas connected by narrow isthmuses, one of which is only about 1 m. broad. The coasts are bold and lined with red cliffs, varying from 20 to 100 feet in height. The surface is well diversified, and watered by numerous springs and rivers. The soil is fertile, and consists for the most part of a thin layer of decayed vegetable matter over a light loam about a foot deep, below which is a stiff clay generally resting upon sandstone. No valuable minerals have been discovered. The climate is very healthy, and much milder than that of the adjoining continent, and is generally free from fogs such as are prevalent on the shores of Cape Breton and Nova Scotia. The island was formerly covered by extensive forests, but they have been nearly all removed, and there is now only sufficient timber for industrial purposes. All kinds of grain, fruit, and vegetables common to temperate regions succeed remarkably well, and bear abundant crops. The breeds of domestic animals have lately been much improved by stock imported from England, and wild animals have become scarce. Seals are found in the bays and on the coasts, and vast numbers of them sometimes arrive on the ice from the Polar sea. Prince Edward Island is one of the best fishing stations on the gulf of St. Lawrence, and the harbors on the N. coast are much frequented. The fishery is principally in the hands of fishermen from the United States, who during the summer months employ from 200 to 300 vessels. The manufactures are of very little importance; and the trade consists of the exchange of agricultural produce, timber, and some fish, for American and British manufactures. During the year 1858-'9 the total value of the exports was $362,741. The population is composed of mixed races, about $\frac{2}{3}$ of the whole being natives of the island. The civil establishment consists of a lieutenant-governor and a chief justice, with the usual assistants. In 1852 the revenue was £20,856 and the expenditure £14,857. Citizens of the United States can hold land in the colony to the extent of 200 acres. The island is in telegraphic communication with the continent of America.

PRINCE GEORGE. I. A S. W. co. of Md., bordered E. by the Patuxent river, and W. by the Potomac and the district of Columbia, and drained by the west branch of the Patuxent, and Piscataway and Anacosta creeks; area, about 600 sq. m.; pop. in 1860, 23,327, of whom 12,479 were slaves. Its surface is somewhat hilly, and contains great quantities of iron ore; the soil is generally very fertile. The productions in 1850 were 1,500,045 bushels of Indian corn, 231,687 of wheat, 67,226 of oats, 47,458 of potatoes, 5,587 tons of hay, 13,409 lbs. of wool, 100,947 of butter, and 8,380,851 of tobacco (the largest amount of tobacco yielded by any county in the Union). There were 4 grist mills, 2 cotton factories, 1 woollen factory, 1 iron furnace, 1 newspaper office, 31 churches, and 240 pupils attending public schools. It is intersected by the Baltimore and Washington railroad. Capital, Upper Marlborough. II. A S. E. co. of Va., bordered N. by James river and N. W. by the Appomattox, and drained by the sources of the Blackwater; area, about 350 sq. m.; pop. in 1860, 8,410, of whom 4,996 were slaves. Its surface is hilly and the soil moderately fertile. The productions in 1850 were 261,510 bushels of Indian corn, 81,042 of wheat, 23,600 of oats, and 16,550 lbs. of tobacco. There were 14 churches, and 198 pupils attending public schools. Value of real estate in 1856, $1,962,626, showing an increase of 45 per cent. since 1850. The N. W. portion is traversed by an extension of the Petersburg and Lynchburg railroad. Capital, Prince George Court House.

PRINCE WILLIAM, a N. E. co. of Va., bordered E. by the Potomac and N. E. by the Occoquan river, and drained by Cedar Run, Broad Run, and Quantico creeks; area, about 325 sq. m.; pop. in 1860, 8,565, of whom 2,356 were slaves. It has a hilly surface and sandy soil. The productions in 1850 were 161,248 bushels of Indian corn, 57,726 of wheat, 57,717 of oats, 2,309 tons of hay, 25,978 lbs. of wool, and 79,079 of butter. There were 19 grist mills, 8 saw mills, a woollen and a cotton factory, 16 churches, and 916 pupils attending public schools. Value of real estate in 1856, $2,585,-698, showing an increase of 52 per cent. since 1850. It is intersected by the Orange and Alexandria railroad, a branch of which, the Manassas Gap railroad, traverses the northern portion. Capital, Brentsville.

PRINCESS ANNE, a co. forming the S. E. extremity of Va., bordered N. by Chesapeake bay, E. by the Atlantic, and S. by North Carolina; area, about 400 sq. m.; pop. in 1860, 7,714, of whom 3,186 were slaves. It has a level surface and sandy soil, and contains large forests of pine and cypress, affording an important lumber trade. The productions in 1850 were 347,141 bushels of Indian corn, 60,024 of oats, 2,529 of wheat, 1,593 tons of hay, and 12,115 lbs. of wool. There were 4 grist mills, 3 saw mills, 17 churches, and 819 pupils attending public schools. Value of real estate in 1856, $1,499,146, showing an increase of 22 per cent. since 1850. Capital, Princess Anne Court House.

PRINCETON, a township and village of Mercer co., N. J., within a mile of the New Jersey railroad and the Delaware and Raritan canal, 40 m. N. E. from Philadelphia, and 11 m. N. E. from Trenton; pop. of the township in 1860, 3,772; of the village, 3,160. The village is neatly built and pleasantly situated, and contains a theological seminary of the Presbyterian church, founded in 1812, a bank, a newspaper office, and several churches. It is the seat of the college of New Jersey, founded at Elizabethtown in 1746 by the Presbyterian synod of New York, then separated from the synod of Philadelphia, under a charter obtained from the colonial government. Jonathan Dickinson was its first president, but died in the following year. In 1748 a new charter was obtained through Governor Belcher, and the Rev. Aaron Burr was chosen president. The college was removed to Princeton in 1757, in which year President Burr died, and in 1757 Jonathan Edwards, his father-in-law, assumed the office, but lived scarcely long enough thereafter to even enter upon his duties. The next incumbent, the Rev. Samuel Davies, accepted the presidency in 1759 after a second appointment, having declined the first, but died in 1761, less than two years after his installation. The Rev. John Maclean, the present incumbent, inaugurated in 1854, is the 10th president of the college. Nassau hall, erected in 1756 for the use of the college, was at that time considered the largest and one of the finest buildings in the colonies. In 1777 it was occupied by British troops, in 1802 nearly destroyed by fire, and on March 9, 1855, entirely consumed. In 1860 the college had 19 instructors, 314 students, 3,796 alumni, and a library of 24,000 volumes.

PRINCETON, Battle of. After the defeat and capture of the Hessians at Trenton, Dec. 26, 1776, Cornwallis, who was about embarking for England, resumed his command of the British in the Jerseys, and, having concentrated his forces at Princeton, advanced (Jan. 2,
with nearly the whole force to Trent
occupied by Washington and the Amer
army. It was nightfall before the British
established themselves on the W. bank
Assunpink, a small stream fordable in
places, and crossed by a bridge command
the revolutionary troops, and Cornwall
cided to postpone the decisive attack until
day. Washington, finding himself oppo
an army superior in discipline and numb
his own brave but inexperienced troop
cut off from retreat by the Delaware,
with ice, and impassable within the time
able for escape, projected a diversion to
Princeton, where, by attacking and def
the remaining troops, he could seize upo
supplies and munitions stored there and
proceed to Brunswick. Gen. Leslie wit
rear guard of the British army was at Ma
head, about half way between the two p
and 3 regiments of infantry and 3 tr
of dragoons were still at Princeton. A
of Leslie's position, Washington determi
make a detour by the Quaker road, whi
scribed a circuit until within 2 m. of Prin
where it joined the main road; but it was
in good condition, and the march was imp
so that it was sunrise before he reach
bridge at Stony Brook, about 3 m. from Pr
ton. Here he took a shorter and more conce
road, and ordered Gen. Mercer to proce
the brook and take possession of a brid
the main road. Thus far the enemy were
ware of his movements. At the Assunp
detachment was left to dig trenches in
that the noise might be heard in the B
camp, to keep and relieve guard, and to
the camp fires. They were ordered to h
after the main army at daybreak. The bag
had been quietly removed to Burlington.
British remaining at Princeton had comme
their movement toward Trenton, and
Mawhood having passed the bridge on the
road over Stony Brook, while marching thro
a wood discovered Mercer's advance, and
posing them a portion of the defeated Amer
army, put back to intercept their flight. A
emerged from the wood and recrossed the br
he came upon Mercer's brigade. At once
made for a piece of rising ground to obtain
advantage of its position. It was gained
the Americans, who opened a sharp fire on
enemy, which they vigorously returned.
their first fire the horse of Mercer was ki
and a colonel mortally wounded. The Brit
availing themselves of the resulting confu
charged with the bayonet, a weapon of wh
the Americans were destitute, and after a s
struggle, during which Gen. Mercer rece
several desperate wounds which in a few d
proved fatal, they gained the position and dr
the Americans before them. After a sh
pursuit the British were brought to a st
by a detachment of Pennsylvania troops de
patched by Washington, on hearing the fir

he assistance of Mercer. Mawhood halted, opening his artillery on the reinforcement pped their advance. At this critical mo- nt Washington appeared on the field. De- ling at once the desperate state of affairs, he loped forward among his broken troops, o, inspired by his gallantry, rallied and re- ned the battle, while a regiment of Virgin- s came up, and an American battery which just arrived opened its fire upon the enemy. e action was fiercely contested; Col. Maw- od fought with the most desperate bravery, d eventually forcing his way by the bayonet the main road, retreated toward Trenton. ring this struggle Washington distinguished nself by his personal daring, rushing into the ckest of the fight, and animating his men the example of his own courage. The 55th tish regiment had in the mean time been ountered by the advance guard under Gen. Clair, had given way, and was in full re- t toward Brunswick. The remaining regi- nt, not having been able to get up in time participate in the engagement, divided, a tion retreating toward Brunswick, and the taking refuge in Nassau hall, belonging to college of New Jersey, but for some time upied by the British as barracks. These rendered after receiving a few shots from an erican battery. In this action, so gallantly ducted by the wearied, poorly fed, and rly clad Americans, their loss was not more n 30 men, beside Gen. Mercer, Cols. Haslet d Potter, Major Morris, and 3 captains. The tish left about 100 dead on the field, and rly 300, including 14 officers, yielded them- es prisoners. Washington now moved on Morristown, destroying the bridges on his rch, and confined himself for some time erward to a system of persistent annoyance, ich had the result of driving the enemy out nearly the whole of New Jersey.

PRINCIPATO CITRA, a central province Naples, bounded N. W. and N. by the prov- es of Terra di Lavoro and Principato Ultra, and S. E. by Basilicata, and S. and W. by e Mediterranean; area, 2,271 sq. m.; pop. in 56, 589,979. Capital, Salerno. The surface much broken by offsets from the Apennines, d there are considerable tracts of level ground ng the shore of the bay of Salerno. The st line is irregular, and nearly half of it con- ts of a bold curve which forms the bay of erno. A great part of the province is watered the Sele and its affluents. The principal nerals are copper, marble, and gypsum. The chovy and tunny fishery is very productive.

PRINCIPATO ULTRA, a province of Naples, unded N. by the province of Molise, N. E. d E. by Capitanata, S. E. by Basilicata, S. by incipato Citra, and W. by Terra di Lavoro; ea, 1,409 sq. m.; pop. in 1856, 375,919. Capi- l, Avellino. The former papal territory of Ben- vento is entirely surrounded by this province. he chief rivers are the Calore and Carapella. he province is almost entirely covered with the Apennines. The soil, especially in the valleys, is fertile and well cultivated.

PRINGLE, Thomas, a Scottish poet and journalist, born at Blaiklaw, Teviotdale, in 1789, died in 1834. After passing through the university of Edinburgh, he obtained the position of clerk to the commissioners on the public records of Scotland, which he held until 1817, when he commenced the "Edinburgh Monthly Magazine," which was the germ of "Blackwood's Magazine." At the same time he was editor of the "Edinburgh Star" newspaper, and joint editor of "Constable's Magazine." He soon quarrelled with Blackwood, and, his other publications being unprofitable, went out to the Cape of Good Hope in 1820, and became government librarian at Capetown. Here he also established a private academy, founded the "South African Journal," and edited at the same time the "South African Commercial Advertiser," both of which periodicals were discontinued in consequence of the censorship exercised over them by the colonial governor. Pringle returned to Great Britain in 1826, and became secretary to the anti-slavery society, which situation he held until the abolition of slavery in the colonies, when the society was dissolved. During this period he published his "Narrative of a Residence in South Africa," upon which and upon his poems his reputation chiefly rests. A collection of his poetical works has been published, with a sketch of his life by Leitch Ritchie.

PRINTING (Lat. *imprimo*, to stamp or imprint, from *in*, upon, and *premo*, to press), the taking impressions from types or engraved plates, for the purpose of multiplying at a cheap rate reversed copies of the designs they present; including also in a general sense the preliminary processes of composing and preparing types for impression or for casting plates. In its simplest forms the art has been practised by different nations from remote antiquity. The bricks from the ruins of Egypt and of Assyria are impressed with characters stamped in the clay. Seals and signets were used by the Israelites, and in later periods the Romans used stamps for producing inscriptions, as the name of the maker or vender, upon various articles of merchandise, and brands for marking cattle with the letters of the owner's name. Some of the Roman inscriptions still in existence appear like rude printing. It has been supposed that a passage in Cicero *De Natura Deorum* giving directions respecting types made of metal, and called by him *formæ literarum* (the very name afterward applied to types by their inventors), may have suggested the idea of them. And it is not a little remarkable, considering the immense importance of the art of printing, and the labor and expense incurred by the ancients in copying books by pen, that they should have approached so near the invention of movable types without these being finally brought into use until the 15th century. Among eastern nations, as the Chi-

nese, Japanese, and Tartars, the printing of books from engraved blocks had indeed been practised from the most remote periods; a process which is not yet abandoned by the races named for movable type printing. Their method is to paste the page, prepared by the pen on tracing paper, face down upon a block of hard wood. The engraver then cuts away the portions of the wood and paper not covered with the characters, leaving these in relief. The printer, with two fine soft brushes in the right hand, blackens the whole surface of the block with the ink in one, and laying on the paper smooths it gently down with the other, which is dry, and thus obtains an impression from the raised parts alone. Each impression consists of two pages, divided by a line down the middle; on this line they are folded back to back and fastened together, so as to include the single edges in the binding and leave the folded edge in front. As noticed in the article ENGRAVING, this block printing was practised in Germany for producing playing cards and illustrations for manuscript works early in the 15th century, before movable types were invented. In their use it is not unreasonable to suppose that the idea was suggested of dividing them into parts and employing these in such combinations as might be convenient; and that the division might thus be extended to single types. The time and place of the invention of these are not known with certainty. The city of Haarlem in Holland claims that Laurens Janszoon Coster there invented the art of printing in 1423, making use of movable types of wood and afterward of lead and tin; but no printed works of his can be identified. The claims of Johannes Gutenberg to this invention are more generally recognized. He without question was occupied in various experimental researches of a secret nature in Strasbourg, and possessed in 1438 printing materials, a press, and as it appears movable types. No book, however, was brought out by their use until after Gutenberg had returned (which was about 1450) to his native city of Mentz. Here he associated himself with a wealthy citizen, Johann Faust, who, on learning the secrets of the art, entered into partnership with Gutenberg, and agreed to furnish funds for developing the process. They employed to assist them Peter Schöffer, a scribe whose previous occupation had been the copying of books, and who appears to have been a man of taste and genius, and well fitted to bring a new process of this sort favorably before the public. He has the credit of substituting metallic types cast in plaster moulds in the place of those which Gutenberg had previously made by carving pieces of wood and metal, and of still further perfecting the art by the invention of punches in hard metal, by the use of which sharpness of outline could be given to the matrices in which the types were cast, and perfect uniformity be retained in the type by continuing to use the same punches for pro
as many matrices as might be required.
inventors succeeded in printing a consid
number of books, the first of which kn
have been printed with movable types
editions of Donatus. The first work
date (1455) was the *Litteræ Indulgentiæ*
V. Pont. Max., which was complete in a
page. In the year 1462, by reason of th
ture of the city of Mentz by Count A
of Nassau, the printing operations carr
there were checked, and the printers w
persed into other states. The fame of the
had preceded them, and new enterpris
rapidly undertaken in other cities. P
presses were in operation at Subiaco ne
in 1465, and the types employed were m
those now called Roman than like the
forms of the Germans, which with the
ters imitating handwriting had up to this
alone been used. In 1469 printing wa
duced into Milan and Venice; and the p
tions of the presses of John de Spira and C
topher Valdarfar of the latter city a
great fame for their perfection and beau
devices with which these early publ
were adorned were often artistic pro
of themselves giving an interest and v
the works. As copies of the early e
became scarce, they were more and more p
and in some instances have been sold fo
ordinary sums. The highest price ever
for any printed work was for the only p
copy known to exist of Valdarfar's 1st e
of Boccaccio's *Decamerone* of 1471. It
sold at auction in London, June, 1811, and
off by the marquis of Blandford for £
Lord Spencer competing for the prize
£2,250. Printing was introduced into
in 1470, and into London in 1474. (See
TON, WILLIAM.) Before the year 150
stated, printing presses had been set up
places in Europe, and a multitude of e
of the classical writers in their appro
Greek and Latin characters were given
world. A Greek grammar wholly in G
types was printed in Milan in 1476, and
first work wholly in Roman type was Ci
Epistolæ Familiares, printed at Rome in 1
A Hebrew Bible was printed at Soncino i
duchy of Milan in 1488. Italic type wa
vented about the year 1500 by Aldus Ma
of Venice. In the United States the first p
ing press was introduced at Cambridge, M
in 1639. (See CAMBRIDGE, vol. iv. p. 29
the apparatus employed by the earliest pri
the devices on the title pages of the wor
Badius Ascensius of Lyons (1495–153
to convey some idea. The presses were si
contrivances capable of printing only 4 p
at a time, and that at two pulls; but su
they were, they continued in use with l
improvement into the 17th century. The
at first employed was apparently brown un
well ground and thin. The earliest cop
the *Speculum* and *Biblia Pauperum* were pr

with it; and the effect is said to have been
ter than that of black ink in its harmo-
with the colors of the adornments. The
k and red inks were of excellent character,
surpassed by those now in use. The black
s of a deep rich color, and so continues in
old books till the present time, and the
er near it is not in the slightest degree tar-
hed by it. It was applied to the types by
ls of skin stuffed with wool, a method not
tirely out of use in the 19th century. The
s were ground upon a stone slab with a
uller, and from this slab were taken up by
balls, which were dabbed down upon them
the purpose. Cases for the type were simi-
to those now used. The typography in
st respects was rudely executed, and some-
at obscure from the words running into one
other, from defective punctuation, and nu-
rous abbreviations. Blank spaces were left
initial letters, which were afterward filled
by those whose employment had been to
uminate the old manuscripts, a style of work
ich could not be imitated by types. Nu-
rous other ornaments in brilliant colors were
oduced by the illuminators, and the margins
the pages were often covered with figures
saints, birds, flowers, monsters, &c., which
d not necessarily any relation to the subjects
ated in the text. The types were of uniform
aracter throughout, usually Gothic letters.
e date and name of the printer were com-
only omitted, but sometimes appeared at the
d of the book. Editions were small, 200 or
0 being considered a large impression. The
anufacture of type, properly a distinct branch
om printing, was not so regarded at first,
d the printers commonly prepared their own
pe. Still the types used in different countries
metimes betray a common origin; for ex-
ple, those used by Caxton at one time in
gland were evidently of the same character
ith the types of John Brito of Bruges and of
hn Valdeuer of Utrecht. Many were fur-
shed to printers by Ulrich Zell, the father of
e Cologne press, and by Wynkin de Worde,
axton's successor. Type founding was ex-
ressly declared to be a distinct art from that
f the printer by a decree of the star chamber in
637, and 4 founders were appointed to supply
ll the printers in Great Britain with type. At
his time the mechanical execution of printed
orks had greatly deteriorated. The artistic
esigns and ornaments of the old illuminators
ad gone out of use, and the typography which
ucceeded was of very inferior character. Such
ontinued to be the case during the 17th cen-
ury. One of the first who devoted himself to
ts improvement was John Baskerville, a japan-
er of Birmingham. About the year 1750 he
ngaged in cutting punches for type, and pro-
duced those of such excellent proportions, that
ubsequent improvements have done little more
than to increase the delicacy of the lines, and
add to the variety of the forms. After his death
in 1775 his types and punches were purchased
for the splendid edition of Voltaire's works published by Beaumarchais. The art continued to be sustained in the same perfection by Bulmer, whose Shakespeare and Milton are among the most splendid specimens of typography ever executed.—During the present century a great variety of ornamental type has been introduced, the styles differing from each other in the shapes of the letters, in the heaviness or lightness of the lines, and in the shading. Great ingenuity has been exercised in multiplying these varieties in so limited a field. The largest size of type for books is called great primer, and is seen in the largest old Bibles; it is now seldom used. English, which is the next lower size, is seen in church Bibles, in folios, and some quartos. Pica, small pica, long primer, and bourgeois are the sizes most in use. The last named is the type employed in this cyclopædia. The succeeding varieties are brevier, minion, nonpareil, agate or ruby, pearl, diamond, and brilliant, the last being very rare, and the smallest type used in books. In the following list the different sizes are exhibited, each with its own name:

Great Primer, English, Pica,
Small Pica, Long Primer, Bourgeois,
Brevier, Minion, Nonpareil, Agate, Pearl, Diamond, Brilliant.

For handbills or posters special types are employed of extra large sizes. A complete assortment of one size is called a font or fount, and the "sorts" that make up an ordinary font of Roman type are as follows: 3 complete alphabets in capitals, small capitals, and small or "lower case" letters, making 78 characters; the double letters ff, fi, fl, ffi, ffl (each cast in a single piece on account of the kern or bend of the *f* not permitting it to stand separately against another f, an i, or an l), 5; the diphthongs Æ, Œ, æ, œ, *æ*, *œ*, 6; figures, 10; marks of punctuation, 6; the apostrophe, hyphen, parenthesis, and bracket, 4; 4 sizes of dashes, and braces in 5 pieces, 9; the characters &, *&*, §, £, ☞, 5; and the references *, †, ‡, §, ‖, ¶, 6; total characters, 129. Besides these, there are required for filling the blanks between words, at the ends of lines, &c., 4 sizes of spaces and 4 of quadrats (the former and the smallest of the latter being subdivisions of the em [m] or square of the size of the type, one equal to it, and the other two multiples of it), making altogether 137 sorts. To every complete font there should also be a suite of accented and long and short vowels, with the sedilla c (ç), Spanish n (ñ), &c., which are only furnished by the founders when separately ordered, making 40 to 100 additional sorts. There are many other characters only required for special occasions, as astronomical and mathematical signs. An ordinary font of Italics comprises 60 characters, viz.: 2 alphabets in capitals and small letters, capital and small diphthongs, colon, semicolon, interrogation and exclamation points; to which are to be added accents, &c. Italic small capitals are also sometimes made. The proportions of the principal pieces in a Roman font of 800 lbs. of pica (comprising altogether about 150,000 pieces) are as follows: Capitals, from 300 to 600 of each, excepting Q and X, 180 each, and Z, 80. Small capitals range one half as many of each letter as the capitals.

a	8,500	f	2,517	p	1,750	y	2,000
e	12,000	g	1,700	q	500	z	200
i	8,000	h	6,400	r	6,200	,	4,500
o	8,000	j	400	s	8,000	;	800
u	8,400	k	800	t	9,000	:	600
b	1,600	l	4,000	v	1,200	.	2,000
c	8,000	m	8,000	w	2,000		
d	4,400	n	8,000	x	400		
Thick spaces			18,000	Thin spaces			8,000
Middle spaces			12,000	Hair spaces			8,000

To place all these pieces within convenient reach of the type setter or compositor, they are distributed in the "boxes" or cells of two open cases, which are arranged sloping forward, one behind and above the other, and forming with it an obtuse angle, on a frame the top of which they cover at a convenient height for the workman, who stands in front. In the upper case, with boxes all of one size, and like the lower case in two equal divisions, are the capitals, the large ones on the left and the small ones on the right (an arrangement which is sometimes advantageously reversed), with references, braces, dashes, &c., in the top rows. The lower case contains boxes of a variety of sizes severally adapted to the quantities of type required of each letter, the central boxes most convenient to the printer's hand being the largest and containing the letters most used. The spaces, quadrats, points, and figures also have boxes in this case. The Italics are in other cases, sometimes set as drawers in the lower part of the frame. An improved form of case has been patented by Mr. Thomas N. Rooker, of New York, designed to lessen the movements of the hand of the compositor by bringing the boxes into a more limited space. A single case is employed instead of two, and the small boxes for the capitals are placed immediately adjoining those of the corresponding small letters. Another form patented by him occupies little more than half the space of the ordinary case, saving the compositor long reaches for the various sorts, and greatly increasing the amount of work he can do. The boxes are made with movable bottoms, readily raised and lowered by a screw; thus, though small, they can be made to hold type enough for a week's work, and are in effect always full until exhausted. The case for music type is similar in form to the ordinary case. The difference consists simply in the subdivision of the larger boxes, required by the greater number of music signs. The various fonts of music type, named from the size of the letter, are minion, minionette, nonpareil, agate, pearl, diamond, and excelsior. These differ slightly in the number of characters in a font, but usually contain over 200 separate signs. The lower case is occupied with the white and black notes, the lines (varying in size from an en to 4 ems), the angles ings, rests, bars, &c.; and the upper tains the characters less frequently portion of the upper case is also occu miniature notes, groupings, &c., corre to the large characters.—In setting compositor, having the copy or ma laid before him, on the upper case, an ing in his left hand the composing little iron tray capable of holding 10 lines according to the size of the ty adjusted by a slide to the exact le the line), sets the first type in the l corner of the stick against a flat thin brass or steel, called the composing or rule. He looks only to see that the typ from the right box, and seizes it i a way as to bring the nick or notch, w made on the side of every type corres to the bottom of the letter, from hi places it in the stick, the reverse of rangement of the letter when printed. succeeding letters rapidly follow, and end of each word he sets a space. On ing the end of the line he rearran spaces, so as to make it exactly full. cure a uniform separation of the wor process is called justification, and to curately and rapidly without repeated an important qualification of a good c tor. The line being finished, the co rule is taken out and slipped in front, a new line is commenced. The lines ar brought close together, and the prin designated solid. If it is desired to hav open, a slip of type metal, just the len the line and the height of the spaces a lead, is introduced between each, and fo open printing thicker leads or two or m them are used. The printing is then des leaded or thick-leaded. When the com stick is nearly filled, the rule is bro front of the last line, and the whole is off upon a larger tray called a galley. In this some skill is required to prevent the falling apart, or, as it is called, being t into pi. On the galleys the types are ma into pages. At the bottom of the first pa set a type indicating by the figure 1 or le the first sheet or "signature," and upon th page for a quarto, or 17th for an octavo, mencing another sheet, is set the figure letter B, and so on; thus designating, for venience in gathering, folding, and bi the order of the sheets; this figure or let ways appearing on the outside of the when it is folded in pages. The pages as are removed from the galleys, secured twine bound around the types, are imp *i. e.*, set in the order for printing, upon a ble or iron slab called the imposing sto pages together for a folio, 8 for a quar for an octavo, 24 for a duodecimo, &c. (be the introduction of the steam press, *half* the numbers, as indicated by the designatio The impressions of these pages are to be take

ong iron frame called a *chase* (Fr. *châsse*,
, or *châsse*, a frame), with cross bars di-
g it into quarters, is then placed down so
enclose the pages, which are secured in
proper positions by what is termed furni-
consisting of strips of wood or metal
r than the types. One tapering strip is
d along the outer side and one along the
m of each quarter, called side and foot
, and by small blocks called quoins (Fr.
a wedge) driven with a mallet and "shoot-
tick" (a tapering piece of very hard wood
ow) between these and the chase the pages
firmly held in their place. This is called
ing, and the whole is a "form." For news-
rs and other publications on large single
s the forms are used in pairs, one for each
of the sheet, that having the first page
g called the outer, and the other the inner;
in nearly all book work each form is now
e complete in itself, called a half sheet impo-
n, and the sheets of paper, when the whole
ion has been printed on one side, are turned
for end and printed on the other from the
e type, and afterward cut in two. The ar-
gement of the pages for a quarto may be
by spreading out one of the double news-
ers of the day of 8 pages. One side, it will
bserved, comprises the 1st, 8th, 4th, and
pages, belonging to the outer form, and the
er side the remaining pages. As the num-
of pages to a form increases in octavos,
decimos, &c. (sometimes, for miniature vol-
s, as many as 128), the arrangement be-
es more complicated. A first proof is
n from the types commonly before they
made into pages; for which purpose they
temporarily secured on the galley, and being
ed, a sheet of paper is laid on and pressed
n by a hand roller. This proof is examined
the proof reader, and the errors being
ked after the plan indicated in the article
ECTION OF THE PRESS, the compositor picks
the types that are to be removed and in-
s others as required. After being made up
o pages other proofs are taken to be read
the author or other readers, and the correc-
ns are introduced by unlocking, *i. e.*, loos-
g the quoins, so that some types may be
en out and others set in. It is obvious that
work of the compositor may be greatly in-
ased by inattention on the part of the cor-
ctor to substituting the same quantity of mat-
r for that removed. To take out or add a
rtion of a line may involve the respacing of
ny lines, and a more considerable change in
e quantity may require a new adjustment of
l the succeeding pages that are made up. The
s on which compositors in American print-
offices are paid for their work is the esti-
ed number of "ems" or squares (compris-
about 2 letters each) he has set, the price
ing so much per thousand. In this estimate,
book work, so many lines are allowed for a
e as the types would make in solid printing,
including the heading over the top and the line of quadrats at the bottom, and these are multiplied by the number of ems in a line; thus, the number of pages being given, the whole amount is readily determined. Blank spaces in the page are paid for as full. Tables and extra work occasioned by words in foreign languages and other unusual styles of printing involve extra pay. In newspaper and job work the amount of composition is found by multiplying the whole number of lines set, measured by a gauge on the type or a proof, by the number of ems in a line. In English printing offices the reckoning is by letters or ens (n), making the thousand one half that of American printers. The time of the compositor is divided between the composing or setting, which takes about two thirds of it, and making up and imposing (which however in American offices are now usually made a separate branch of work), correcting, and distributing. The types after the copies required have been struck off are washed in the forms with lye and rinsed with water till the latter runs off clear. They are then as required returned to their boxes, for which purpose the compositor wets them with a sponge so that they shall adhere together, then places a quantity in his left hand supported by his composing rule, with the nicks upward and the face toward him, takes a few letters between the fingers and thumb of his right hand, and, seeing by a glance what they are, drops them with great rapidity into their proper boxes. If this is not done with accuracy, he suffers loss by the time spent in correcting the errors that will consequently appear in the next matter set up. In a day's work of 10 hours a good compositor will set, correct, and distribute 6,000 ems or 12,000 letters. —*Type Setting and Distributing Machines.* A variety of machines have been contrived for setting type and others for distributing; and a few among them have been put in successful practice. Those best known are the invention of Mr. William H. Mitchel, of New York. Of his type setting or composing machines 10 have for some time been kept in operation in the printing house employed upon this cyclopædia, and also a number of the distributing machines. The former were the first invented, and the latter were especially designed to meet their requirement in supplying the types regularly ranged in ranks, each letter by itself. The type setter is a machine in shape like a harpsichord piano. It is furnished with 54 keys, each one of which is marked with a small letter, point, or space. One capital, I, has also its key. The other capitals and special types are arranged in the cells of a small case back of the keys; and as one of them is wanted it is taken by the operator and dropped into the mouth of a slide by which it is carried on till it takes its place among the others. The types which connect with the keys are piled up on their sides in regular lines on brass slides of which one edge is turned up, and these slides are

ranged across the machine standing nearly vertically. As a key is struck with the finger the type at the bottom of the pile is pushed out edgewise, and falls lengthwise upon a narrow endless tape, which instantly carries it onward back from the operator. There are 84 of these tapes parallel to each other constantly revolving at the same rate; those on the right hand side of the operator are very short, but toward the left there is a constant increase in their length up to 2 feet of carrying surface. As each of them passes round the little brass roller and under the table, the type it carries is tipped off upon a receiving tape, the revolution of which is obliquely across the line of all the others and toward the left. The movement is so arranged, and the distances travelled by the different types are so proportioned, that these must lie along the receiving tape in just the order the keys were struck. The receiving tape at the end of its circuit discharges them one by one upon the periphery of a narrow wheel, which as it revolves leaves them in a standing position and correctly set upon a long brass slide. With each type added the row is pushed along by the wheel the thickness of the type; and when the slide is full, it is placed upon a receiving stand containing 10 cells, and drawn from beneath the type. The slide is then replaced upon the machine. From the receiving stands the types are removed as may be convenient, and made up into lines and pages. By the use of these machines a considerable economy is experienced in the expense of setting.—The distributing machines are used in connection with the composing machines. The types employed are specially prepared by means of nicks differently placed on each letter, but always on the upper or opposite side to that nicked in all types for designating the foot of the letter. The types to be distributed are ranged in a single line in a long channel upon the top of the machine, and by a weight suspended over a pulley they are pushed along this channel as required. At the end one at a time is pushed to one side, and drops into an open slot on the outer surface of a revolving cylinder. In this slot it hangs suspended just so low as the nicks admit, and the lower end projects below the edge of the cylinder a corresponding distance, which is different for each letter. As the cylinder moves round the types are carried on, and each in its turn, when opposite the compartment to which it belongs, is hit upon its lower end by a little projection upon the fixed part of the machine, which throws it out of its place, and causes it to fall down and be received in a standing position upon one of the slides diverging horizontally like radii from the revolving cylinder in the centre. The rows of type as fast as they accumulate, one row in each slide, are pushed along by little levers kept in constant action under the cylinder; and whenever a slide is full it is ready to be transferred to the composing machine. Each of these machines is kept in operation by a belt from a
pulley of the shafting, and they are tende
boys or girls who have had no experien
compositors.—*Stereotype Printing.* The
being distributed after the required num
impressions have been taken, if at any time
copies are called for, the whole must be
set up, proofs corrected, &c. In the case of
ter difficult of correction, and in which
errors might seriously affect the value

dressed by planing the back and edges.
hickness is only about $\frac{1}{8}$ of an inch, and it
therefore in printing to be backed with a
den block to make its surface level with a
e of ordinary type. But it is of convenient
pe for storing away, or for transporting to
ant places to be there used for multiplying
es. It is in this form that, without recom-
ing and without risk of alterations, the
e work may be reproduced almost simul-
ously in New York, London, Paris, &c.
d cuts may be cheaply multiplied by this
ell as by the electrotype process of stereo-
ing, an account of which, as applied to the
eotyping of this work, is given in ELECTRO-
ALLURGY, vol. vii. p. 76. An improvement
duced in this since that account was pre-
d is worthy of mention. A first coating of
per is precipitated upon the powdered plum-
o with which the surface of the types is
ered, by the application of a wash of sulphate
copper, and the immediate sprinkling over
s of fine iron filings or iron dust. A film
copper is thus at once produced, and the
e being then placed in the battery the de-
it of the required thickness is much more
kly obtained.—Though the electrotype pro-
s is the most beautiful and perfect method
stereotyping, it is not found so convenient
practice for the rapid production of large
s, such as newspapers; and the use of
ter of Paris has proved too troublesome for
new application of the art. Stereotyping
large daily papers, though the plates are
d but one day, and are then consigned to the
ing pot, is found to be of great economy by
ing the types from wear in the press, and
urning them to the cases as soon as a single
t is obtained from the forms. A very in-
ous and neat method of quickly obtain-
this cast (devised in France), called the
er process, has been of late applied to
ting the London "Times," and has also
n introduced into New York, where it was
employed in 1861 for the "Tribune" news-
er. The forms are prepared in ordinary
each containing one page of the paper.
ile they are being made up the stereotyper
ares the material for the matrices. For
purpose a sheet of paper of the proper size
d upon a table, and with a brush covered
h an adhesive composition, on which tissue
er is laid; to this are added successively other sheets and coatings of the composition, until a moulding sheet $\frac{1}{12}$ of an inch thick is obtained. The form of type, brushed clean on both sides, being laid upon an iron table and slightly oiled on the face, the moulding sheet is applied to it and beaten with a stiff compact brush until it is well set around the shoulders of the type and assumes an embossed appearance. Woollen cloths are then laid over the matrix and form, and the whole placed on a steam table under a platen, which is tightly screwed down in order to impart to the matrix a perfect impress from the face of the type, and at the same time to expel the moisture from the matrix into the blankets by the heat of steam let into the hollow table. This process occupies but a few minutes, when the matrix, now as pliable as Bristol board, is removed and placed in the mould. This is of iron, made concave with a curve conforming to that of the cylinder upon which the plate is to be printed, with a corresponding convex cover, and under this an iron frame going round the margin of the matrix to secure it in proper shape in its place. When it is made ready the mould is set on one end and the liquid metal poured from a ladle through an orifice in the other end. As soon as possible the plate is taken out, cooled and hardened in a tank of water, and its sprue end cut off by a circular saw driven by steam. It is then placed in a planing machine, face down, protected by a sheet of pasteboard, and the ribs which are cast on the back planed smooth and even. With these ribs the plate is exactly equal in thickness to the height of type, and weighs about 65 lbs. The "New York Herald" uses a much thinner plate, without ribs. It is now taken to a table, where it is finished by trimming the edges with a hand plane, and cutting out with a chisel any portions of metal in the open spaces which are so high as to be likely to black the paper in printing. The average time consumed in stereotyping the forms of the "Tribune" is from 30 to 35 minutes; and its forms have been ready for the press in 20 minutes from the time the last page was given to the stereotyper. A set of the plates secured to the printing cylinders answers perfectly well for an edition of more than 200,000 copies. The same method of stereotyping is also in use to some extent in New York for small articles of press work.—Some of the subjects connected with printing have already been treated under other heads. Thus the composition of printers' ink is given under INK; printing from engraved plates is noticed in the articles ENGRAVING and LITHOGRAPHY; and the processes of calico printing and anastatic printing under their own heads. The nature of the printing employed for the blind is noticed under BLIND.—*Nature Printing.* The art of reproducing upon paper, by the process so called, the exact figures of portions of plants and other objects, has within a few years been brought to great

perfection in Europe, especially in the imperial printing establishment at Vienna. That true pictorial representations of flowers, leaves, &c., might be obtained by impressions upon paper for botanical studies, was suggested in the "Book of Art" of Alexis Pedemontanus as far back as 1572; and in the next century copies representing the structure of leaves, &c., were made by pressing dried plants coated with lamp smoke between two pieces of paper. The botanist Hessel, as stated by Linnæus in his *Philosophia Botanica*, obtained in America figures of plants by impression in 1707; and at a later period (1728–'57) a printing establishment at Erfurt was employed in bringing out the great work of Prof. Kniphof, *Herbarium Vivum*, in 12 folio volumes, with 1,200 illustrations produced by this process, printer's ink being substituted for lampblack. The impressions were then first colored, also in imitation of nature. Other works of similar character were occasionally produced after this in Germany and France. In 1833 Peter Kyhl, a goldsmith and engraver at Copenhagen, made known a curious method he had employed of ornamenting silver plate with copies of natural objects, obtaining the forms by impressing these objects upon the metal by means of two steel rollers; and at the exhibition of industry held at Charlottenburg in May, 1833, he produced a number of beautiful specimens of this work. He prepared an account of the process, and illustrated it with printed copies of leaves, feathers, lace, and other fabrics, the scales of fishes, and serpent skins. He experimented with plates of copper, zinc, tin, and lead. With the last the impressions were admirable, but the metal was not suitable to print from, as it soon became obscured by the printers' ink. In 1851 Dr. Branson of Sheffield, in a paper read before the society of arts, announced his having experimented with the electrotype process for producing plates of a harder surface. He also had obtained in gutta percha impressions of parts of plants, and, using the gutta percha as a mould, had reproduced the figures in brass. Prof. Leydolt, of the imperial polytechnic institute at Vienna, as early as 1849 had directed his attention to the production by similar means of correct copies of the polished surfaces of agates and various fossil remains. The agates, he found, when etched with fluoric acid, were acted upon by the acid unequally upon the different lines, and the surface being then inked, a faithful impression of the lines could be taken. But he perfected the process by taking the impression in a plastic composition and electrotyping this, thus obtaining suitable plates for printing from, as in the electrotype applied to stereotyping. In the same institution impressions were taken in 1852 of lace on plates of metal, and by the suggestions of Haidinger and Abbate portions of plants, polished sections of wood, &c., were copied by pressure upon plates of lead, which, being afterward moderately heated, were easily
freed from the fragments of the more
objects. An electrotype was then
copper, which, excepting the colors,
perfect facsimile of the original. To
the colors, these were applied to the

rails, and on these rails is a carriage calle
bed. The bed is intended to receive the form
type on its upper surface, and is in conseq
made of hard wood or of stone, and

ned. The bed is moved alternately from end of the table, where it stands under platen, to the other end, by means of a ll axle placed crosswise under the bench, l provided with a crank on the side where pressman stands. On the end of the bed thest from the platen is hinged a quadrangu- frame of wood or iron called the tympan, l on the end of the tympan is hinged an- er frame called the frisket. The outer edge the tympan is solid; the inside is of cloth parchment doubled, with a woollen blanket ween. The frisket is a similar but more nder frame, filled in with a piece of thick er, and its object is to hold the sheet to be nted against the tympan. The object of the pan is to carry the sheet and to form a surface between the paper and the platen, as to equalize the pressure. It also serves register; that is, it carries marks or pins by ans of which it is easy to place the sheets ays in the same position, and thus have the rgins all equal and the printing correspond both sides. The press is also provided with counter weights, the one to raise the plat- the moment the pressman lets go the lever, other to turn back the axle and bring the l under the press to the end of the bench ich is free. There is an inking table con- ing of a flat surface, with two elastic balls, e for each hand, about 8 inches in diameter, vided with a short handle and covered with skin, which was most effective when partly ten. A small quantity of ink was placed on inking table and spread in a thin layer, ence it was taken up evenly on the balls by ing and rocking them on the table and inst each other, and then applied to the e in a similar manner, each time an impres- n was to be taken. The manner of using hand press is as follows. The form is made on the bed in the proper position, and the pes are inked. The frisket is folded on the pan, and the tympan is folded on the bed, that the frisket is between the types and the pan. The bed is brought under the platen, this last is pressed down by pulling on the er. Then the pressman lets go the crank the lever, when the counter weights will e the platen and bring the bed from under The pressman unfolds the tympan and the ket, and finds on the last an impression n the types. All the portions of the frisket ich have been printed upon are cut away, all is ready for printing, which is effected ist described, after placing the sheet to be ted between the tympan and the frisket. hand press of the kind described was gener- y worked by two men, the one attending to inking, the other placing the paper and ing on the lever to make the impression; they were able to produce 200 copies print- on one side per hour. The first improve- nt on the hand press was made in England Earl Stanhope, in 1815. It consisted in ilding the whole of iron, and substituting for the screw an obtuse-angled jointed lever, producing a progressively increasing pressure. The second improvement was made about the same time by G. Clymer of Philadelphia, who also used iron and a combination of levers; his press was called the Columbian. The third improvement is due to M. Gannal, a glue manufacturer of Paris, who, being applied to by a printer named Chegaray for a substitute for the putrid dog skin balls, devised the gelatine rollers, made of a mixture of molasses and glue, which are now universally used. With these improvements, and the minor devices which have been introduced since that time, it is now possible to print by hand at the rate of 250 impressions an hour.—Toward the end of the 18th century it was already felt that the hand press would soon be much too slow for the wants of the craft, and inventors began to devise presses to be moved by power. The first published invention in this department is that of William Nicholson, patented in England in 1790. The types were placed around a revolving horizontal cylinder, and were inked by rolling against another cylinder revolving in contact with the first. The ink was distributed on the inking cylinder by means of several inking rollers, the last of which revolved near the ink fountain. A third large cylinder covered with felt, and revolving in contact with the first, produced the impression, which was thus made by rolling the sheets of paper between two cylinders. Nicholson failed in attaching the types to the cylinder, and gave up his plan; but had he succeeded in this particular he would have found his inking arrangement entirely impracticable, the gelatine rollers as yet not having been invented. Friedrich König, a printer of Saxony, began to devise improvements in printing presses in 1804. Finding no help from capitalists on the European continent, he went to London, where he succeeded in interesting Messrs. T. Bentley and R. Taylor in his views. In 1811 he obtained a patent for working an ordinary hand press by power, but this failed in practice. Messrs. Donkin and Bacon, after experimenting for several years, succeeded in 1813 in building for Cambridge university a machine on Nicholson's principle, but for the type cylinder was substituted a quadrangular solid, on the 4 flat faces of which the types were placed, and wedged tight, as on the table of the ordinary hand press. The inking rollers had a lateral motion, so as to be always in contact with the types, and the printing cylinder was indented longitudinally in 4 places to receive the corners of the type carrier, and was cam-shaped so as to press the paper against the types. This machine was found too complicated in general, and the inking arrangement was unsatisfactory. Meanwhile Mr. König, with the help of A. F. Bauer, likewise a German, a native of Stuttgart, and a machinist by trade, had discovered that the way to make a press with a flat bed work rapidly was to apply

the pressure with a cylinder instead of a flat surface; he built a machine secretly, and on Nov. 28, 1814, "The Times" newspaper of London informed its readers that they were reading for the first time a sheet printed by steam. In this machine the form of types was made to move horizontally under a printing cylinder; the inking apparatus was placed in front of the printing cylinder; the ink was in a long horizontal cylinder, and by means of a tight piston was made to drop regularly through small holes on the under part of the cylinder between two iron rollers, from which it was distributed by other rollers, having a rotary and a longitudinal motion, to two larger rollers covered with leather, under which the form moved to be inked. This first press was further improved by placing a printing cylinder on each side of the inking rollers, thus getting two copies for each change of motion of the form. The number reached was 1,800 impressions per hour. Mr. König soon after made a machine for printing both sides, which was nothing more than two presses combined in one, the paper being carried from one to the other by S-shaped tapes. The inking arrangement of König's machines was far from perfect, sometimes losing two hours in getting started. Mr. Cowper in 1815 patented a process for curving stereotype plates, and fastening them on a cylinder; but the most important part of his patent was the invention of the inking table. The cylinders were about 5 feet in diameter, and only a small portion of the periphery was covered by the stereotype plates, the rest being used for distributing the ink. For this purpose several distributing rollers were disposed over the type cylinder in a frame movable on hinges, in such a manner as to come successively in contact with the types and with the part of the cylinder of a smaller diameter used as a distributing table. The ink was carried from the fountain to the table by another set of inking rollers. A few of these machines were built for and used at the bank of England. The next improvement was made by Cowper, associated with Applegath; it consisted in applying the distributing table to a flat bed press; part of the bed supports the types, and the other part serves as the distributing table. These machines were perfectly successful, and are now used all over the world. Some have one cylinder and print one side, and some have two cylinders and print on both sides. The momentum of the moving bed is overcome at each end of the stroke either by metal springs, or by an air spring consisting of a piston attached to the frame entering a cylinder attached to the moving plate. In 1838 a faster press was built for the "Times" on the same principle by Cowper and Applegath. By reducing the size of the printing cylinder to 6 inches diameter, they succeeded in crowding 4 into the same space previously occupied by 2, thus producing twice as many copies with the usual velocity. These printing cylinders were fed by means of tapes from feeding boards overtopping each other. This machine
off 6,200 copies per hour, and worked da
more than 10 years.—While they were p
ing cylinder presses in England, Isaac Ad
of Boston, Mass., took up the problem sta
ed by König of working a hand press by
and succeeded in making the machine de
in his patents of 1830 and 1836. The pl
stationary; the bed, situated directly u
the platen, has an up and down motion
few inches, but no horizontal motion. In t
of the bed is a large inking roller re
constantly. The tympan has a horizon
tion, and carries a small inking roller w
is brought at each stroke in contact with
large inking roller, and rolls back over
types. The tympan is also provided wi
fingers which take hold of the edge o
sheet to be printed, and carry it betwe
bed and the platen. The printed sheet
ried away by tapes, between which the
of the paper is blown by means of a blow
an air pump. The printed sheets are take
the tapes and piled up by a fly, a sort of
made of light wood, and carried on a r
shaft. The prongs of the fork, which
long as the sheet is wide, enter betwee
tapes, and, at the proper moment wh
sheet is above them, rise suddenly, desc
a half circle, and depositing the sheet o
receiving table on the other side of the r
shaft. Among the secondary devices in
Adams's press, the most important is an ar
ment for instantly disconnecting the rod w
connects the bed with the main shaft, by
ing down a pedal which is under the f
the feeder. Thus, if the feeder is not r
with the sheet, he presses the pedal, and
bed being disconnected remains stationary.
back printing is avoided. These press
worked at three different velocities, and
age 900 copies an hour.—The object of th
ventors of power presses was speed, and
this reason several attempts were mad
carry the types on a cylinder, and thus sub
tute a continuous for an alternate motion
the bed. It was reserved for an American

rollers, the distributing table, the fly, and
the improvements in the processes of wor
metal and building machines in general.
10-cylinder presses, such as are used in N
York and London by the leading journals, s
off 15,000 impressions per hour. They
only employed for newspapers of large circ
tion.—The hand press most used in the U
States is called the Washington press;
a Stanhope press very slightly modified

Samuel Rust of New York, who obtained a patent in 1829. In England they use the imperial and the Columbian. In Germany and France they have other appellations for nearly the same thing. Hand presses are used in large offices where very fine and perfect work is wanted, or when very few impressions are to be struck; and they are used in small establishments where a power press is not required. The Adams press is used for fine printing; while the cylinder press is employed for common book work, for jobs, and for newspapers of small circulation. This machine is in great favor with printers from the fact that it gives good impressions when worked slow, though it can be worked very fast and still produce legible printing.—In the patent records of Europe and America will be found descriptions of many presses which we have not mentioned. Some have been built and used for a time, and some include important devices which may be of service for future improvements. The press used for taking impressions from engraved plates consists of two parallel rollers pressing the plate and the paper between them. The rollers are turned by cranks. Another kind of printing machine was invented in 1858 by Dr. S. W. Francis of New York for the use of the blind. It consists of a key board, each key acting on a hammer on which a letter is engraved. The letters are printed on two movable sheets of paper, two copies being produced at once.

PRINTING, Calico. See Calico.

PRIOR, the superior of a convent of monks. A claustral prior is one who governs under an abbot, by whom he is removable at pleasure; a conventual prior is one who has no officer over him, and his convent is called a priory.

PRIOR, Matthew, an English poet, born at Wimborne-Minster, Dorsetshire, July 21, 1664, died at Wimpole, a seat of Lord Oxford, Sept. 18, 1721. He was educated at Westminster, under Dr. Busby, and at St. John's college, Cambridge, where he was graduated in 1686. Here he formed an intimacy with Charles Montague, afterward earl of Halifax, with whom he wrote "The City Mouse and Country Mouse," in ridicule of Dryden's "Hind and Panther." In 1691, through the influence of the earl of Dorset, he was appointed secretary of the embassy at the Hague, and so recommended himself to the favor of William III. that he made him one of the gentlemen of his bedchamber. When Queen Mary died in 1695, Prior wrote an ode upon the event, and in 1697 was appointed secretary of the commissioners who concluded the treaty of Ryswick. In the following year he was employed as secretary of the embassy at the court of France. In 1699 he was made under secretary of state, but losing his place shortly after, received in 1700 the appointment of commissioner of trade. In 1701 he was a member of parliament from East Grinstead, and soon after changed his politics, becoming a violent tory. He celebrated the victories of Blenheim and Ramillies in the opening years of the reign of Queen Anne, and in 1711 was sent on a private mission to Paris with proposals of peace. The negotiations began at Utrecht, but proceeded so slowly that Bolingbroke went to Paris as ambassador to hasten them; and Prior, who was in company with him, after Bolingbroke's return became the ambassador, but did not publicly assume the title until the departure of the duke of Shrewsbury, who "refused to be associated with a man so meanly born." When, in Aug. 1714, the whigs had regained office, Prior, was recalled, and had no sooner returned than he was arrested on a charge of treason. For two years he remained a prisoner in his own house, and employed his time in writing "Alma, or the Progress of the Mind." After his release he had no fixed means of subsistence except his fellowship at Cambridge, but he was rendered comfortable for life by publishing his poems by subscription, through which he realized 4,000 guineas. He was buried in Westminster abbey, and a monument was erected to his memory, for which he left £500 in his will. After his death a "History of the Transactions of his Own Times" was published (2 vols., 1740); but although Prior had been making preparation for such a work, there was little in it of his.

PRISCIANUS, a Roman grammarian, who lived about the latter half of the 5th century A. D. From his surname Cæsariensis it is supposed that he was born or educated at Cæsarea. He was a pupil of Theoctistus, and taught grammar at Constantinople. No other particulars of his life are known. His work on grammar is entitled *Commentariorum Grammaticorum Libri XVIII.* It contains a large number of quotations from Greek and Latin writers not otherwise known, and a parallel between the Greek and Latin languages. He also wrote a "Grammatical Catechism on 12 Lines of the Æneid;" a "Treatise on Accents;" one on "The Metres of Terence;" and some short poems, beside several translations from the Greek; and the acrostics prefixed to the plays of Plautus are ascribed to him. His name is familiar in the phrase *diminuere Prisciani caput* (to break Priscian's head), commonly applied to those who use false Latin.

PRISM, in geometry, a solid bounded by plane faces, of which two that are opposite are equal, similar, and parallel, and are called the bases of the prism; the other surfaces are parallelograms. The axis is the line connecting the centres of the bases. The prism is triangular, square, pentagonal, and so on, according as the figure of the bases is triangular, square, pentagonal, &c. It is right or oblique according as the sides are perpendicular or oblique to the bases. A right prism is regular when its bases have the figure of a regular polygon. The prism corresponds among bodies with plane surfaces to the cylinder among bodies with curve surfaces.—In optics, a prism is a portion of a refracting medium bounded by two plane surfaces inclined to one another. The line in which these two surfaces meet, or would meet if produced, is the edge of the prism; their inclination is called its refracting angle. The form commonly used is a triangular prism of glass. A good contrivance for delicate experiments may be made with two rectangular pieces of plate glass firmly set to form two sides of a triangular box which is to be filled with water or spirits of turpentine. The prism is an essential part of all apparatus for decomposing light.

PRISON, a building used as a place of penal confinement and safe keeping. From the earliest periods we find references to the prison, not as a place of punishment, but as a place of custody and detention. It is first mentioned in Gen. xxxix. 20, where Joseph's master is said to have "put him into the prison, a place where the king's prisoners were bound." The Philistines put Samson in prison, "and bound him with fetters of brass, and he did grind in the prison house." There is no evidence that the Jews had any prisons till the times of Ahab and Asa, and even then their prisons were, like those in most of the oriental countries from that time to the present, strong rooms or dungeons in the residences of high officers of state. The Greeks had a great repugnance to prisons, and debtors to the state were the only persons detained in them, except those awaiting trial. After the Romans conquered Greece and the countries adjacent, the prison seems to have been sometimes used as a house of detention and temporary confinement, something like our police prisons; such was probably the case with the prison at Philippi, whence Paul and Silas were released by a miracle. In Rome, the most diligent antiquarian research has been able to discover but one prison, that now known as the Mamertine caves, and supposed to be the same mentioned by several classic writers as the Tullian prison. It consists of two rooms or vaults, one 33 feet by 22, the other a semicircle of 22 feet radius. They were close and not ventilated, and life could have been preserved in them but a short time. They were mainly used for prisoners awaiting speedy execution. Tradition asserts that St. Paul was confined here just before his death. There was another class of houses of detention, called *ergastula*, very numerous in Rome, which were used for the safe keeping of slaves. The usual mode of detaining a prisoner for trial was by chaining him by the hand to one or two soldiers; and convicts were banished to an island, or condemned to the quarries or the mines. The Justinian code makes but slight allusion to prisons; its penal inflictions were tortures, mutilation, or death. Cicero had said 6 centuries before: *Carcer non ad puniendos, sed ad continendos homines habui debet;* and the jurists of the later Roman empire agreed with him. It was forbidden to imprison women or soldiers; and the prison was regarded as only of occasional service, for temporary custody. The early Christians visited the inmates of the prisons, whose condition was often wretched enough, ministering to their wants, and even paying for the privilege of admission. At a later period the *fratres misericordiæ*, a benevolent order of monks, made this one of their duties.—The loss of caste in its three degrees, namely, of family position and authority, of citizenship, and of liberty, either of which might be inflicted as a punishment for crime, obviated to a great extent the necessity of imprisonment, either temporary or permanent, in the Roman empire. No such substitute, however, would answer the purpose of the feudal barons, who, on the dissolution of the western empire, became rulers over small districts of territory. They required strong castles to protect their territory from their enemies, and in the principal tower of these, called the *donjon* (whence our word dungeon), they generally built rooms for the confinement of their captive foes or refractory retainers. They did not attach the idea of punishment to this durance; that was inflicted by torture or starvation. These prisons were sometimes cut out of the solid rock, far below the surface of the earth, and being dark, often damp, and with little or no means of ventilation, it is astonishing that life could have been so long protracted in them as we know it sometimes was. There was a class of these dungeons intended to destroy life by the combined influence of starvation and suffocation. They were small and bottle-shaped, with narrow mouths at top, and the prisoner was let down into them. They were called *oubliettes*, or *vade in pace* (go in peace). The provisions of *Magna Charta*, protecting the subject from imprisonment otherwise than by due course of law, were intended to prevent arbitrary detention and cruelty; and the principle, once acknowledged, was insisted upon in numerous subsequent concessions wrung from the earlier kings of England, and in *habeas corpus* acts passed by parliament at a later date. The object of these acts was to protect the accused from long detention before trial, and the convict from neglect and cruelty while awaiting his sentence or execution. These objects, the latter especially, were not wholly accomplished, for, owing to the faulty construction of the prisons, which were mostly the castle dungeons, and the numerous abuses which had arisen, the most atrocious cruelties were practised, especially upon imprisoned debtors, as late as the reign of George I., and had not wholly ceased till the reign of George IV.—The idea of substituting confinement in prison for corporal violence dawned very slowly on the minds of legislators. Even Sir Edward Coke, in his "Commentaries," declared that the prison was a place of safe custody, not a place of punishment. The poor debtor, however, had long found that to him it was a place often of most cruel punishment, accompanied, when the malice or avarice of the keeper prompted, by tortures so horrible as almost to surpass belief.

In the reign of George II. a parliamentary inquiry was instituted into these abuses, which led to the indictment of two of the principal gaol keepers of London for murder. In the latter part of the 18th century John Howard commenced his investigations into the condition of the English prisons, the first results of which appeared in two acts of parliament passed in 1773, one abolishing prison fees (which up to that time had been exacted from all prisoners), and the protracted confinement of the prisoner until these were paid; the other providing for an improvement of the sanitary condition of gaols. In 1777 appeared the first work of Howard on prisons, "The State of the Prisons in England and Wales." The works of Beccaria on crime and punishment appeared about the same time on the continent; and in England Sir William Blackstone, Mr. Bentham, and Mr. Eden entered upon the work of prison reform in earnest. It was found that the most hardened criminals, and those comparatively innocent, and indeed often witnesses and persons falsely accused, were placed together without employment in a common room; that in some cases the two sexes were confined in the same cells, and usually the most depraved prostitutes were permitted to associate with girls hitherto chaste; that the gaol keepers were permitted to sell liquors to the prisoners, and often for money permitted the commission of gross crimes within the prison walls; that in consequence the prisoners confined for petty offences left the prison thoroughly educated in crime; that the prisons were badly ventilated and very filthy, and that gaol fever, a disease of terrible malignancy, often prevailed, causing at one session of the court, known as the "black assize," the death of 300 persons, among them the judge, jury, several of the lawyers, and other officers of the court; and that debtors often fell victims to this fever, and spread it through the visits of their families to other neighborhoods. Attempts were made to remedy these evils, by building better arranged gaols, which, by isolation of the prisoners, ventilation, and thorough purification, should prevent such disastrous results; but the government was occupied with transportation schemes, and these projects fell through. Early in the present century Mrs. Elizabeth Fry commenced her mission to the female prisoners in Newgate; and in 1818 Mr. (afterward Sir T. F.) Buxton published an "Inquiry whether Crime and Misery are produced or prevented by the present System of Discipline." From this work it appears that, notwithstanding Howard's exposures, Mrs. Fry's revelations, and the developments made by the committee of aldermen of London in 1815, the abuses of Howard's time still continued, and had in many particulars increased, and that a radical and thorough change was needed. In the conclusion of his "Inquiry," Mr. Buxton laid down certain principles as to the rights of the prisoner and of society, which, though in advance of his time, are of general application, and well worth quoting. A prisoner, even if convicted of serious crimes, he conceived to be entitled to pure air, wholesome and sufficient food, protection from cold, opportunities of exercise, the privilege of labor, and the devotion of a part of the proceeds of that labor to the support of his family, if he has one. Society has a right to demand that the prisoner shall be securely confined, and that he shall not be made worse either in body or character by his imprisonment; that his intemperance or other evil habits shall be restrained; and that education and religious instruction shall be provided for him. Mr. Buxton's remonstrances were more immediately effective than those of Howard and his coadjutors. The great penitentiary at Millbank, which holds 600 male prisoners, was commenced in 1819; and a committee was appointed in 1822 to revise the statutes concerning gaols and prisons in England and Wales. In 1835 an act was passed providing for inspectors of prisons to be appointed by the government; a law which has been of great benefit in opening the way for improvements in prison management and discipline. The Parkhurst prison for juvenile offenders was erected in 1838. In 1842, after examination of prison systems in other countries, the Pentonville prison was built as a model prison on the separate plan. Government prisons have since been erected at Portland, Portsmouth, Dartmouth, Chatham, and Brixton. The hulks of men-of-war, laid up in ordinary, were for a time used as prisons, but have now been abandoned as every way objectionable. Scotland, once much worse than England in the abuses of her prisons and the laxity of their discipline, has since 1839 been thoroughly reformed. In Ireland there has been much improvement in the prisons since 1826, though now there is more liberty allowed to the prisoners than would be deemed consistent or desirable in other countries.—Transportation, which is really a species of imprisonment, is so intimately connected with the history of prisons and prison discipline in Great Britain, that some account of it is necessary to a full understanding of the subject. The first instance of transportation of convicts from Great Britain occurred in 1619, when 100 were ordered to be sent to Virginia, and afterward small numbers were occasionally sent out and sold to the planters for 7 or 14 years, a practice often alluded to by Defoe and other writers; but the business was not conducted systematically till after the year 1718, when for a number of years as many as 2,000 convicts were annually transported thither. These were sold to the settlers for a term of years, and at the expiration of their time often became landed proprietors, and purchased the services of other convicts. The war of the revolution put an end to this traffic, and the British government was compelled to find a new outlet for its convict population. In 1786 it was determined to establish a penal colony in Australia, and the first cargo, of 850 convicts, was sent out in March, 1787, to Port Jackson, near Sydney. For some years there was nothing but disaster connected with this transportation. The convicts, stowed in large numbers on transport ships, died by hundreds of fever on the passage out; or if they arrived they were unable to earn a subsistence, and perished of famine, or, to preserve life, adopted the savage habits of the native bush rangers. At length the influx of free settlers, the extensive sheep culture, and the building up of large towns, made their condition tolerable; while the grants of lands to the emancipists, as those who had served their time were called, and the plan of allowing tickets of leave, which in some cases shortened their term of punishment almost one half, soon gave to the convict settlers a powerful and for a time predominating influence in the colony, which was exerted for evil. This led to the organization among the free settlers of a party opposed to transportation, which eventually became so powerful that the home government was compelled to yield to their demands, and in 1840 transportation to South Australia ceased. It was maintained on Van Diemen's Land till 1848, and in North and West Australia some time longer; but, with the exception of 200 or 300 sent to western Australia, it has now been entirely abolished. Its discontinuance involved considerable difficulty at home. The government was under the necessity of materially shortening the sentences of those who were committed to prison at home, instead of being sent to Australia; and the introduction of a ticket of license system, intended to watch over their conduct during the period which would have elapsed if they had been transported, produced a panic in the English community in 1855 and 1856. Of the convicts, of whom there are somewhat more than 6,000 in all, 3,300 or 3,400 are employed on the public works at Portsmouth and Portland, and in the dockyards of Dartmouth and Chatham. The remainder are in the Pentonville, Brixton, and other prisons.—In France, prisons were not recognized as places of punishment until after the revolution. Previous to that time, the galleys, the wheel, and the chain gang had been the principal modes of punishment. The prisons were as badly managed and as objectionable in their construction as those of England until after the restoration. Before this they had been of three kinds, the royal prisons, the prisons of the nobles, and the official prisons; and the greater part of them were castle dungeons. Within the last 25 years many new prisons have been built, and improvements have been made, but there is still freedom of intercourse between prisoners in most of them, and no labor except for convicts. The prisons of the country are now divided into 5 classes, viz.: 1, police prisons; 2, houses of arrest for those awaiting trial or sentence, and for those imprisoned for less than a year; 3, judicial prisons, for cases of appeal from the lower courts, for those imprisoned at the pleasure of the court, and for cases awaiting the judgment of the court of assizes; 4, houses of correction for juvenile offenders, and children whose parents are convicted of crime; 5, central prisons, or houses of detention and hard labor, answering to our state or convict prisons. There are 29 of the last. In all of them the contractor or his agent is allowed to keep a shop on the premises, and supply the prisoners with whatever they wish; and in the central prisons the prisoner has half his earnings to spend in this way, while the other half is reserved as a fund to be paid him at his discharge. The prisoners not frequently form associations in prison to carry on extensive robberies after their release, and the money they receive at their discharge affords facilities for this. In 1848 labor was abolished in all the prisons, on the ground that it interfered with the industry of honest citizens; it was reëstablished in 1852, but the products of the labor are purchased by the state for its public institutions. In 1852 transportation to Guiana and Lambessa in Algeria was introduced, and is still the principal punishment of political offenders.—In Germany generally the prisons are said to be well managed. In Prussia the management of all the prisons of the country has been confided, since 1850, to Dr. Wichern, the founder of the inner mission and the rough house reformatory at Horn, who, as inspector-general, with full powers, has improved the discipline, and placed over each a warden or director, and subordinate officers trained for the purpose, and selected with great caution and discrimination, in the belief that more depends upon the personal character and adaptation to their work of the keepers of prisons than upon systems of discipline, forms of buildings, and all other arrangements together. The results which have followed these changes are said to be in the highest degree satisfactory.—In the United States, the prison has been considered a place of punishment almost from the first settlement; and though mutilation, branding, and corporal punishments prevailed in the early history of the country as penalties for some crimes, and still find a place on the statute book of some states, they are now seldom inflicted. The convict prisons were in a horrible condition prior to the revolution; but since 1786 reforms have been going on in the larger states, and most of the state prisons would compare favorably, probably, with those of most other countries, though in some of them cruel punishments are yet resorted to, and too little discrimination is used in the appointment of wardens and keepers. The larger cities have usually penitentiaries for the punishment of offenders sentenced by the municipal courts, as well as houses of detention or police prisons, to which those awaiting trial r sentence are committed. These are generally well constructed. The gaols erected by the counties are in many instances badly constructed, injudiciously situated, and in charge of unfit keepers. The efforts of the New York prison association, the late Boston prison discipline society, and the Philadelphia society for alleviating the miseries of public prisons, and their reports of the condition of the prisons and gaols throughout the states, have been productive of much good in the diffusion of correct notions on the construction and management of these institutions; and where new prisons are erected, they are generally constructed on better models.—When, in the latter part of the last century, imprisonment came to be regarded as in itself a punishment, and as such entitled to take the place of the cruelties and indignities which had previously been inflicted upon the person, the question of the best plan of organization and discipline for such institutions at once became one of great importance. Men like Beccaria, Howard, Blackstone, Bentham, and Eden, at once perceived that the congregation of a number of prisoners in the same room, by day and by night, with no restraint upon their intercourse with each other, and no employment, took away from the vicious much of the terror of imprisonment, corrupted the inexperienced and comparatively innocent, afforded opportunity for education and combination in crime, and, instead of reforming the offender, turned him loose upon society at the expiration of his sentence a tenfold greater villain than when he entered the prison. While these evils were acknowledged, the most effectual remedy for them was not so easily devised. Various plans for the construction and management of prisons were proposed, but all, though containing many excellent features, were liable to serious objections. Mr. Bentham published in 1799 a plan of what he called a panoptic prison, in which every prisoner was to be confined in a separate cell, and each cell was so arranged as to be under the constant inspection, night and day, of guards in a central tower. This in its practical working was found to be a failure, and its ingenious author himself, we believe, admitted it to be so. Howard suggested some improvements in construction, which, though a material advance upon the prisons of his day, have proved defective in some particulars. One of the worst errors in his plans was the provision for lodging three prisoners in one cell. To devise the best plan for accomplishing the objects desired in imprisonment, safe keeping, moderate expense, determent from crime, maintenance of health, and the reformation and moral and intellectual improvement of the prisoners, has been a matter of earnest study and investigation on the part of many philanthropic and intelligent men, both in Europe and America, for the last 40 years. The first plan adopted, when public attention was called to the evils of congregating prisoners in masses without employment, was the solitary prison, first tried in the prison connected with the hospital of San Michele at Rome in 1703, but little known prior to the experiment in the Walnut street prison at Philadelphia in 1786. The peculiarities of this system were the complete isolation of the prisoner from all human society, and his confinement in a cell of considerable size, so arranged that he had no direct intercourse with or sight of any human being, and no employment or instruction. The quiet and order which were substituted for the disorder of the previous want of system, commended it at first to the public mind; and other prisons on the same plan, but less liberal in the size of their cells and the perfection of their appliances, were erected in Massachusetts, New Jersey, Maryland, and some of the other states; and in some instances, where it was not adopted for all the prisoners, cells on this plan were constructed for the worst criminals. But experience soon demonstrated that there were very serious objections to it. A considerable number of the prisoners fell, after even a short confinement, into a semi-fatuous condition, from which it was next to impossible to rouse them; others became violently insane; others still committed suicide; while those who stood the ordeal better were not generally reformed, and in most cases did not recover sufficient mental activity to be of any subsequent service to the community. The great cost of prisons constructed on this principle was another objection to it; and the prisoners being entirely unemployed, the whole charge of their maintenance came upon the state. It became evident that some changes must be made in the system. The "separate" system was originated by the Philadelphia society for ameliorating the miseries of public prisons, founded in 1787. Retaining the plan of continuous cellular confinement, it permits the prisoner to work in his cell, in some instances even encouraging him by reward for overwork; furnishes him with books, both for reading and study, and permits him to receive instruction in his cell, or, as in Pentonville, England, in a general school room, where however he is not permitted to see, though he may hear, his classmates; provides, under similar restriction, for his attendance upon a prison chapel, or at least allows the chaplain to preach in the corridor, so that all can hear at the same time; in some instances gives him a little garden to cultivate, and thus supply himself with some luxuries; permits the visits of the officers, chaplain, &c., to his cell, and to some extent of other people; allows him to correspond under supervision with his friends; and, at Pentonville and some other prisons of the class, provides such comforts and appliances in his cell as make it in itself more comfortable even than the sleeping rooms of persons of the middle classes generally. The advantages of this system are represented to be, that it individualizes the convict, and prevents his recognition by other prisoners who are confined with him, and who after his discharge might attempt to compel him to vicious courses by their knowledge of his previous disgrace; that it renders a large force of guards unnecessary, since combinations and conspiracies are impossible; that it also prevents his degradation by those severe personal indignities which are regarded as indispensable in congregated prisons; and that it gives him more opportunity for instruction and reformation, to which end the good influences to which he is subjected are supposed to contribute. Under this system, the general health of the prisoners is very good, and the mortality is less than in most congregated prisons. Insanity is not, according to the statistics of the past few years, any more prevalent among those confined in these prisons than among those in congregated prisons, and perhaps not quite as much so in this country. The first cost of construction, however, is even higher than in the solitary system, and the labor, though serving to occupy the mind of the prisoner, and defraying part of the cost of his subsistence, is still unprofitable, nowhere covering expenses. In Pentonville, in 1849, the average cost of supporting prisoners (including all expenses) is stated by Mr. Dixon at $250, while the earnings were less than $13. The Pennsylvania prisons do much better than this, but are still conducted at a heavy loss. While the prisoners are obedient and docile, quiet and well behaved, they lose to some extent their mental activity, and on their discharge a considerable number of them sink down into a semi-fatuous state, even when their confinement has been only of 18 months' or two years' duration. This occurred to such a degree at Pentonville, decidedly the healthiest and best managed of these prisons, that when the men, after 18 months' imprisonment, were removed on shipboard for transportation, they were found entirely incapable of taking care of themselves, becoming in a day or two light-headed, low-spirited, silly, and some of them subject to sudden faintings; and it was found necessary, for some weeks before shipping the subsequent companies, to bring them into association with each other, and encourage them to talk and be merry. Nor has it been found that, in cases of discharge, the reformations were so numerous as was to be hoped. If they retained sufficient vitality and intellect to be active, their activity has very often been for evil; if they were stupid and idiotic, they remained so.—The "silent" or Auburn system did not originate at Auburn, for in 1772 Howard saw it in practice at Ghent, and spoke of it approvingly. Not long after, however, this plan was abolished there by the emperor Joseph II., and the old *régime* reinstated. There is, however, little reason to suppose that Capt. Elam Lynds had any knowledge of the prison at Ghent, when in 1823 he made his experiment at Auburn, which up to that time had been managed on the solitary system. It is the purpose of the Auburn plan, equally with those we have already described, to prevent that intercourse between prisoners which experience has shown to be so productive of evil. It attempts to accomplish this by solitary confinement in cells at night, and by strictly enforced silence during the day in the workshops and the chapel. They are permitted, however, to address necessary inquiries to their instructors in the shops, and to the wardens and keepers, to converse with the chaplain, and to participate in the exercises of the Sabbath school, and in singing in public worship. The advantages of this plan were, a much less cost of construction, as the cells, having grated doors, and being only used as lodging and Sunday rooms, could be much smaller; greater efficiency and productiveness in labor, the result of working together, in many cases rendering the prison self-supporting, or even profitable to the state; and, it is stated in some prisons, a better physical and mental condition of the men on their discharge. It is also urged, though hardly demonstrated, that under this system moral and religious instruction can be more effectually conveyed. It is objected to it, that the prisoners know each other, and find means of communicating with each other; that there are consequently frequent outbreaks, which are impossible under the other systems; that the prisoner is more at the mercy and caprice of his keeper than in the other systems; and that the results, so far as escapes, deaths, and cases of insanity show, are less satisfactory than in the separate system. It is obvious that much more must depend upon the character and ability of the warden and keepers in this system than in those which we have previously described. The Auburn system, with some variations in matters of detail, and more or less strictness in the enforcement of silence, is now adopted in the state prisons of most of the United States, and in the principal penitentiaries or district prisons. It is also adopted in a considerable number of the county prisons, especially the larger and more recently erected. In England it is the system generally preferred in the county prisons and penitentiaries. It is also adopted in the 29 convict prisons (*maisons centrales*) of France. In Ireland, Belgium, Holland, Denmark, Sweden, and Norway, on the contrary, the separate system has the preference; while in Germany both are in use. In Italy there is very little system or order in the prisons, except in Sardinia, where some years since the separate plan was received with the most favor.—In England the relinquishment of transportation has been followed by some modifications of the systems we have described. These are due mainly to the influence of Major-General Sir Joshua Jebb, who has since 1837 devoted much attention to the construction and management of convict prisons, and is now chairman of the board of convict prison directors. His system recognizes 3 periods of probation for prisoners. 1. Imprisonment in a separate prison for 9 months. Prisoners are sent, when convicted, to Wakeield, Leicester, or Millbank, and thence drafted o Pentonville, where the separation is less severe than formerly, the prisoners seeing each other in the *yards* and chapel. 2. Associated labor, or penal servitude on the public works, at Chatham, Portsmouth, or Portland. The prisoners work in gangs at the quarries, docks, or fortifications by day, but are confined in separate cells at night. 3. A ticket of leave in W. Australia, or labor on free ground and in ordinary clothes, and lodging in barracks, under surveillance, at home. In all these periods, gratuities in food and money, the latter payable partly at their discharge, and partly, if their deportment is correct, 3 or 6 months after, are attainable by good conduct and industry. Marks of good conduct also shorten by some weeks or months the term of punishment. The system is well administered, but its results are unsatisfactory. The cost per head for the support of convicts is over $190, while their earnings do not exceed half that sum; there are frequent violent outbreaks at the government works, 7 occurring the past year, and the recommitments, amounting to nearly 25 per cent., though due in part to the better fare, &c., in the convict prisons than in the gaols, do not speak well for the reformatory influence exerted. The whole number of convicts in the 10 English prisons in May, 1861, was 7,065. The Massachusetts state prison has adopted a plan somewhat analogous to this, but a little more favorable to the prisoner. By continued good conduct, a prisoner may be credited with from 3 to 5 days on each month, according to the length of his sentence, and the term for which he is imprisoned is materially diminished in this way if his conduct is uniformly good. This plan is liable to some serious objections. A better one is that of intermediate prisons, now adopted in Ireland. A regular scale has been adopted, and the prisoner who is sentenced for 10 years may, after serving 6 years in a "separate" prison, if his conduct has been good, be then transferred to an intermediate prison, where he is employed with others who have behaved well; and if his deportment is exemplary, at the end of a year and a half he receives a ticket of license, which permits him to be at large, but under the surveillance of the constabulary, at whose offices he is registered; if he behaves well he is unmolested, but if he falls into vicious habits he is remanded to the separate prison, to serve out the remainder of his term. This plan has already been tested in the case of nearly 2,000 prisoners in that country, and, it is asserted, with more satisfactory results, so far as the reformation of the prisoners is concerned than any other.—Within a few years past considerable attention has been bestowed upon the condition of discharged prisoners. Through the efforts of the late Isaac T. Hopper the New York prison association was organized for the relief of this class, and with a small income has accomplished a large amount of good. A separate association has opened a home for discharged female prisoners. In Boston a similar organization exists, and a periodical called "The Prisoner's Friend" is published by the Rev. Mr. Spear. In London an association called the discharged prisoner's aid society has been formed for the accomplishment of the same purpose.—See John Howard, "The State of the Prisons in England and Wales" (1777), "Account of the Prisons and Hospitals in Russia, Sweden, and Denmark" (1784), and other works; Bentham, "The Panopticon, a Plan for a New Prison" (1799); "State of the Prisons in England, Scotland, and Wales," &c. PRIVATEER, an armed private vessel which bears the commission of a state to cruise against the commerce of its enemy. When one sovereign has duly declared war against another, all the subjects of the former are enemies of all the subjects of the latter. From this principle of the law of nations follows the unquestionable corollary, that no citizen of one of the belligerent states can complain of the hostile acts of any citizen of the other. Therefore, as far as absolute international rights are concerned, it makes no difference whether a depredation or capture by a subject of the enemy has or has not been expressly sanctioned by his sovereign. The universal practice of nations, however, condemns all unauthorized hostilities; and a capture or other hostile act without the sanction of a competent sovereign power, although, strictly speaking, it would not be piracy, yet would be so much like it, or so irregular and odious, that it would unquestionably provoke the severest treatment at the hands of an enemy against those who engaged in it. Yet, though unauthorized capture of enemy property is no offence under the law of nations, it is an infraction of the public law of the captor's own state. For the universal rule is that, except in self-defence, only those subjects may take part in hostilities who are thereto expressly or constructively authorized by their sovereign. In him alone resides the power of making war.

In the exercise of it he may employ what means he pleases. He may limit himself to his own ships, or he may resort to those of other states. Of the former he may employ only his public vessels, or he may avail himself of the private vessels of his subjects by commissioning them to seize the merchant ships of the enemy. These commissioned private ships or privateers are in naval warfare much the same as the volunteer corps are in the land service. In both cases the commissions proceeding from the sovereign make those who bear them the instruments and servants of the state. On the sea it is the letters of marque which give that interest in the prize which is the inducement to engage in the service. For, primarily, all prizes vest in the state, and it is the commission alone which, under the municipal regulations of each state, defines the proportion of the captured property and the other rewards which shall fall to the privateersman. (See PRIZE.) To guard against the excesses and abuses which are incident to privateering, it has been subjected to various restrictions. Some states have regulated the composition of the crews, and have forbidden all cruising in the rivers or along the coasts within the sea line of the enemy. Generally commissions are granted on condition that the rights of neutrals shall be respected, and that belligerent rights shall in all cases be enforced according to the rules of war; that prizes shall be brought for adjudication before the proper tribunal; and that the whole conduct of the cruise shall be confined to the instructions of government. Bonds are taken for the due performance of these engagements, and owners and officers are subjected to penalties for the violation of them.—Privateering may be regarded in two aspects, or rather it may be said that there are two kinds of privateering, one of which is far more legitimate and defensible than the other. The former of these kinds is that in which the citizens of one of the states at war sail under their own flag against the enemy. They find employment in this way for the ships which during war must almost of necessity be withdrawn from trade; and they contribute very materially to the maritime strength of their state. In such a country as the United States, which from various motives maintains an inconsiderable navy compared with those of the great maritime powers of Europe, the assistance of the mercantile marine would be in case of war almost indispensable. In fact, making war vessels of merchantmen would be nothing else than the creation of an adequate naval fleet. This sort of privateering the United States has always defended and encouraged, though, as will be presently seen, it has professed itself willing to surrender on fair conditions even this manifest and just advantage. The other and more odious form of privateering is that in which a neutral accepts a commission from one of two belligerents. Here the legitimacy of the practice is not so clear, at least so far as affects the neutral. He can certainly have no patriotic motive in accep such a commission. Such a motive is probably even when the privateer sails the flag of his own country; but the country does really derive some benefi the service. In the case supposed, the is a sort of legalized pirate, and so indeed regarded by those conventions and trea which, in condemnation of this abuse of international laws of war, almost all na have entered into. The French *ordonnance la marine* expressly declared such practi be piracy. The treaties between France Holland in 1662, between the United S and France in 1789, of the United States England in 1794, with the Netherlands 1792, with Prussia in 1785 and 1799, and Spain in 1795, with Sweden in 1783 and all declared that if any citizen of either tracting power should take letters of marq carry on privateering against the other any power with whom the other was at he should be treated as a pirate. The practice of nations also accords with the of these express compacts. In the war Mexico, England and France forbade their jects to accept the privateering commis which were offered by that power. So in late Russian war, the neutral European st prohibited their subjects from taking par the war, either by accepting letters of mar or otherwise aiding the belligerents. Aus Denmark, and Sweden and Norway exc privateers from their ports. The foreign en ment acts of Great Britain and the United Sta are permanent statutes, which impose seve penalties on citizens or residents who recei commissions, equip privateers, or enlist men service in any foreign war. This species privateering seems to be well nigh repres Not so the other. For nearly a century the pediency of its suppression had been at intervals elaborately discussed; yet in all that period but little advance had been made tow the settlement of the question. In 1856 subject was revived at the congress which convened at Paris after the Russian war, and the states there represented made mutual engagements to surrender the practice of privateering. The United States still maintains its old position. As early as 1785 (to review briefly the doctrine and practice of our government upon this matter) the United States made an effort to abolish privateering. In that year, and while he was negotiating with Prussia the treaty which was afterward concluded, Dr. Franklin wrote: "The United States of America, though better situated than any European nation to make profit by privateering, are, so far as in them lies, endeavoring to abolish the practice, by offering in all their treaties with other powers an article engaging solemnly that in case of future war no privateer shall be commissioned on either side, and that unarmed merchant ships on both sides shall pursue their voyages unmolested." Dr. Franklin procured sertion of both these propositions in the y with Prussia. In the subsequent treaty 790 with that power, however, all provi- of this character were omitted. In 1792, y be mentioned in passing, the legislative ably of France proposed that nations should e by mutual conventions to abolish pri- ring and the seizure of private property on cean. The proposal met but little favor, these practices were perhaps never more sively carried on than during the wars h followed the French revolution. Again 24 the subject was revived, when, on our again, it was urged upon the attention of English government. The plenipotentia- Messrs. Huskisson and Stratford Canning, lined however to entertain the propositions or minister, Mr. Rush, and he reported to ernment that in his opinion Great Britain unwilling, under any circumstances, to ac- to the abolition of private war upon the n. But a radical change in the sentiments nglish publicists upon this question is in- ted, it would seem, by the language of Lord endon in 1854. In submitting to our am- dor, Mr. Buchanan, the declaration re- ting neutrals which France and England rward issued, the British minister advocat- the abandonment of privateering, and ex- ed his condemnation of the practice as one h was "inconsistent with modern civiliza- ." Mr. Buchanan replied, that under exist- circumstances it did not seem possible for United States to agree to a surrender of the tice, unless the naval powers of the world ld go one step further and consent to the ition of all war against private property n the ocean, as was already agreed upon as private property upon the land. In answer Mr. Buchanan's despatches, Mr. Secretary cy reminded the British government that United States laws go as far as and even ther than those of any other nation in pro- iting its subjects from entering into foreign ateer service; but he added that the coun- would not enter into any convention where- it would preclude itself from resorting to its chantmen in case of war. Finally the sub- sion to our government of the declaration ich was signed at Paris in 1856, by the plen- tentiaries of the chief states of Europe, led for a new consideration of the question. ide provisions affecting the rights of neu- ls, the convention contained an article which clared that privateering was abolished. The r points of the declaration were to be re- ded as an entirety; they were to be binding ly between those powers which assented to m; and the states that signed the conven- n undertook to invite the accession of those wers which were not represented at the con- ss. Most of the secondary states of Europe d America gave prompt adhesion to the ar- les of the declaration. The United States lined to do so. It objected to the privateering clause, and alleged the same grounds of objection which it has always urged. The answer of our government to the declaration was, through Mr. Marcy, that the United States would accept the whole of it "in case the clause abolishing privateering were amended by adding that the private property of the subject or citizen of a belligerent on the high seas should be exempted from seizure by public armed vessels of the other belligerent, except it be contraband of war."

PRIVET (*ligustrum vulgare*, Linn.), the ordinary name of a half evergreen shrub used for live hedges. The common privet belongs to the natural family *oleaceæ*, trees or bushes having simple, mostly entire leaves, perfect or polygamous flowers with calyx and corolla, and the fruit either a berry or a drupe. (See OLIVE.) The genus *ligustrum* is distinguished by its short, tubular, 4-toothed calyx, and funnel-shaped, 4-lobed corolla, the tube exceeding the calyx; the stamens are 2, inserted into the tube; the style very short, stigma obtuse, bifid; berry globose, 2-celled and 1-seeded; albumen somewhat hard; embryo inverted. The common privet, also called prim, occurs in pastures and fields in eastern New England and in New York. It is a hardy shrub with numerous branches, growing in clumps from strong, matted, yellow roots, and rising to the height of 6 to 8 feet. The leaves are small with very short petioles, opposite or crowded in tufts, lanceolate-acute at both ends, entire, pale green, and smooth on both sides. The flowers are borne upon short terminal panicles, the calyx short with 4 very blunt teeth, the corolla a short tube with 4 oblong, expanded pointed segments; the tube encloses 2 very short stamens with large sulphur-colored anthers, whose pollen is fragrant; the berry is of a polished black color and very conspicuous in winter. The foliage turns rusty and shrivels, falling off as the cold becomes severe; but when in full leaf and flower the shrub is pleasing to the eye.—The privet is raised from the seeds. The method generally considered the best is to gather the berries as soon as mature and place them in a heap to rot, sowing the seed in the spring; others advise that the berries themselves be sown at once. The usual mode of propagation in Europe is by cuttings, which root easily. The plants flourish especially in a strong, loamy, moist soil, but they will grow in almost any kind, and even under the shade and drip of deciduous trees. If intended for low trees, the side shoots should be rubbed off; otherwise they require very little pruning. When set out for live hedges in a good soil and sheltered situation, the foliage sometimes survives the winter. Scarcely any other shrub forms so beautiful a low hedge, and few are so exempt from disease or from the ravages of insects. The wood of the privet is hard and close-grained, and when of sufficient size is fit for turning in the lathe; it also makes a superior charcoal for the manufacture of gunpowder. The leaves and bark are bitter, and the smaller twigs clipped in June, dried and pulverized, are used in some parts of Europe for tanning leather. The young slender branches and shoots are employed like osiers for basket making and for tying packages. The berries afford a rose color which is used in tinting maps and prints; they are also eaten by several kinds of birds. A greenish oil fit for lamps or to make soap is extracted from them by pressure.—There are several varieties of the common privet, such as the white-berried, yellow-berried, green-berried, the narrow-leaved, and the variegated leaved; but the most desirable of all, especially for live hedges, is the Italian or evergreen. The spike-flowered privet (*L. spicatum*, Hamilton) is a native of the mountains of Nepaul, a shrub 6 or 8 feet high, with elliptical acute leaves, which are hairy on their lower surfaces; the flowers crowded, almost sessile, disposed in a thyrse, white, appearing in June and July. The wax tree (*L. lucidum*, Aiton), so called from excreting a waxy matter, is a small tree 10 to 20 feet high, with broad, ovate-oblong, acuminate leaves, shining on their upper surfaces, the flowers in thyrsoid panicles, white. It is a handsome object when trained to a single stem, and may be propagated by layers, cuttings, or by grafting upon the common privet. It is a native of China. Other species are known indigenous to Japan, China, and the East Indies.

PRIVY COUNCIL. See Council.

PRIZE, any property captured at sea in virtue of the rights of war. A difference exists in practice between war on land and on the sea in respect to private property. On land private property, with some exceptions, is respected by all civilized nations; but at sea all the property of every citizen of a belligerent country is liable to capture.—The general rights of a belligerent are to make captures by his public armed vessels of war, to grant commissions to private persons for the same object, and to establish tribunals of prize for the purpose of examining into all maritime captures, and of judicially deciding upon their validity. By the declaration of war all the citizens of the belligerent countries respectively become enemies, and the citizens of one country may seize any property of the other that they may meet with at sea. Property however so seized belongs to the sovereign of the country, and not to the captors, except it is given to them as an act of grace on the part of their sovereign. For this reason, and also that the government of the country may have the power to limit and control the operations of the war, commissions are usually granted by the government to private persons authorizing them to make such captures, and after adjudication by a competent tribunal they are entitled to the proceeds of the prizes thus taken. (See Privateer.) It is obviously necessary that when a capture has been made there should be some tribunal with authority to pass upon the validity of the capture, and to pronounce a decree of condemnation or acquittal. It is therefore the right and duty of the government of a country, on the declaration of war, to establish tribunals of prize; and is then responsible to all foreign nations for the correctness of the decisions therein made. So far as the property in question is concerned, the sentence of the prize court is conclusive upon all the world. If the sentence is of condemnation, the title of the former owner of the property is divested, and all nations are bound to respect the new title acquired under it. To give the decision of the court this effect, however, it must appear conclusively that the court had jurisdiction over the property in question. The court must be established in the country of the captor, or in that of his ally in the war, but it is not necessary that the prize should be brought within a port of either of these countries. It is the practice of Great Britain and of the United States to adjudicate upon captures which have been carried into a neutral port.—The next question to be considered is: Who are enemies, and what property is liable to capture? For this purpose not only the native-born citizens of the belligerent are considered as enemies, but all persons who have their domicile in the hostile country, and the citizens of a country which is under the permanent or temporary dominion of the enemies of another country, are considered as citizens of the latter, and all trade with them is illegal, unless the government chooses to recognize the country as neutral, in which case courts of justice are bound by such recognition. It is very doubtful whether a citizen of one country can expatriate himself on the breaking out of war, in order to acquire neutral rights and privileges; but it is certain that if he removes in order to mask his mercantile projects under a neutral flag, such an act is fraudulent and of no avail. But if he has removed during peace, and acquired a domicile in a foreign country, he may engage in trade with a country which is at peace with his adopted country, although at war with that of his nativity. The question of the domicile of a person is generally to be determined by his intention. Thus if he goes to a foreign country for a temporary purpose, with the intention of returning after accomplishing his object, he would not acquire a domicile there. If, however, he should remain there a long time, this would be evidence, though not conclusive, of his intention to make that country his domicile. If it sufficiently appear that the intention in removing was to make a permanent settlement, or for an indefinite time, the right of domicile is acquired by a residence even of a few days; and a neutral or subject found residing within a foreign country is presumed to be there *animo manendi*, and if a state of war should bring his national character into question, it lies upon him to explain the circumstances of his residence. If a person becomes a citizen of another country by naturalization or residence, his native nationality easily reverts; but a mere visit to his original country

d not reintegrate him as a subject of that
ry, if such visit was intended to be of
t duration only. A citizen of one country
ing and doing business in another, resumes
tive character if, on war breaking out, he
himself *in itinere* to return to the country
birth or adoption; but the mere inten-
without some overt act is not sufficient.
an may have a neutral residence, and yet
property may acquire a hostile character.
he may be a merchant in more countries
one, and may thus acquire at last a *quasi*
icile beside that of his birth and parentage;
this would be respected by the law, pro-
d there was no indication of fraudulent in-
ion, that is, of giving himself two national
acters, between which he could choose
time to time, as suited the exigencies of
moment. The property of a house of
e in an enemy's country is liable to con-
nation, whatever be the domicile of the
ners who constitute the house. If some of
partners have a neutral residence, their sep-
e property will not be affected by the fact
eir being connected with a house of trade
a hostile country. And when a shipment is
de by the house to a partner in a neutral
ntry, or by a partner in a hostile country to
ouse in a neutral country, it depends upon
question to whose account and risk the
ds are shipped, whether they are liable to
condemned as prize. Commercial factories
a foreign country, which are free from the
trol of the government of that country, are
sidered as belonging to the country by
ch they are established, and the nationality
persons engaged therein is determined ac-
lingly. But this exception does not apply
ere the government of the country has the
trol, although peculiar privileges are grant-
to the subjects of a particular nation. A
ign minister does not lose his domicile in
own country by residing in the foreign one
which he is accredited; but if he engages in
de there, he is, in respect to such trade, con-
red as a citizen of the country where it is
ried on. The domicile of a mariner is the
ntry of his birth; but if he engages in a ship
trade which is hostile to a particular country,
is in respect to that country considered as
enemy.—It sometimes occurs that circum-
nces will not permit property captured at sea
be sent into port. The captor in such a case
y destroy it, or allow the master or owner
ransom it. Such a contract is valid by the
v of nations, but is prohibited in England by
tute. By the ransom bill the vessel is pro-
d from subsequent capture until she reaches
own country, or the country specified in
bill, provided there be no deviation from
course of the voyage. Generally some of
officers and crew are retained as hostages,
d if they die, or the vessel is lost by a peril
the sea before her arrival in port, unless it
otherwise stipulated in the bill, the ransom
nevertheless due; for the captors do not insure either the safe arrival of the vessel or the lives of the hostages. If the vessel deviates and is afterward captured and condemned, it has been questioned whether the debtors of the ransom are discharged from their contract. According to Valin it is the constant practice in France to consider the debtors as discharged, and the price of the ransom is deducted from the proceeds of the prize and given to the first captor, and the residue given to the second. If the captor himself should after the seizure be taken by an enemy's cruiser, together with the ransom bill, the ransom becomes part of the lawful conquest of the enemy, and the debtors of the ransom are consequently discharged from the contract under the ransom bill.—The right which a captor acquires by the seizure is an inchoate right merely, and is subject to be divested before condemnation. If there is a recapture, escape, or voluntary discharge of the property, a court of prize cannot proceed to adjudication. By the Roman law of *jus postliminii*, persons or things taken by the enemy were restored to their former state upon coming again into possession of the nation to which they had belonged. Formerly, as between the belligerents, the title to property captured passed after it had been in the possession of the captors 24 hours; and if after that time it was recaptured by third persons, they became the absolute owners of it. Now, however, the property of the original owners is not divested until condemnation, and the recaptors are merely entitled to salvage, the amount of which is in the United States fixed by statute for most cases, and when not so fixed is determined by the general principles of law. Salvage has been allowed where, although the original capture was illegal, the acts of the government showed that the law of nations would have been violated and the vessel condemned if it had been taken in. There is some conflict of authority whether the crew of a vessel who recapture it before condemnation are entitled to salvage. It would seem that in the United States they are not, because it is considered to be the duty of the crew to do all that they can to save the vessel until she is condemned. If a treaty of peace makes no particular provisions relative to captured property, it remains in the same condition in which the treaty finds it. In England, as between English subjects, the right of postliminy subsists to the end of the war, and foreign nations are treated with the same liberality which they accord in similar circumstances to England. The property of a subject or an ally engaged in commerce with the enemy is liable to capture; and it makes no difference whether the trade be direct or indirect. The law of nations permits vessels to sail and chase under false colors, but not to fire a gun or capture under them.—It has become an established principle of the law of nations, that a nation which takes no part in a war shall have the same rights which it has in time of peace, except so far as the ex-

ercise of these rights would materially interfere with the permanent rights of the belligerents. Within her own territory, which for this and other purposes extends a marine league from the shore, a neutral nation is supreme. No belligerent has a right to make a capture in her waters, or to arm or equip his ships of war in her ports, and if either of these things is done the neutral is bound to redress the injury. A ship has no right to station itself in a neutral port and send out boats to make hostile seizures. It has been thought by some jurists that if a vessel is pursued and goes into a neutral port, it may be pursued *dum fervet opus*, and captured; but the better opinion is that this is a clear violation of the neutral territory. The neutral nation may allow certain privileges to one of the belligerents, but only such as she is willing to allow to the other. She cannot lend money to one belligerent, but if she is under a previous stipulation, made in time of peace, to furnish a given number of ships or troops to one of the belligerents, the contract may be complied with. But it is said that she is not bound to do this if her ally was the aggressor. If a prize is brought into a neutral port, the neutral government may exercise jurisdiction so far as to restore the property of its own subjects which has been illegally captured. And it has been held in the United States that foreign ships, which offend against the laws of that country within its jurisdiction, may be pursued and seized upon the ocean, and brought back for adjudication. In 1793 the government of the United States established rules of neutrality which it required foreign belligerent powers to observe in their intercourse with this country. Among others was one which provided that if an armed vessel of one nation should depart from our jurisdiction, no armed vessel being within the same and belonging to an adverse belligerent power should depart until 24 hours after the former. It is now a universally admitted principle of the law of nations that a belligerent has a right in time of war to visit and search all vessels on the ocean, in order to determine whether they or their cargoes are hostile or neutral. This right gives also as a necessary incident the right to seize and send in the vessel for adjudication, whenever its real character, or that of its cargo, is justly open to suspicion. The neutral must submit, and if her crew rise and endeavor to recapture the vessel, it is a hostile act, which subjects the vessel and cargo to condemnation. Neutral goods may be carried in a belligerent vessel even if the latter is armed, according to the law in the United States; and a neutral ship is not subject to seizure if she has belligerent goods on board. Attempts have been made at different times to engraft on the law of nations the principle that free ships make free goods, but the law remains unchanged, except as it has been modified by treaties between particular nations. The question whether a country, which during peace confines the trade of its colonies to its own subjects, can during war open such trade to a neutral, has been much discussed. In England it has been held that it cannot; but this rule has been repudiated by the government of the United States. Neutrals are not permitted to carry goods which are contraband of war, or to enter a blockaded port. (See BLOCKADE, and CONTRABAND.) Breach of blockade forfeits the vessel, and in some cases the cargo; but according to the modern practice, the carrying of contraband goods only forfeits the goods, and the owner of the vessel loses merely his freight and expenses, unless the same person owns both ship and cargo, or some fraud appears in the transaction, in which cases both ship and cargo are forfeited. If an enemy's cargo is captured in a neutral vessel, the vessel has a claim on the captors for freight. But this rule is limited by the reason of it, and if the cargo be contraband, or the voyage be *quasi* contraband, then the neutral vessel loses its freight. The rule that freight is not earned unless the goods are carried to their destination, applies to capture. But if the captor takes the goods where they should have been carried, and even if he does this substantially though not precisely, as by bringing goods to Boston which were destined to New York, freight is due.—All seizures at sea are made at the peril of the captors. If, on being sent in, the vessel and cargo are acquitted, the captors are responsible for all damages and costs, unless the capture was made with probable cause. What is probable cause is a question of some difficulty, and depends very much upon the facts of each particular case. In general, if the papers appeared false or colorable, or were suppressed, mutilated, or spoliated; if the voyage were to or from a blockaded port; or if other circumstances of a like nature occurred, the captors would be justified in sending the vessel in for adjudication. After the vessel is captured, the captors are responsible for any loss which may occur by the negligence, fault, or misconduct of the prize officers and crew; but they are not responsible if a loss occurs from accident, stress of weather, recapture, &c.—While a ship is forfeited by the master disguising belligerent property on board as neutral, without the authority, assent, or knowledge of the owner, this act does not operate as a breach of neutrality as to the goods on board which are actually neutral and proved to be so by proper documents, and belong to another owner than him who has forfeited the goods. If neutral interests or property are undistinguishably mixed up with belligerent interests or property, they become liable themselves to all the incidents and effects of a belligerent character. A resistance to search when rightfully demanded, an attempt at rescue, and seeking belligerent protection or receiving it, are all breaches of the duty of a neutral; but it is said in qualification of this rule, that if any of these or similar things are done because a belligerent renders them necessary by his own illegal conduct, they are justifiable. Some question has arisen as to what is a rescue. It is the duty of the captors to put on board persons competent to navigate the vessel into port for adjudication, and her own master and crew are not bound to do this. If the vessel is given up to them, and they pursue their original course against the wish of the captors, this is not a rescue. But if the neutral crew undertake and promise to navigate the vessel to the desired port for adjudication, and the vessel is given up to them for this purpose, and they violate their promise and take the vessel into their own hands for their own purposes, this is an unlawful rescue. Generally a cargo is considered as liable to condemnation, if any act has been committed by the master which subjects the ship to condemnation. But the cargo is not liable to condemnation if it is the property of a person other than the owner of the ship, and its owner was not cognizant of the intended violation. If, however, the owner of the cargo gave the master discretionary power, he is liable for his acts; or if the cargo was loaded after notification of a blockade, the parties having full knowledge of the fact. Resistance to the right of search, the rescue or recapture of the ship by the master and crew, and the fraudulent suppression or spoliation of papers, affect the owner of the cargo as well as the owner of the ship.—By a statute in the United States, it is the duty of the master to carefully preserve all the papers and writings found on board a prize, and transmit the whole of the originals unmutilated to the judge of the district to which the prize is ordered to proceed, and transmit to the navy department, and to the agent appointed to pay the prize money, complete lists of the officers and men entitled to a share of the capture, inserting therein the quality of every person rating. The prize master is also required to make an affidavit that the papers are delivered up as taken, without fraud, addition, subduction, or embezzlement. The master of the captured vessel, the principal officers, and some of the crew should be brought in, and these persons are examined on the standing interrogatories prepared by the court for that purpose. At this examination no counsel are permitted to be present. Only the papers and documents delivered up to the captors are admissible; and if the captors conceal any, they cannot afterward be put in. The case is determined on this evidence and the documents of the prize; but, if it is necessary, the court will require further proof from either party alone or from both. Oral testimony is never admitted. Although the evidence of the captors is not allowed in the first instance, yet original evidence taken on the standing interrogatories in other prize causes is admissible. In cases of joint or collusive capture, the usual simplicity of prize proceedings is necessarily departed from; and where there is the least doubt, other evidence than that arising from the captured vessel, or invoked from other prize causes, may be resorted to. The principal grounds for condemning a ship as prize, where the question of nationality is in dispute, are: 1, the entire want of the necessary papers; 2, their destruction; 3, their material alteration or falsification; 4, the time when the papers were made out, as whether before or after the war, is often material; 5, next in importance is the conduct of the master and officers; 6, their prevarication or evident falsehood in the preliminary proof; 7, their refusal or inability to give a good account of the ship and cargo; 8, the domicile of the master and officers. The spoliation of papers, by which is meant, not merely their total destruction, but such falsification as makes them useless or worse as evidence, is a circumstance of grave suspicion, but is open to explanation; and if the captured in the first instance fairly and satisfactorily explains it, he is deprived of no right to which he is otherwise entitled. Possession by an enemy is presumptive proof, though not conclusive, of hostile character. Ships are presumed to belong to the country under whose flag they sail; and it has been thought that this presumption should be conclusive as against the person using the flag. In joint captures all public ships of war in sight are presumed to assist, and therefore they are entitled to share in the proceeds; and this presumption extends to all the ships of a squadron united by authority for a specific purpose, as for a blockade for example, although not actually in sight; but it does not apply to privateers, because they are not obliged to capture all vessels they meet, as are vessels of war. Revenue cutters, as they are generally employed to protect the revenue, and have no special injunction to capture enemy's vessels, come under the same rule as privateers in this respect. Every ship is expected to have on board the necessary papers to establish her nationality; and these are the papers which the law of her own country require as evidence of that character. The same rule applies to cargoes. The burden of proof is on the claimant to prove a neutral proprietary interest. Property found on board an enemy's ship is presumed in the absence of proof to the contrary to be enemy's property; and a person claiming under a title by capture must show a valid sentence of condemnation. The sale of a ship or cargo under a decree of admiralty, founded on condemnation as prize, is valid and binding upon all courts and parties, unless it is shown to be vitiated by fraud.

PRIZE MONEY. The distribution of prize money, or of the proceeds of the sale of ships or goods adjudged by courts of admiralty to be good prize, is carefully regulated by statutes of the United States. The provisions are very minute; but substantially they are as follows. 1. When the captures are made by public armed ships, if the captured ship be of equal or greater force than the ship making the capture, the proceeds belong wholly to the captors; otherwise they are equally divided between the United States and the captors. The commanding officers of fleets, squadrons, or single ships take 3 twentieths, the whole of which goes to the commander of a single ship acting independently; but if he is under the command of an officer of a fleet or squadron, that officer has one twentieth, and the commander of the ship the other two. Sea lieutenants, captains of marines, and sailing masters take 2 twentieths; chaplains, lieutenants of marines, surgeons, pursers, boatswains, gunners, carpenters, and master's mates, 2 twentieths; midshipmen, surgeon's mates, captain's clerks, schoolmasters, boatswain's mates, gunner's mates, carpenter's mates, ship's stewards, sailmakers, masters at arms, armorers, cockswains, and coopers, 3½ twentieths; gunner's yeomen, boatswain's yeomen, quartermasters, quarter gunners, sailmaker's mates, sergeants and corporals of marines, drummers, fifers, and extra petty officers, 2½ twentieths; seamen, ordinary seamen, marines, and all other persons doing duty on board, 7 twentieths. One or more public ships in sight of a capture share equally in the prize or prizes. A bounty is paid by the United States of $20 for each person on board of any ship of the enemy at the beginning of an engagement, which is sunk or destroyed by a public armed vessel of equal or inferior force; and this bounty is divided as prize money. 2. If the ships or goods are captured by private armed ships commissioned by government, the prize property, within 60 days after condemnation, shall be sold by the marshal of the district in the manner and on the terms designated by the owners of the privateer, and the proceeds divided between the owners, the officers, and crew, according to their articles of agreement; and if there are no articles of agreement, one half goes to the owners, and one half to the officers and crew. Usually, if not always, the shipping articles of a privateer or letter of marque determine the proportions in which the proceeds are to be divided.

PROBATE, in law, the proof, before the competent authority, that an instrument offered, purporting to be the last will and testament of a person deceased, is indeed his lawful act. Until the act 20 and 21 Victoria, c. 77 (1857), amended the law relating to probates and letters of administration in England, the custody of the estates of all deceased persons vested there primarily in the ordinaries or bishops of dioceses, subject only to the exceptional rights of the crown or of lords in respect to certain manors. The new act of 1857 abolished the ancient ecclesiastical jurisdiction, and conferred full and exclusive authority over all testamentary causes upon the queen, to be exercised in her name in a court to be called the court of probate. Ecclesiastical courts never existed indeed in the United States; but from the very settlement of the country the office and functions of the English ordinaries have been exercised here by similar officers under various titles, and generally with larger powers than those functionaries possessed. In New York probate is granted by the surrogate; in South Carolina by the ordinary; in Pennsylvania by the register of wills, who is also a judge, and his probate a judicial act. In some states the county courts, and in others the orphans' courts, grant letters of probate; and in most probate is granted by a judge of probate. These several judicatures concern themselves only with the *factum* of a will. They declare whether or not a valid will exists, and no executor, or administrator with the will annexed, can assert his rights in any court without showing his letters testamentary; that is to say, the legal evidence that the will under which he claims to act has been approved and established in the court of probate. The construction of the will, or the operation and effect of its particular provisions, rests with the courts of law; and where the original court of probate takes any jurisdiction of these questions, an appeal lies from it to the higher courts of law or equity. In England the rule has been that probate was necessary of such instruments only as were testamentary and regarded personal property. If they affected lands alone they needed not to be proved in the spiritual courts. In this country the rule is different. In many of the states, certainly in Massachusetts, Vermont, New Hampshire, Maryland, Michigan, and Ohio, it is expressly provided by statute that no will shall be effectual to pass either real or personal estate unless it shall have been duly proved and allowed in the probate court. So in New York, all wills in which an executor is named, whether they relate to real or personal property, must be formally proved. And generally, whenever power is conferred in general terms on probate courts to take probate of wills, it is presumed in this country that their jurisdiction includes wills as well of realty as of personalty; and their decrees in both these respects are regarded as conclusive. So long then as the probate remains unreversed on appeal, the due execution of the will, the sanity or capacity of the testator, and the attestation of the witnesses, cannot be called in question in the courts of common law. The same rule is in some states observed in respect to wills once admitted to probate, though they were made and executed in other states according to forms not sufficient where they were approved. In some states the probate of wills of lands is *prima facie* evidence, but not conclusive, of the due execution of these instruments; in others the probate becomes conclusive in these respects after the lapse of a certain number of years—2 in Ohio, 5 in Mississippi, and 7 in Virginia. In New York it has been held that the sentence of the surrogate, affirming a testator's competency to make a will of personal property, is not conclusive as to a devise of real estate contained in the same will upon the parties to a subsequent suit. It is matter of common law that the competent authority may, either *ex officio* or at the instance of a party in interest, order the executor, or any other who has the custody of an alleged will, to exhibit it for probate. This power is incident to the general jurisdiction of probate and of granting administration. In this country statutes in many states define this authority more precisely, and prescribe the method of exercising it. Refusal to comply with the order of the court in such a case is punishable by imprisonment. In New York the production of the will is commanded by subpœna. Sometimes the executor is required to offer the will for probate within a certain period after the testator's death, and his default is punished with a penalty. In Massachusetts any one may insist on the proof of a will who has a right to offer it in evidence or to make title under it; and it has been held accordingly that the creditor of a devisee has this right for the purpose of procuring satisfaction of his debt.—In most of the states the procedure of the court upon probate is fixed by the legislature, and the common law distinction between probate in common form and in solemn form has in great measure disappeared. In North Carolina, Georgia, Tennessee, and probably elsewhere, the distinction however is still observed. A will is said to be proved in common form, when the executor presents it to the court, and, without summoning any of the parties interested, calls one or more witnesses to prove its execution. The objection to this mode of proof was, at common law, that at any time within 30 years the executor might be called upon by any party in interest to make proof in solemn form. This mode is not in common use in the United States, and even when it is used the time within which probate may be contested is much reduced by statute. Thus, in New Hampshire the revision must be made within a year; in Mississippi the validity of the will may be disputed within 5 years; in Virginia 7 years is allowed for the same purpose. Proof is made in solemn form, or by form of law or *per testes*, when all persons whose interests are to be affected by the will have been duly notified to be present, and have had opportunity to be heard in the premises. This is now the usual mode of proof in the United States, and after the will is approved in this way it is for ever binding. The method of proof, however, like many other points of probate practice, is often regulated by particular statute provisions. The testimony which the judge calls for at the hearing relates to the *factum* of the will, as the phrase is. The question being whether the instrument is a will or not, it is of the first importance to inquire into the capacity of the testator, and whether he did in fact execute the alleged will as it purports to have been executed. It is to furnish evidence on both these points that disinterested persons are invited to witness the execution of a will. These attesting witnesses are then most essential parties in a question of probate. Generally all of them must be summoned if they are living within the process of the court; but if from death, or absence from the country, or from incompetency arising since the attestation, any witness cannot be produced, the will may be proved by the others and by proof of the handwriting of the party who fails. If all are dead, or out of the court's jurisdiction, the handwriting of all must be proved; and probably in such a case the handwriting of the testator also. The attestation clause is generally framed with a regard to the requirements which the statutes of the state where it is made render essential to the valid execution of a will. If the evidence of the witnesses shows plainly that these requirements were not followed, the presumption of a valid execution furnished by the recital of them is overset; but if the subscribing witnesses have lost all recollection of the particulars of the transaction, the formal execution will generally be presumed and the will admitted to probate. Failure of memory on the part of one of the witnesses may often be supplied by the evidence of another or of the rest of them. In affixing his name, an attesting witness is regarded as certifying the capacity of the testator. His subsequent attempt to impeach the instrument by declaring that the testator did not execute the will with an intelligent and disposing mind is justly open to suspicion. Evidence of this character is not to be entirely rejected, though it avails little without the support of other testimony. When 30 years have passed since the death of the testator, a will is said to prove itself; the subscribing witnesses being presumed dead, the bare production of the instrument suffices. The will must however have come from a custody which forbids question of its genuineness, and be in other respects free from suspicion, or the genuineness must in some way be proved. Though it is a general rule, which applies as well to wills as other writings, that evidence *ab extra* is inadmissible to control them, yet when any such ambiguity is patent upon the face of the instrument as tends to call in question the *factum* of the will, there must be of necessity a resort to extrinsic evidence. Examples of such ambiguity are those cases where it is doubtful whether the writing was subscribed merely by way of authenticating what in fact were memoranda of a will to be made, or whether it was intended by the testator as indeed a final will; whether he intended to embody a particular clause in his will, or whether it was introduced without his knowledge; whether the residuary clause was or was not intentionally omitted; and the like matters, which go to the fact, not to the effect of the instrument. If the testator were blind or illiterate, the court will require proof that the will was *properly* read to him, and that he executed it intelligently. Interest under a will, however slight, incapacitates one from giving evidence in support of it, where the old rule of the common law remains in force; but this incapacity may be removed by the witness renouncing or releasing his interest.—Wills alleged to have been lost, destroyed, or mislaid, may be admitted to probate on proof of these facts, and on clear and satisfactory evidence of their contents. No parol evidence of the contents of a will alleged to be lost will be received, until it appears conclusively that diligent search has been made for the necessary document in those places where it would most naturally be found.

PROBUS, Marcus Aurelius, a Roman emperor, born in Sirmium, Pannonia, about A. D. 232, assassinated there in 282. While still very young he gained the favor of the emperor Valerian, who raised him to the rank of tribune long before the regular age. He commanded successively the 3d and 10th legions, and served in turn in Africa and Pontus, on the Rhine, the Danube, the Euphrates, and the Nile. Under Aurelian he reconquered Egypt, which had fallen into the hands of Zenobia; and by the emperor Tacitus he was made commander-in-chief of the eastern provinces with 5 times the usual salary, the promise of the consulship, and the hope of a triumph. Upon the death of the emperor in 276 the armies of the East forced him to assume the imperial purple, and the downfall of his rival Florianus soon left him at the head of the Roman world. He first turned his attention to Gaul, where he recovered 70 flourishing towns from the Germans, destroyed 400,000 of the invaders, and drove the remainder across the Rhine. He penetrated into Germany, exacted from the inhabitants a heavy tribute of grain, cattle, and horses, and a restitution of the property carried away from the Roman provinces, and obliged them to supply the Roman army with 16,000 recruits. He also built a stone wall stretching from the neighborhood of Neustadt and Ratisbon on the Danube as far as Wimpfen on the Neckar, and thence to the Rhine, a distance of nearly 200 m. He secured the frontier of Rhætia, crushed the power of the Sarmatians, admitted the Goths to an alliance, and took several castles from the Isaurians. The rebellion of Saturninus, the commander of the eastern army, and the revolt of Bonosus and Proculus in the West, were speedily suppressed. Peace now prevailed throughout the empire, and Probus returned to Rome and celebrated a triumph. In order to maintain the discipline of his troops, he constantly employed them in active labor, and the hills of Gaul and Pannonia by their toil were enriched with vineyards. Finally an unguarded remark, that by the establishment of universal peace he should render a standing army unnecessary, proved fatal to him. While his soldiers were draining the marshes of Sirmium a mutiny broke out, and Probus fled to a high tower; but the troops forced his retreat, and put him to death. He is regarded as one of the best as well as ablest of the Roman emperors. He was succeeded by Carus.

PROCESS, in law, a term which, in a large sense, signifies the whole proceedings in any action, civil or criminal, real or personal, from the beginning to the end. In a narrower and more technical sense, the term is applied to different stages of the procedure; as is seen in the terms original process, which includes those precepts or writs by which one is called into court; final process, or the forms of procedure by which judgment is carried into execution; and mesne process, which covers the proceedings between the other two, and embraces all proceedings properly so called, as writs for compelling the attendance of jurors or witnesses, and for other collateral purposes. Mesne and final process are sometimes collectively described by the term judicial process, because proceedings in these stages of an action were authorized immediately by the court and issued under the hands and seals of the presiding judges. Original process, on the other hand, was so called because it was founded on the original writ, which, issuing out of chancery and bearing the *teste* of the sovereign, conferred jurisdiction on the court to which it was addressed, and founded its authority over the matter in controversy. In the strict technical sense, process is the means employed for bringing the defendant into court to answer to the action. The first step therefore in the ancient procedure was to give the defendant notice of the issue and pendency of the original writ. This notice was given ordinarily by summons, which was a warning to the party to appear at the return of the writ, and was served upon him by the sheriff or some of his messengers. If the defendant disregarded this monition, the next step was a writ of attachment, bidding the sheriff to take certain of his goods to be forfeited if he failed to appear, or to take the pledges of certain sureties of the defendant, who should be amerced in case of his non-appearance. If the sheriff made return that the defendant had no goods whereby he could be attached, or if after attachment he failed to appear, the court issued a writ of *capias* commanding the sheriff to take the defendant's body. This writ and all others subsequent to it were called judicial, because, as we have already seen, they proceeded immediately from the court, and not from chancery. The proceedings before *capias* became in time merely formal, and it was usual to sue this out in the first instance upon a supposed return of the sheriff.—The old system of process had become very abstruse, complicated, and inconvenient. Its evils were first brought formally to the public attention in England by the common law commissioners in 1828. The uniformity of process act, which followed soon after, abolished all other modes of original process, and supplied their place with five new rits. This statute was confined to personal tions. Real actions were provided for by atute 3 and 4 William IV., which destroyed l the old real writs but three, namely, dower, are *impedit*, and ejectment. Process was ill further simplified by subsequent acts, and as brought to its present position by the common law procedure act of 1852. All personal tions in the superior courts of law must now commenced in England by writ of summons. n some cases, indeed, arrest is still possible, d then *capias* may issue; but this writ can t now begin the action, as it might formerly ave done.—In some of the United States legis tion has been addressed lately to the simplifi ation of the forms of procedure. The New ork code abolished all the old forms of ac ons, took away all distinction between legal d equitable remedies, and established a uni rm course of proceeding in all cases and suits. ll civil actions in courts of record (and by a vil action the code means every action that not a criminal prosecution) are commenced y a service of summons, which requires the efendant to answer the complaint preferred gainst him by the plaintiff. In Massachusetts d other states process has been reformed by provements of a similar character, varying owever in their details.—In the criminal law ocess applies in an extensive sense to all ose instruments which are issued by compe nt authority for the purpose of bringing a rty into court, or of executing the judgment f the law upon him. The term thus includes mmonses, warrants, capiases, attachments, ittimuses, subpœnas, and all other writs which re employed in criminal cases. The state con itutions provide that all criminal process shall e in the name of the sovereign power, and is is expressed in different cases by the terms e state, the people, or the commonwealth.

PROCLUS, a Greek philosopher of the Neo-Platonic school, born in Constantinople, Feb. 8, A. D. 412, died in Athens, April 17, 485. The earlier years of his life were spent at Xanthus in Lycia, whence he went to Alexandria for the purpose of continuing his education, remained there several years studying under the most eminent teachers; and before he was 25 years old removed to Athens. At the age f 28 he had written several treatises, one of which was his commentary on the "Timæus" of Plato. Upon the death of Syrianus he succeeded that philosopher in the school at Athens, and from this circumstance he is sometimes called Diadochus (*i. e.*, the successor). Once he was obliged to leave that city, perhaps on ccount of having violated the laws of the Christian emperors; but after spending a year n the East he returned, and passed the remainder of his life at Athens. He adopted the scetic system which became common in the ater Neo-Platonic school, abstained almost en rely from the use of animal food, refused to arry, and observed numerous fasts and vigils. He worshipped the sun and moon, the spirits of heroes and philosophers, and even the spirits of the whole human race, and celebrated all important religious festivals, no matter of what nation. "His life," says Gibbon, "with that of his scholar Isidore, composed by two of their most learned disciples, exhibits a deplorable picture of the second childhood of human reason." In addition to his various religious exercises, he delivered 5 lectures a day. His extant works consist chiefly of commentaries, principally upon Plato. One of his original works is entitled "Twenty-two Arguments against the Christians," in which he endeavored to maintain the eternity of the universe. As a writer he is usually regarded as one of the clearest of his school, but as a philosopher his reputation has never stood high. Cousin, however, considers that all the philosophic rays which ever emanated from the great thinkers of Greece, Orpheus, Pythagoras, Plato, Aristotle, Zeno, Plotinus, and others, were concentrated in and remitted by Proclus. He was also distinguished as a mathematician and grammarian. There is no complete edition of his extant productions, but an edition by Cousin (6 vols. 8vo., Paris, 1820-'27) is most nearly so. Translations of several of his works have been made into English by Thomas Taylor.

PROCONSUL, a Roman magistrate who acted for the consul, with consular power, generally in the government of a province. He was almost always one who had previously been consul. The first proconsul was Q. Publilius Philo, who in 327 B. C. was at the head of the army in the second Samnite war when his consular year closed, and was then continued in the function beyond his time because his recall would have destroyed the advantages already gained. The proconsular dignity was always afterward conferred in similar cases.

PROCOPIUS, a Byzantine historian, born in Cæsarea, Palestine, about the beginning of the 6th century, died about A. D. 565. Removing to Constantinople when still young, he obtained there so much reputation as an advocate and professor of eloquence, that in 527 he was chosen secretary by Belisarius, and accompanied that commander in his wars against the Persians, against the Vandals in Africa, and against the Goths in Italy. During the last mentioned war he had charge of the commissariat department, and was at the head of the fleet. Returning with Belisarius to Constantinople about 542, he received from the emperor Justinian the title of *illustris* and the position of senator, and in 562 was made prefect of the city. The most important work of Procopius is his elegant and interesting "History" of his own times in 8 books, beginning with the war against the Persians, relating the wars against the Vandals and Goths and the history of the Gothic kingdom in Italy, and ending at the commencement of the year 553. The work has been translated into English by Sir Henry Holcroft (fol., London, 1653). Another work, entitled *Anecdota*, consists of a collection of anecdotes portraying the morals of the Byzantine court, and reflecting severely upon the prominent men of the time. The authorship of this has been questioned, but there is little doubt that it was written by Procopius. An English translation of it was published anonymously under the title of "The Secret History of the Court of the Emperor Justinian" (London, 1674). The best edition of Procopius's collected works is by Dindorf (3 vols., Bonn, 1833–'8).

PROCRUSTES (Gr., the stretcher), the surname of Polypemon or Damastes, a legendary robber of Attica, who had an iron bed upon which he placed all the travellers who fell into his hands; if they were longer than the bed, he cut enough from their limbs to make them fit; if they were shorter, he stretched them. He was slain by Theseus on Mt. Cephissus.

PROCTER, Bryan Waller, an English poet, better known by his anagrammatic pseudonyme of Barry Cornwall, born in London about 1790. He was educated at Harrow, where Byron was his schoolfellow, and, after passing some time in the office of a solicitor in Wiltshire, removed to London, and in 1831 was called to the bar from Gray's Inn. He has since that time steadily practised his profession, and for a number of years has held the office of commissioner of lunacy. His literary career commenced in 1819 with the publication of a volume entitled "Dramatic Scenes and other Poems," written, he said, "to try the effect of a more natural style than that which had for a long time prevailed in our dramatic literature." His remaining works are: "Marcian Colonna, an Italian Tale; with three Dramatic Scenes, and other Poems" (1820); "A Sicilian Story, with Diego de Mantilla and other Poems" (1820); "Mirandola, a Tragedy" (1821); "The Flood of Thessaly and other Poems;" "Poetical Works" (3 vols., 1822); "Effigies Poeticæ" (1824); "English Songs and other Small Poems" (1832); and "Essays and Tales in Prose" (1851). He is also the author of a life of Edmund Kean, and of a memoir of Shakespeare and an essay on his genius. His "Mirandola" was produced with considerable success at Covent Garden, and by many his dramatic pieces, founded on the style of the Elizabethan writers, are considered his highest efforts. He is however better known by his songs, some of which are singularly well adapted to music, and are equally refined in sentiment and diction. All his publications have appeared under his assumed name of Barry Cornwall.—Adelaide Anne, daughter of the preceding, has published "Legends and Lyrics, a Book of Verse" (1858; 5th ed., 1860), and "A Second Volume of Legends and Lyrics" (1861), containing poetry which, "without imitation, has much of the paternal grace and manner."

PROCTOR (Lat. *procurator*, agent), in a general sense, one who is commissioned to manage the business of another. In a particular sense, a proctor is one who is commissioned to transact the business of his principal in the ecclesiastical or admiralty courts. He discharges functions similar to those of attorneys and solicitors in other courts. In England, the proctor can be admitted to practice only after a clerkship of 7 years with a senior proctor of at least 5 years' standing, and he must produce a certificate of considerable proficiency in classical education. Before the abolition of the probate and matrimonial courts of doctors' commons, the proctors were the only persons allowed to practise in them. (See Doctors' Commons.) According to the original and stricter practice, the proctor's authority to act for his principal must be conferred by a proxy, that is, by an instrument signed by the principal, attested by witnesses, and deposited in the registry of the court. Proxies are still requisite in the ecclesiastical courts; in admiralty they were long ago dispensed with, and a verbal appointment is now sufficient. If the proctor has been regularly admitted to practice, he, like an attorney at law, is presumed in all cases to have authority to appear until his right is disputed. Yet, though the court will presume either his due authority, or at least that he has good reason to believe that those whom he represents have an interest in the cause in issue, it may at any time demand the names of the parties for whom the proctor appears.—Proctors are known in the United States only as officers of the courts of admiralty. In some portions of the country they attend to the whole management of the case from the beginning; in others they conduct the case out of court, while the examination of witnesses in court, the motions, arguments, and other incidents of the trial, are attended to by an advocate. When once retained, the proctor has the whole direction of the cause; but his power may be revoked by the suitor at any time, without cause assigned. This is properly done, under leave of the court, after notice to the proctor, because a proctor is an officer of the court. As he is invested with large discretionary power and influence, the proctor is held to the utmost good faith and integrity. Unless a case is in his opinion just, or at least doubtful, he ought not to bring it before the court. This principle is especially applicable in the case of suits by seamen, where generally no available responsibility is incurred by the libellants. Indeed, for any merely experimental or wanton litigation, or for any want of good faith toward the court, or of fair dealing toward the opposite party, the proctor may be punished by the court. For "sharp and hungry practice" Sir William Scott condemned a proctor to pay the costs of his client's suit; and he added that he was perhaps dealing too temperately in not going further. The duty of the courts of the United States to repress abuses of this nature is enjoined by a special statutory provision, the act of 1813 enacting that if any proctor or attorney shall appear to have [illegible] trolled the proceedings in a case so as to increase the costs unreasonably and vexatiously, the court may order him to pay the excess of tial expense. After a suit is commenced, the respondent has not as a general rule the right to settle the case without the knowledge of the proctor of the libellant; and if he does so, the settlement may be inquired into by the court. The proctor may generally be considered so far *dominus litis*, that he is authorized to make an affidavit of any fact upon which to offer a motion, especially if the fact be peculiarly within his own knowledge. But he cannot release or compromise a claim without special authority. He may however receive payment and the amount so paid is a discharge *pro tanto*. After a decree, unless by special authority of the court, the proctor has no power except to sue out and enforce execution.—The name proctor is also given in England, and in some American colleges, to university officers whose business it is to guard the morals and order of the university.

PRODICUS, a Grecian sophist, a native of Iulis in the island of Ceos, who flourished in the latter part of the 5th century B. C. Plato represents his instruction as chiefly ethical. He regarded the gods as only the personification of whatever contributes to the comfort of human life, and it is stated by Suidas that he was condemned to drink hemlock as a corrupter of the youth of Athens; but this is doubted.

PROGRESSIVE FRIENDS, the name first adopted by a religious society formed by a convention held in Salem, Columbiana co., Ohio, in Sept. 1852, and composed chiefly, though not exclusively, of persons previously identified with the Hicksite branch of the society of Friends. Previous to this time, the Indiana, Ohio, and Genesee yearly meetings of Hicksite Friends had been divided upon questions connected with slavery, and the minorities, which had either seceded or been cut off, had formed new associations, one at Green Plain, Ohio, and another at Waterloo, N. Y., adopting the name of Congregational Friends. The formation of the society of Progressive Friends at Salem, Ohio, was a more complete development of the principles which found expression in the earlier associations, and its name is now widely accepted as the appropriate designation of all those who avow their sympathy with these principles. In 1853 a large society or yearly meeting of Progressive Friends was formed in Chester co., Penn. The society at Waterloo, N. Y., adopted the name, and similar associations were soon afterward formed in various places, some of them taking the name of Friends of Human Progress, instead of Progressive Friends. There are now 5 or 6 yearly meetings and many smaller associations, bearing one or the other of these names, in different parts of the country. These societies have no creed, written or unwritten, as a basis of fellowship. They invite to membership and coöperation all who recognize the equal brotherhood of the human family, and acknowledge the duty of defining and illustrating their faith in God, not by assent to any form of theological opinion or doctrine, but by lives of personal purity and works of beneficence. They hold that churches are not divine but human organizations, possessing no higher powers than those which they derive from the persons of whom they are composed. They have no ordained ministers or elders, and no prescribed ceremonies or forms of worship, but aim to preserve the liberty of speech and of conscience to the fullest extent.

PROJECTILES. See Gunnery, vol. viii. p. 577, and Mechanics, vol. xi. p. 322.

PROMETHEUS, in Grecian mythology, the son of the Titan Iapetus by Clymene, and brother of Atlas, Menœtius, and Epimetheus. According to Hesiod, the gods and men were in a dispute at Mecone in regard to duties and privileges, and especially as to what portion of the animal should be offered to the former in sacrifice. Hereupon Prometheus divided a bull into two parts, wrapping up the flesh and intestines in the skin for one, and the bones covered with the fat for the other. Jupiter, having then been asked which of the two he would choose, decided for the latter, and the choice made could not be revoked. Indignant at the deceit practised upon him, he withheld fire from mortals; but Prometheus stole fire from heaven in the hollow of a tube. Jupiter now sent Pandora to earth with her box of evils, and fastened Prometheus to a pillar, where he remained for many generations, an eagle every day feeding upon his liver, which every night grew again. At length Hercules was permitted to kill the eagle and to free the prisoner. In Æschylus, Prometheus appears not only as the protector of the human race against the superior might of the gods, but as its teacher and benefactor. Through his assistance, Jupiter overcomes the Titans; but when he frustrates the design of destroying mankind, he is chained to a rock in Scythia. There he is visited by the Oceanids and by Io, to whom he foretells his long wanderings. But he is in possession of knowledge which it is essential to the safety of Jupiter to gain; and aware that his help is yet to be invoked, he bids defiance to his persecutor, and refuses to make known the fact. He is hurled hereupon into Tartarus, and afterward reappears chained to Mount Caucasus, and undergoes fresh torments. From this condition he can only be freed when some other god shall voluntarily descend into Tartarus for him, which was finally the case when Chiron, wounded by Hercules, sought permission to go into Hades. Still another account says that Jupiter himself delivered Prometheus when the latter agreed to reveal the prophecy, according to which, if he were married to Thetis, she would give birth to a son stronger than himself. The most celebrated drama founded upon this myth is the trilogy of Æschylus, of which the *Prometheus Vinctus* and a few fragments of the *Prometheus Solutus* are still extant.

PROMISSORY NOTE, a promise in writing to pay money. When the promise is to pay it to the payee or his order, the note is negotiable, and, as an exceedingly useful and important instrument of business, it is governed by a system of law which is quite peculiar. (See INDORSEMENT, and NEGOTIABLE PAPER.) When not payable to order, or not negotiable, the rules of law applicable to it vary very little from those which are in force generally in relation to written contracts.

PRONOUN. See LANGUAGE, vol. x. p. 295.

PRONY, GASPARD CLAIR FRANÇOIS MARIE RICHE DE, baron, a French engineer, born at Chamelet, near Lyons, in 1755, died July 29, 1839. He was educated at the school of *ponts et chaussées*, went on several scientific missions, became assistant to the civil engineer Perronet, and aided him in building the bridge of Concord at Paris. On the completion of this work (1791), he was promoted to the rank of chief engineer. In the same year he was appointed head of the board of survey (*cadastre*). He superintended the forming of new trigonometrical tables, which he collected in 17 large volumes, now in the library of the observatory at Paris. He meanwhile filled the chair of mechanics at the polytechnic school, and in 1798 was intrusted with the direction of the school of *ponts et chaussées*, which he held until his death. Bonaparte charged him with several important missions to Italy, where, beside improvements in the ports of Genoa, Ancona, and Venice, he undertook works for draining the Pontine marshes and regulating the course of the Po. In 1827 he improved the navigation of the Rhone so as to partially prevent its overflowing. He published many works on mathematics and engineering.

PROPAGANDA, or properly CONGREGATIO DE PROPAGANDA FIDE (congregation for propagating the faith), a board of 25 cardinals founded at Rome in 1622 by Gregory XV. for the support and direction of foreign missions. It has a secretary, who is generally a bishop or archbishop, and a number of priests, advisers, and under secretaries, who hold a consultation weekly. The cardinal prefect of the propaganda is the pope's representative in all matters concerning the affairs of foreign missions, including the final appointment of all bishops in missionary countries. Pope Urban VIII. in 1627 added to the congregation a college for the education of missionary priests, where young men from every country in the world, with the exception of strictly Catholic countries, are educated, and ordained for the missionary work among their fellow countrymen. A celebrated polyglot printing establishment is attached to the propaganda, and beside a full corps of professors, including teachers of many ancient and modern languages, it possesses also a museum of antiquities and curiosities, a handsome church, and a large and select library.

PROPAGATION OF THE FAITH, S FOR THE (*la société pour la propagati foi*), a Roman Catholic missionary s founded at Lyons in 1829. Its plan raise, through a number of committees sub-committees, one cent a week from subscriber, the money being forwarded the central committee at Lyons, by wh funds are apportioned to bishops of the v missionary countries throughout the w The society spread rapidly from Lyons the whole of Europe, and has now p members in almost every country in the w It is sometimes confused with the Roman p aganda, with which however it has n in common except a similar object. Th tral committee at Lyons publishes 6 tim year a serial called the *Annales de la p tion de la foi*, the numbers of which are ily translated into all the European lan and published and distributed among the scribers to inform them of the use made o funds and of the progress of the missi work in different parts of the world.

PROPERTIUS, SEXTUS AURELIUS, a R elegiac poet, born in Umbria about the m of the 1st century B. C. He was rich un agrarian division, in 36 B. C., reduced his tune. He wrote 4 books of elegies, princ addressed to his mistress. He was a great tator of the Greek elegiac poets, chiefly C machus and Philetas. The text of Prop has come down to us in an exceedingly c state. The *editio princeps* was printed in in 1473; one of the best later editions is of Hertzberg (2 vols. 8vo., Halle, 1843–5

PROPHECY (Gr. προφητεια, from π to predict), the prediction of future ev The belief that certain men or classes of m had the faculty of predicting future events be traced in the history of many nations to the remotest antiquity; and it was in part the priesthood who were regarded as endowed with such a faculty. It is, h ever, not common to apply the term proph sying indiscriminately to all instances of alleged faculty of predicting, but it is gener ally restricted to the Old Testament the The name prophet in the languages of Christian nations is derived from the Gre προφητης, by which the Septuagint renders the Hebrew *nabi*. But it is now general agreed among the leading Hebrew scholars that the term of the Septuagint does fully correspond to the primary meaning the Hebrew word, which denotes "inspired A Hebrew "prophet," in the wider sense of the word, was therefore a man who sp by divine inspiration. Sometimes the O Testament uses the word in a bad sense men who only claim to be prophets without being so in reality, and of such as were p sessed of an evil spirit.—The principal func tion of the prophets of the Old Testament was obviously to be the privileged organs thro which God designed to keep up the intercourse of revelation between himself and his people. The prophet is the mouth through which God speaks to the people, and publicly announces, so far as necessary, the secrets into which he has been initiated. (Amos iii. 7.) The prophets therefore frequently call their prophecies words of Jehovah. As they were sent to keep the theocratic people on the right path, and to lead it forward toward the fulfilment of its destinies, their ideas were naturally turned toward the future, and, in accordance with the good or bad conduct of the people, they promised to it reward or punishment, salvation or ruin. Frequently, though for the most part obscurely, they pointed to a glorious completion of the theocracy through a great descendant of David, the Messiah. They also acted as the divinely appointed interpreters of the law given through Moses, and were especially zealous as guardians of the rights of the poor. Their mission, as a body of extraordinary teachers, became especially important in times when the ordinary guardians of the law, the priests, sided with the apostates and idolaters. Their individual labors, which frequently embraced all internal and external affairs of the Hebrew state, were however greatly shaped by particular circumstances, and but few of them were in a condition to labor so efficiently for the prosperity of their people as Isaiah. (See *Hebrews*.)—The peculiar form of their prophetic gift is not sufficiently defined in the Old Testament to leave no room for permanent speculation and controversy. The mode in which the prophet obtained his inspiration was obviously different from that in which inspirations were conveyed to Moses and the apostles. It is intimated as characteristic of a prophet that he obtained divine inspiration in visions and dreams; the name seer, which is usually given to him, points to the same source, and the language of the prophecies, which is highly poetical, well accords with it. Everywhere a sort of ecstatic transport, in which ideas were immediately received from heaven, seems to have been essentially connected with the prophetic state. This forcible working upon the mind of the prophet by the spirit of God is sometimes represented as the stronger, the less godly the life of the prophet was, as in the case of Balaam, and of Saul, who when the spirit of God came upon him threw himself upon the ground, tearing his clothes from his body. On the basis of these statements of the Scriptures, a host of exegetical writers have discussed with great keenness and learning the precise nature of the agency or agencies by which the prophetic ecstasy and inspiration were produced. Many writers, especially since the middle of the last century, have endeavored to show that the Scriptures do not assert a direct and miraculous supernatural interference, and that all can be explained by a high degree of religious enthusiasm and ecstasy. Among these writers are Eichhorn, Knobel (*Der Prophetismus der Hebräer*), Ewald (in an introductory treatise in his work on the prophets), and Dr. Williams (in the Oxford "Essays and Reviews"). With regard to the predictions of future events occurring in the books of the prophets, this class of writers either ascribe them (as Bunsen did) to a kind of spiritual clairvoyance, or they maintain (with Dr. Williams) that very few passages can be claimed as strictly prophetic; that these few cases "tend to melt, if they are not already melted, in the crucible of free inquiry;" and that what is left is certain "deep truths and great ideas." This view of the case is rejected as more or less rationalistic by the great majority of Christian theologians, who maintain that it is opposed by the plain intent of the Old Testament, by the counter testimony of Christ and the apostles in the New, and also by the concessions of unbelieving interpreters, such as Strauss, who say that the scriptural writers undoubtedly claim prophetic inspiration, but that the claim is absurd. Among the ablest works written from this standpoint must be mentioned Professor Fairbairn's treatise on "Prophecy, its Nature and Functions" (Edinburgh, 1856), Delitzsch's *Prophetische Theologie*, and especially Tholuck, *Die Propheten und ihre Weissagungen* (Gotha, 1860), who has reviewed the whole subject in a philosophical manner, and gives as the result of his studies that the prophecies cannot be interpreted "as the utterance of subjective religious aspirations," and that "the very course of history has impressed upon these declarations the stamp and confirmation of an objective and supernatural inspiration." The reader may also consult various commentaries on the books of the prophets, and that class of works which limit themselves to an interpretation of the "Messianic prophecies" throughout the entire Old Testament, among which Hengstenberg's "Christology of the Old Testament" is the best known. Some interpreters have asserted that all or certain prophecies were conditional, and therefore revocable; while the more common opinion is that when the prophet denounces the divine judgments, he proceeds on the assumption that the people will not repent, an assumption which he knows from God to be true.—The proper origin of the prophetic office must be fixed in the Mosaic economy; for although previously Abraham and the body of patriarchs in general are called prophets, because divine communications were made to them in the manner above described, yet they were not clothed with a prophetic office, which from the time of the establishment of the Mosaic law was regularly connected with the prophetic gift, so as to form part of the idea of a prophet. The book of Daniel, though he was eminently endowed with prophetic gifts, was not placed in the collection of prophetic books, because he had not filled the prophetic office. In the age of the judges, prophecy, though existing only in scattered instances, exerted a powerful influence. A more conspicuous prophetic agency begins with Samuel, who seems to have been the founder of the schools of the prophets; for they are mentioned for the first time in his history. Gibea, Rama, Bethel, Jericho, and Gilgal are enumerated as places where such schools existed. They were institutions for training prophets; the senior members instructed a number of pupils, and directed them. Samuel, Elijah, and Elisha are mentioned as principals of such institutions. The pupils are frequently called the "sons of the prophets." The prophets were mostly taken from these schools, yet not always; for Amos relates of himself that he had been trained in no school, but was a herdsman, when the Lord took him to prophesy unto the people of Israel. Sometimes, but rarely, it occurs that women came forward as prophetesses. The golden era of the prophets extends from the time of Samuel to the Babylonian captivity, and hardly any important event happened in which they did not appear as performing the leading part. About 100 years after the return from the Babylonian captivity, the prophetic profession ceased, and Haggai, Zachariah, and Malachi are uniformly mentioned by Jewish tradition as the last of the prophets.—The manner of life of the prophets was conspicuous for strictness, austerity, and asceticism. They shunned the company of the cheerful, and frequently were in poverty and want. As no provision had been made for their support by law, they had to gain their livelihood by other occupations. Some of them appear to have been in possession of considerable physical and medical knowledge, and to have occasionally made use of it. Later they often wrote down their prophecies, and many others compiled historical works. Thus Samuel, Gad, and Nathan wrote the history of David; Nathan also the history of Solomon; Shemaiah and Iddo the history of Rehoboam; Jehu the history of Jehoshaphat; and Isaiah the history of Uzziah and Hezekiah. When the prophetic office ceased, the Jews, according to the Talmud, found some substitute for it in the Bath-Kol. (See Bath-Kol.)—The New Testament mentions the power of prophecy as one of the gifts of the Holy Spirit. We read of one prophet, Agabus, who predicted the famine under Claudius and the imprisonment of the apostle Paul; but generally a foreknowledge and foretelling of futurity is not mentioned as characteristic of those men who, as Barnabas, Judas, and Silas, are called prophets in the Pauline epistles. The object of the Christian "prophecy" was, according to 1 Cor. xiv. 3, "edification and exhortation and comfort." Among the books of the canon of the New Testament only one, the Revelation, bears a prophetic character.

PROPHETS, Books of the, a part of the Old Testament. The rabbis divided the books of the Hebrew canon into three classes: 1, *Torah* (law); 2, *Nebiim* (prophets); 3, *Kettubim* (writings, hagiographa). The second class was subdivided by them into "former" and "latter" prophets. The former comprised the books of Joshua, Judges, Samuel, and Kings. Among the latter they again distinguished between the "great" (Isaiah, Jeremiah, and Ezekiel) and the 12 "minor" prophets (Hosea, Joel, Amos, Obadiah, Jonah, Micah, Nahum, Habakkuk, Zephaniah, Haggai, Zechariah, and Malachi). In the arrangement of modern biblical criticism, Joshua, Judges, Samuel, and Kings are not counted among the books of the prophets, which are divided into the 4 great (Isaiah, Jeremiah, Ezekiel, and Daniel) and the 12 minor prophets. For a fuller account, see the articles upon the individual prophets.

PROPONTIS. See Marmora, Sea of.

PROPORTION, in mathematics, the relation of one quantity to another. This relation may be expressed either by the difference of the quantities or by their quotient. In the former case it is called arithmetical relation, in the latter geometrical proportion, or simple proportion. The measure of this latter relation is called the ratio; that is to say, ratio is the number of times one quantity contains another taken as a standard. The following algebraic expression is called a proportion: $a : b :: c : d$, which means that the ratio of a to b is the same as the ratio of c to d. A proportion may thus be defined to be an identity of ratios. In the above expression a, b, c, and d are called the terms of the proportion; a and d the extremes; b and c the means; a and c, antecedents; b and d, consequents.

PROSERPINE, or Persephone, in Greek and Roman mythology, the queen of the infernal world. She was the daughter of Jupiter and Ceres, and was beloved by Pluto, who forcibly carried her off to Hades. There she was found by Ceres, who induced Pluto to consent that her daughter should pass 8 months of every year in the upper world with her. Through this story Proserpine became with the ancients a symbol of vegetation. The Eleusinian mysteries belonged to her in common with her mother, and she had temples at Corinth, Megara, Sparta, and at Locri in the south of Italy.

PROSODY (Gr. *προσῳδια*), that part of grammar which treats of quantity, accent, versification, and the laws of harmony in metrical composition. In the modern European languages prosody has to do almost wholly with accent, but Greek and Roman versification was governed by the quantity of syllables, that is, the length of the vowels in them. In English prosody the adjectives "long" and "short" are used respectively to denote accented and unaccented syllables, and these are indicated by the signs – and ⏑. A group of syllables taken together is called a measure. The different kinds of measure are the following: iambus, ⏑ –; trochee, – ⏑; spondee, – –; pyrrhic, ⏑ ⏑; dactyl, – ⏑ ⏑; amphibrach, ⏑ – ⏑; anapæst, ⏑ ⏑ –. Metre consists essentially in the recurrence at certain intervals of syllables similarly accented, or in other words of the arrangement of measures according to certain rules; and metres are demominated from the kind and ngement of the measures of which they are posed. The iambus forms the iambic ometer, dimeter, trimeter, tetrameter, pen-ater (heroic measure), hexameter (Alexan-e), and heptameter, in which the measure rs respectively from one to seven times ach verse. There are the same varieties rochaic measure; the dactyl, amphibrach, anapest have the first four, and there is a dactylic hexameter so called, the last sure of which is a spondee. Longfellow's angeline" is written in this metre. Most se metres admit of an additional unaccented able at the end of the line, and sometimes e beginning, as in the following amphibrach ameter from Goldsmith:

aks, my lord, for | your venison; | for finer | or fatter
er ranged in | a forest | or smoked in | a platter.

the amphibrach and dactylic measures a syllable is sometimes wanting; thus:

Ye shepherds | so cheerful | and gay.
Peace to thee, | isle of the | ocean.

ombination of several lines constituting a lar division of a poem is a stanza, and stan- may combine a variety of measures. The serian stanza consists of 9 iambic lines, first 8 being heroics and the last an Alex-rine. Gay's stanza contains 8 iambic tri-ers, the 1st, 3d, 5th, and 7th lines having additional final syllable. Elegiac octosyl-s are iambic tetrameters with alternating mes; octosyllabic couplets, iambic tetrame- with pairs of rhymes, one foot occasionally g a trochee; octosyllabic triplets, iambic ameters with 3 rhymes regularly in suc-ion; heroic couplets and triplets, iambic ameters with rhymes in pairs or triplets; iac heroics, the same with alternating mes; rhymes royal, 7 heroics, of which the 2 rhyme with each other, and the re-ing 5 may be made to rhyme in various s; and *ottava rima*, 8 heroics, the first 6 ming alternately, and the last 2 in suc-ion. *Terza rima*, which has been bor-ed like the last from the Italian, consists ambic pentameters in which the following es rhyme with one another: the 1st and the 2d, 4th, and 6th; the 5th, 7th, and and so on; the stanza ends abruptly, and last rhyme, like the first, is on a couplet ead of triplet. This is the metre of Dante's *ina commedia*. Ballad stanzas are of 4 iam- lines, the 1st and 3d being tetrameters and 2d and 4th trimeters. Service or common re consists of iambic heptameter couplets, h may be divided into ballad stanzas. g metre is a stanza of 4 iambic tetrameters, ming either in couplets or alternately; and t metre 4 iambic lines, of which the 1st 3d are trimeters and the 2d and 4th tetra-ers. There are several other kinds of ra in more or less frequent use, one of the t curious of which is the old "poulterer's sure," consisting of Alexandrines and iam- heptameters alternately.

PROTAGORAS, a Greek philosopher, born in Abdera probably about 480 B. C., died about 411. The common story in regard to his origin was that he was a porter, and attracted, by the skilful manner in which he carried his load, the attention of Democritus, who undertook the task of educating him. He travelled throughout Greece, giving instructions in philosophy to large numbers of pupils. Twice at least he visited Athens, and seems to have been on intimate terms with Pericles. He was the first who assumed the title of sophist, as denoting one who instructed others in the art of becoming wise, and in the arts of eloquence and politics, and was also the first who received pay for his lessons. According to Plato, he received more money during the 40 years in which he taught than Phidias and 10 other sculptors. None of his works are extant. In his treatise "On the Gods," Protagoras started with the following proposition: "Respecting the gods, I am unable to know whether they exist or do not exist." For this statement he was banished from Athens, where he was then residing, and his books were burned. According to some he was drowned on a voyage to Sicily.

PROTECTOR, LORD, in English history, a title conferring extraordinary powers, which has been several times conferred by parliament during political emergencies. The most celebrated lord protectors were Richard, duke of Gloucester, whose protectorate ended in his becoming king as Richard III.; Edward Seymour, duke of Somerset, uncle to Edward VI.; and Oliver Cromwell and his son Richard.

PROTESILAUS, a Thessalian prince, the first Greek slain in the Trojan war. It is said in the Iliad that he was the first who leaped from the ships upon the Trojan shore, and according to the ancient tradition recounted in Lucian he was killed by Hector. The great affection toward Protesilaus of his wife Laodamia is celebrated by the poets. After his death she prayed to be permitted to converse with him only for the space of 3 hours; the prayer was granted, Mercury conducted Protesilaus to the upper world, and when he died a second time his wife died with him.

PROTEST (Lat. *protestor*, to testify or declare against), a term used in many ways and for many purposes. One who is called upon to pay an import duty, a tax, a subscription, or the like, which he thinks he ought not to be required to pay, but is unwilling to encounter the delay and expense of a lawsuit at that time, pays the sum demanded under protest; that is, he accompanies the payment by a written and attested declaration of what he deems the illegality of the demand, and of his rights of defence and denial. This protest preserves all those rights; and in any subsequent suit or other effort to get the money back, the protest will prevent him from being impeded by his payment.—In legislation, the members of a deliberative body who dissent from the views of a majority, and have no power to prevent those views from going into effect, sometimes ask leave to put on the record of the body a declaration of their views, drawn up and signed by them. This is called their protest against the measure; and leave to record it is usually given, if it be decent and temperate in its terms, and does not state what the majority regard as wilfully false or impertinent.—If a vessel be wrecked, or meet with other injury from any peril of the sea, it is an ancient and nearly universal custom for the master, on his arrival at port after the injury, to appear before a notary public, or some competent magistrate, or in their absence some respectable and qualified person, and enter his protest against the accident or peril. In this protest he details the circumstances with sufficient fulness to sustain his declaration that the injury occurred, not through the fault of the vessel, but by reason of the peril stated. In the absence or disability of the master, the protest is made by the officers, or even by the seamen; and when it is made by the master, he is usually accompanied by one or more of the officers, and by some of the seamen.—A very important use of protest is made in the case of dishonored bills of exchange. (See EXCHANGE, BILL OF.) It is a universal law that a foreign bill of exchange, if not accepted, or if not paid at maturity, must be protested in order to hold all the parties to it. In this sense, the states of the Union are foreign to each other. Inland (or domestic) bills and promissory notes are often protested in the same way; but this usage, so far as it exists, has grown up from the convenience of it, and not from any requirement of the law merchant. The protest should be made by a notary public; and full faith is given in all countries to all the official acts verified by his seal, which acts are required by law merchant. He cannot properly delegate this power to any clerk or substitute. An acceptance or payment *supra* protest takes place when, a bill having been protested, a third person intervenes, and accepts or pays the bill for the honor of the party whose duty it was to accept or pay it; and this gives him a right to indemnity from the person for whom he accepts or pays. An acceptance or payment *supra* protest is sometimes called an acceptance or payment for honor. Generally, where one accepts or pays for honor without designating for whose honor he acts, it will be deemed that he acts for all who were bound by the paper, and he acquires his right of indemnity against all whom he thus protects. But he may designate, if he choose to, the party for whose honor he acts, and then he protects only that party, and has no claim or rights against any other.

PROTESTANT, a collective name for a large class of Christian denominations, embracing in general all except the Roman Catholic and eastern churches. The name originated in 1529 in Germany, at the diet of Spire. The majority of the members of the diet, in union with the representative of the emperor,
had passed a resolution that those estates w
had shown themselves favorable to the
mation should prohibit, until the conv
of an œcumenical council, all further in
tions in religious matters, and in par
should not allow any alteration in the
bration of the Lord's supper or the mass
this resolution the evangelical estates,
ing of the elector of Saxony, the mar
of Brandenburg, the duke of Brunswick-L
burg, the landgrave of Hesse, the prin
Anhalt, and 14 imperial cities, refused t
mit. They declared their readiness to
the emperor and the diet in all "duti
possible matters;" but against any ord
sidered by them repugnant to "God an
holy Word, to their souls' salvation an
good conscience," they entered, on Apr
solemn protest. Henceforth they were
the Protestants. The origin of the name
defines its original signification. The
of the first protest did not fully agree
their theological views; but they did ag
the protest against the authority of secu
ecclesiastical boards to compel obedien
matters of faith, and the name Protestant
fore came early into use as the col
name for all the Christian denominat
Switzerland, France, England, Scotland
land, and other countries which proclaim
Bible to be the only rule of faith.—The ag
gate number of the Protestant popula
the five great divisions of the world may be
from the following figures, taken from
"Ecclesiastical Year Book" for 1859:

I. AMERICA.—British America, 2,200,000; United S
21,000,000; South America, 20,000; Dutch p
85,500; Danish and Swedish possessions, 55,
2,000; total, 28,812,500.

II. EUROPE.—Portugal, 7,000; Spain, 5,000; France,
Austria (including Venetia), 8,868,152; Prussia
898; the other German states, 11,240,176; Italy
Switzerland, 1,417,754; Holland, 1,990,304;
25,000; Great Britain (including Gibraltar, M
Helgoland), 22,000,000; Denmark (including
1,887,000; Sweden and Norway, 5,067,000;
8,918,000; Turkey, 10,000; Ionian isles, 2,00
62,827,206.

III. ASIA.—Asiatic Russia, 40,000; China (with Hong K
10,000; East Indies (with Ceylon and Ind
800,000; Asiatic Turkey, 6,000; Indian arc
50,000; Persia, 1,000; Arabia (with Aden), 2,0
409,000.

of southern and western Africa, 400,000; Algeria
Egypt, 2,000; Liberia, 50,000; total, 712,000.

V. AUSTRALASIA and POLYNESIA, 1,820,000.

Total in all five divisions of the world, 88,080,706.

PROTEUS (Laurenti), or *hypochthon* (Mer
a perennibranchiate batrachian reptile, be
ing to the same family as the axolotl and
menobranchus. The skin is naked and sli
the body elongated and cylindrical, and
tail short, broad, and compressed laterally;
branchial tufts are 3 pairs, and persistent
ing life; legs 4, rather weak, the anteri
toed and the posterior 4-toed. The com
proteus (*P. anguinus*, Laur.) is about a
long and ½ inch in diameter; it is pale fle
colored or white, with the branchial
bright crimson; the teeth are small and
in both jaws and on the palate; the head

gular, and the snout obtuse; the eyes are ry small, and without lids. It is found only the subterranean waters of some caves of urope, as in Carinthia, Carniola, the Tyrol, nd especially in the Adelsberg cavern in Carniola. The respiration is essentially aquatic y means of the branchial tufts, though it has dimentary lungs, rises to the surface to swalw air, and can live a short time out of the ater, like the menobranchus; its motions by eans of the legs are sluggish and awkward, ut it swims with considerable rapidity and se by the lateral undulations of the tail and ody; when the water of its subterranean reeat becomes low, it buries itself in the mud, ke others of the family; the food consists of quatic worms and insects, and soft-shelled ollusks. Several local varieties occur, generlly considered as belonging to the same speies; one of these is of a purplish color with ellow spots, and larger, widely extended, and oarsely divided gills; these are described as pecies of *hypochthon* by Fitzinger in the *Sitzungsberichte* of the academy at Vienna for Oct. 850, pp. 291-303. (For the fish called the roteus of the lakes, see MENOBRANCHUS.)

PROTEUS, in Greek and Roman mythology, sea god subject to Neptune, whose flocks he ended. He had the gift of prophecy. At idday he always arose from the flood and lept in the shadow of the rocks on the coast, and those who desired him to foretell the future were obliged to seize him at that time. In his ndeavors to escape he would assume various hapes to terrify or disgust, and thus drive way his questioner; but when he found this ubterfuge of no avail, he would return to his proper shape and yield to the demand.

PROTOGENES, a Greek painter, who flourished toward the close of the 4th century B. C. He was born at Caunus in Caria, and for 50 years lived unnoticed and poor at Rhodes, until through the intervention of Apelles the Rhodians became aware of his merit. When Demetrius Poliorcetes besieged the city, he was careful not to attack the most defenceless part, because it contained the works of Protogenes. He spent so much time in the elaboration of his works, that Apelles said he never knew when to take his hand off his picture. The Ialysus was considered his masterpiece, and this when Pliny wrote had been carried from Rhodes to Rome, and was there preserved in the temple of Peace. Protogenes was also a statuary, and according to Suidas wrote on art.

PROTOZOA, a division of invertebrate animals proposed by Siebold, and since adopted by Leuckart and Vogt, but denied by other naturalists. As generally defined, it contains the foraminifera, polycystina and rhizopoda generally, the sponges, and the true infusoria, which may be characterized as having a simple or structureless organization, reducible to a cell or cell contents, without any distinct separation of systems of organs. Prof. Agassiz, adhering to Cuvier's 4 great fundamental branches of the animal kingdom, neither more nor less, viz., vertebrates, articulates, mollusks, and radiates, could not admit a 5th, the protozoa, and accordingly, in the "Essay on Classification," distributes the animals thus named partly among plants (algæ), and partly among embryonic forms of acephalous mollusks, worms, and crustaceans; it having been ascertained that the corallines are algæ with more or less lime in their structure, and that there is hardly a group among the lower animals and plants which does not contain simple locomotive individuals (though in the latter the locomotion is not voluntary), as well as free and fixed compound communities, he is inclined to associate the rhizopods with algæ, which have ovoid masses somewhat resembling the germinal granules of the former. This group is called *protozoa*, as representing the first step in animal organization, and oozoa by Carus from their analogy to the ova or germs of the higher classes.

PROUDHON, JEAN BAPTISTE VICTOR, a French jurist, born at Chasnans, department of Doubs, in 1758, died in Dijon in 1838. During the revolution he was judge at Pontarlier, assistant deputy to the legislative assembly, and afterward a member of the civil tribunal at Besançon. In 1802 he delivered free lectures on law, which attracted considerable attention; in 1806 he was appointed professor of civil law in the school of Dijon, and in 1809 became dean of the faculty. On the return of the Bourbons he was removed from this post; but none of his colleagues having consented to take it, he was restored. His works, in 21 volumes, are among the treasures of French jurisprudence.

PROUDHON, PIERRE JOSEPH, a French political writer, born in Besançon, July 15, 1809. He is the son of a cooper, and after studying for some time, through the assistance of some benevolent persons, at the college of his native city, became apprentice to a printer, and in 1837 was taken into partnership by a printing firm at Besançon. Having devoted much of his leisure to study, and particularly to philology, he published an edition of the Bible with annotations upon the principles of the Hebrew language, and reprinted Bergier's *Éléments primitifs des langues* (1837), with an anonymous *Essai de grammaire générale*, by himself, as an appendix. This essay, afterward reprinted in separate form (1850), received from the academy of that city a prize consisting of a pension of 1,500 francs, which enabled him to visit Paris. Here he became a contributor to Parent Desbarres' *Encyclopédie Catholique*, and wrote for the Besançon academy a prize essay, *De la célébration du dimanche* (1840), and a paper entitled *Qu'est-ce que la propriété?* This pamphlet, which opened with the afterward celebrated dictum, *La propriété, c'est le vol*, was censured by the academy, who at once cut short Proudhon's allowance, and would perhaps have brought him before a court of justice had not the economist Blanqui, who had been appointed to examine it, declared that he found nothing objectionable in it. It was followed in 1841 by another pamphlet upon the same question, and in 1842 by an *Avertissement aux propriétaires*, for which he was arraigned before a jury at Besançon, but acquitted. In the same year he quitted the printing business and became director of a company of freight boats on the Saône and Rhone. In the mean time he continued to propagate his opinions in his *De la création de l'ordre dans l'humanité* (1843), presenting the theory of a new political organization, and *Système des contradictions économiques* (2 vols. 8vo., 1846). On the breaking out of the revolution of Feb. 1848, he was engaged in the publication of his *Solution du problème social*, a plan of social reform by means of a new organization of credit and monetary circulation. On April 1 he became the editor of *Le représentant du peuple*, a daily journal of radical opinions, through which he gained considerable popularity. On June 4 he was elected deputy to the constituent assembly, and was accused of being implicated by sympathy and advice in the bloody contest that took place toward the close of that month, but the accusation was not sustained. On July 31 he came forward in the assembly to urge a proposition which he had previously made for the establishment of a progressive income tax, the design of which was the abolition of interest on capital, and eventually the consolidation of the republican government. This was almost unanimously voted down by the assembly, "as an odious attack upon the principles of public morality and an appeal to the worst passions." He closed his parliamentary career by opposing (Nov. 4) the adoption of the constitution, which he looked upon as "dangerous to liberty." He now returned to his former pursuit, and edited in succession 3 short-lived journals: *Le peuple*, from Nov. 23, 1848, to April, 1849; *La voix du peuple*, from Oct. 1, 1849, to May 16, 1850; and *Le peuple de* 1850, from June 15 to Oct. 13, 1850. These papers, rash and violent in their tone, were repeatedly condemned by the courts, but the fines imposed upon the editor were immediately paid by subscriptions from that portion of the people who admired him as the harbinger of social revolution. His printed speeches and pamphlets, including his *Droit au travail* (1848), *Les Malthusiens*, *Démonstration du socialisme*, and *Idées révolutionnaires*, found a ready sale among men of all opinions, and elicited answers from the ablest pens among the conservative party. As early as Jan. 1849, he had undertaken to establish *la banque du peuple*, an institution of gratuitous credit, by means of which he hoped to bring his theory into operation; but in this he was interrupted, March 28, by a sentence of 3 years' imprisonment for illegal publications, which he at first avoided by flight. After sojourning in Geneva for a few months, he delivered himself up (June 4), was incarcerated successively in the Conciergerie, at Doullens, and in the prison of Ste. Pélagie, where in 1850 he married a merchant's daughter. During his imprisonment he wrote *Confessions d'un révolutionnaire* (1849); *Acta de la révolution* (1849); *Gratuité du crédit* (1850); and *La révolution sociale démontrée par le coup d'état* (1852), which created a deep sensation and was looked upon as a partial apology for Napoleon's policy. Liberated June 4, 1852, Proudhon remained for a while in retirement; but in 1856 he reappeared with a *Manuel des opérations de la bourse*, a satire on stockjobbers and speculators; and soon afterward published *De la justice dans la révolution et dans l'église, nouveaux principes de philosophie pratique* (3 vols., 1858), which he ironically dedicated to the archbishop of Besançon. This metaphysical work, a covert attack upon the established order of things, was seized by the police, and its author was sentenced to 3 years' imprisonment and a fine of 4,000 francs. The amnesty granted to the press by Napoleon III. set him at liberty. His latest work is entitled *La paix et la guerre* (2 vols., 1861).

PROUT, Samuel, an English water-color painter, born in Plymouth, Sept. 17, 1783, died Feb. 10, 1852. In early life he was a companion of Haydon. Some sketches of Cornish scenery which he executed for Britton the antiquary first brought him into notice, and in 1805 he removed to London. In 1818 he visited the continent for the first time, and in the mediæval architecture of Rouen and other old Norman cities discovered a class of subjects singularly suited to him. Thenceforth he devoted himself to architectural subjects, visiting the oldest cities of France, Switzerland, Germany, the Netherlands, and Italy, and making sketches of quaint streets and market places, and picturesque buildings. His spirited "Facsimiles of Sketches made in Flanders and Germany" (fol.), "Sketches in France, Switzerland, and Italy" (fol., 1839), with other series of lithographic copies of his sketches, have made this class of his works widely known. He also published a series of studies and drawing books for pupils; "Antiquities of Chester" (imp. 4to.); "Hints on Light and Shade, Composition, &c., as applicable to Landscape Painting" (fol., 1838); "Microcosm, the Artist's Sketch Book of Groups of Figures, Shipping, and other Picturesque Objects" (fol., 184[illegible]); "Hints for Beginners," &c.; beside making drawings for annuals and other works. The "Art Journal" for 1849 contains a memoir of him by Ruskin, who ranks him among the first of water-color painters.

PROUT, William, a Scottish physician and chemist, born in 1786, died in London, April 9, 1850. He received his professional education at the university of Edinburgh, but passed the greater part of his life in London. His researches on the application of chemistry to the explanation of the phenomena of life are contained in an important work entitled "On the Nature and Treatment of Stomach and Renal Diseases" (5th ed., 1848.) He also published

Chemistry, Meteorology, and the Function Digestion considered with reference to Nat- al Theology," a Bridgewater treatise; "An quiry into the Nature and Treatment of ravel," &c.; and a number of papers in the ientific magazines and transactions of various cieties. He is considered the pioneer in the ovement which has so intimately connected emistry with the treatment of disease.

PROVENÇAL POETRY, the name given to e literature which prevailed in the south of rance and adjacent countries from the end of e 11th to the middle of the 14th century. lthough these are the limits within which it ordinarily confined, its existence dates as r back as the 8th century, when the Romance iom of the south began to take the place of e Latin. In that part of the country traces the Græco-Roman paganism, such as popular orts and dances, accompanied with amatory d licentious songs, could be found long af- r paganism itself had passed away. After renuous efforts the clergy found themselves able to put an end to these practices, and tempted to sanctify them by adapting them the ceremonies of the Christian faith. The lemnities of public worship were dramatized, d a visible representation was given to the cts and incidents in the early history of the urch. Accompanying these ceremonies rang up a popular poetry, a vague recollec- on of the hymns of the old religion. The nguage, the Romance Provençal or *langue* c, was based upon the Latin, but a Latin rrupted by popular usage and by collision ith the 5 ancient tongues of Gaul. Into this ialect were moreover adopted Greek, Teu- nic, and Arabic words. It became gradually xed and polished, partly by the pious songs the monks, and as early as the year 1000 oems were written in it, which at that time ere celebrated, although very little from that eriod has come down to us. From the people e poetry of the vulgar tongue ascended to e courts and castles. By the end of the 11th entury the language had become fixed, with a eterminate grammar, and with considerable ower of expression, and it contained poetical ompositions, with a system of versification ounded on a combination of rhyme with the yllabic accent. The word *trobar* (Fr. *trouver*, o find, to invent) was in use to denote the cre- ative act of the imagination, and from it the itle of troubadours was given to those who ultivated poetry. Under such circumstances he Provençal literature entered at the opening of the 12th century on a course of rapid development, in which it was materially favored by he condition of the country. The south of France for several centuries had been and continued to be comparatively undisturbed by the wars which laid waste other parts of Europe. The Visigoths and Burgundians who settled in it were by far the most civilized of all the barbarian races. In 879 the kingdom of Arles was founded by Boson, and was ruled by his descendants, 12 princes of the Burgundian line, until 1112, when the crown of Provence came into the possession of Raymond Bérenger, the third count of Barcelona. Under the new political division the south of France was as peaceful and as prosperous as under the old, and before the end of the 12th century the fame and the poetry of the troubadours had penetrated into nearly every country in Europe. The *gai saber* or "gay science," as that literature was called, according to the doctrines of which love was the principal of all virtue and of all glory, was chiefly protected and encouraged in the courts of Provence, the country in which it sprang up, in the dominions of the count of Toulouse, and in the kingdom of Aragon, which in 1137 became subject to the counts of Barcelona. But it was also popular in many other courts, especially in that of Castile. The language itself was the dominant one in all France south of the Loire, and also prevailed in Catalonia, Valencia, part of Aragon and of the north of Italy. Castilian writers attribute the origin of their poetry to the Provençal, or, as they term it, to that of the Limousin; while in Italy, long after the troubadours themselves had passed away, their works were admired and imitated. The poems upon which their celebrity chiefly rests are lyrical. They are divided into symmetrical strophes, and the system of versification was carried to the highest degree of refinement and intricacy. Moreover, in no other literature, except the Arabic, has the taste for rhyme been carried to so great an extent. As the poems were written to be sung with a musical accompaniment composed by the poet himself, there early sprung up a class called *jongleurs* (Lat. *joculatores*), who made it their business to recite the songs of others and sometimes their own. Of these some led an independent life, making their way into courts, castles, and all places where bodies of men were assembled; others were in the personal service of some distinguished troubadour. To the jongleurs, and the manner in which they made a trade of their art, the troubadours themselves attributed the decay of their poetry, although the profession of jongleur was at one time a kind of poetic apprenticeship, which custom required almost invariably to be imposed.—Of the numerous varieties of lyric composition cultivated by the troubadours, the most important were the following. 1. The *canso* (chant or chanson) or chivalric love song, in which they celebrated the beauty or virtue of their ladies, or gave expression to chivalric passion. In numbers and importance poems of this form far exceed those of all others, as the canso was considered superior to all other kinds of amatory poetry. 2. The *sirventes*, or satires, were all poems which either had not love for their subject or did not treat it seriously, but more particularly those in which the troubadours assailed the vices of their age, abuses in the church, or the brutalities of the feudal lords. In this form they were very bold, being deterred by no considerations of fear from denouncing acts of injustice. 3. Historical pieces, sometimes included also under sirventes, usually in reference to the crusades in the East or against the Arabs of Spain, or depicting the contests of the smaller feudal powers. Under this head was included the *prezicansa* or poetical exhortation to enterprises of this kind. Poems of this sort were usually recited by the jongleurs. 4. The *tensons*, or poetic combats, in which two or more interlocutors are represented as supporting opposite sides on some point in the philosophy of chivalric love. This, though a favorite, was necessarily the most didactic and the least poetical form in which their productions were written. Under it were included the *partimen jocx-partitz* or *partia* and the *tourneyamen*. 5. The epistles, in which they treat of love, friendship, and also of moral and religious subjects. The *donaire*, *saluts*, *ensenhamen*, and *conte* were varieties of this form. 6. The *planh*, a kind of elegy, in which they celebrate the memory of a fallen knight or the disappointments of love. 7. The *balada*, the ballad and the round, little poems sung by an indefinite number of persons, and accompanied with dancing. Compositions of this form seem to have been abandoned to the women. 8. The *serenas*, or serenades, and the *albas* or *aubades*, waking songs, poems of a remarkably delicate and impassioned character, very few of which have come down to us. The latter were put into the mouth of one of the parting lovers, or of one of the companions of the knight, or generally of a sentinel giving warning of the coming of the day. 9. The *pastoretas* or *vaqueyras*, pastorals, which usually recited conversations between discreet shepherdesses, tending a few lambs, and troubadours riding by, in which the latter utter compliments they do not mean, and to which the former are careful not to attach any value. The 3 last forms were of a more popular character than the others, being rarely or never heard in the courts, and constitute a distinct group in the system of Provençal poetry. There were a large number of other terms in use by the troubadours, either synonymous with those mentioned or denoting other varieties of poetic compositions. Beside these lyrics there were narrative poems, the most ancient of which were based upon some incidents connected with the first crusade. But the Provençal was wanting in dramatic compositions, or if they existed even in a crude form none have come down to our time. The decline of the literature was marked toward the close of the 13th century by the composition of "treasuries," written in verse, and containing an account of human knowledge as it then existed, and also by the production of histories and chronicles, some of which were in prose. The most remarkable fact in connection with the "treasuries," the encyclopædias of their age, was their narrow range of knowledge.—William IX., count of Poitou (died 1127), though not the most ancient of the troubadours, first whose works have come down to us, entire or in fragments, and is therefore placed at the head of the Provençal Brave, active, and a libertine in private, "he understood," say the biographical notions of the troubadours, "the art of making verses and of singing to perfection, and about the world a great while in order to impose upon the ladies." Giraud de Borneil, the greatest of the Provençal poets, according to the decision of his contemporaries, and those speaking his language; but this was disputed by Dante and the Italian poets of the 14th century, who awarded the palm Arnaud Daniel. Among the names of and nobles prominent as troubadours are of Richard Cœur de Lion and his contemporary Bertrand de Born, who acted so conspicuous part in fomenting civil war between the members of the royal family of England, and obtained an unpleasant immortality Dante, by whom he is placed in hell with head severed. Beside these, some of the celebrated were Arnaud de Marveil, attached to the court of Roger II., viscount of Beziers, called Taillefer; Rambaud de Vaqueiras, distinguished as a warrior as well as a poet, who was made a knight by Boniface I marquis of Montferrat; Pierre Vidal of Toulouse, who accompanied Richard of England on the third crusade; Pierre Cardinal of in Velay, the greatest satirical writer of troubadours; and Giraud Riquier of Narbonne, who belonged to the court of Alfonso X Castile. Moreover, among the poetical works of the Provençal troubadours which still remain, are to be found compositions by women, some of whom were ladies of high rank. They were called *trouveresses*, and most of flourished within the second half of the century.—The decline of Provençal poetry, which began about the middle of the 13th century, was due partly to defects inherent itself, but chiefly to political causes. The ignorance of the troubadours was amazing. Scarcely an allusion can be found in their works to the mythology or history of the ancients, and the treasury of Pierre de Corbiac, evidently regarded by its author as displaying a miraculous erudition, mentions only the name of Ovid among the Latin poets, and him calls a liar. The language and poetry of Provence rapidly declined in the crusade against the Albigenses, and the wars which during the first half of the 13th century desolated the south of France. The sovereign families, the great patrons of the troubadours, disappeared. The family of Provence failed in 1245, and the territory possessed by it was claimed by Charles of Anjou; in 1249 the house of *Toulouse* also became extinct. From this time the Provençal poetry rapidly declined, and its fall was hastened by the hatred felt for it by the church. In the contests between the clergy and the feudal lords, the troubadours had rarely failed take the side of the latter, and in the war xtermination waged against the Albigenses cely any of them were found on the side the crusaders. In 1245 Innocent IV. issued ull, in which he called the Provençal the guage of heretics, and forbade its use by dents. The inhabitants of the south of nce not only found themselves forced to mit to a yoke which they hated, but beheld ir literature overshadowed by that of the rth. From 1250 to 1290 only a few trouba- re of any eminence flourished, and in the h century Provençal poetry can hardly be d to have existed in the country of its ori- . The language, moreover, passed into a lect, which, with various modifications and rations, still lives among the peasantry. But parts of Spain it continued to be cultivated h success for many years. During the 12th l 13th centuries, the literature and literary on of Catalonia were the same as the Pro- çal, and the list of troubadours is enriched h the names of Catalan nobles and kings Aragon. Long after the genuine race of vençal poets had passed away, Provençal try was carried to a high degree of perfec- n by the inhabitants of Valencia. When the sade against the Albigenses drove the trou- dours from their homes, many sought refuge the court of Aragon, and gave to Saragossa l Barcelona the attractions once belonging Arles and Marseilles. But even there it did long survive. At the beginning of the 14th tury it had ceased to exist in Castile, and ward the close of that century was displaced n Catalonia and Aragon, or rather corrupted the idiom of those countries. It did not , however, without a struggle. In 1323 an empt was made to revive it by the magis- cy of Toulouse, who formed a guild in that y under the name of the "Very Gay Com- ny of the Seven Troubadours of Toulouse," l in 1355 established a body of laws under title of "Ordinances of the Seven Lords nservators of the Gay Science," which laws ulated for centuries afterward the floral mes celebrated in that city on the first of y. At the request of John I. of Aragon two the conservators of Toulouse went in 1390 Barcelona, and established there a consistory the gay science, which was afterward re- ved to Tortosa. This institution attained to nsiderable renown in the following century, en for a period the Provençal poetry, modi- l by the ruder but more vigorous idiom of talonia, held sway. But the Provençal ally disappeared as the language of the high- classes, though it still lives in the rustic dia- ts of Catalonia and Valencia. In Italy it o gave way to the Tuscan idiom, enriched by genius of Dante, and was forgotten in the vival of the ancient literature which in that ntry early absorbed the attention of all n of genius. Still, in spite of the overshad- ving influence of other tongues, the Provençal continued to be, at least in the south of France, until the present time, a medium of poetic composition, and some of those using it have acquired celebrity. Of these the most famous is Jasmin of Agen. (See *Jasmin*.)—The earliest writers on the Provençal literature were Cardinal Bembo and Jean de Nostre Dame, or Nostradamus, brother of the astrologer. Nostre Dame collected a large number of manuscripts, and composed a work on the lives and writings of the old Provençal poets. But the language was especially indebted to Lacurne de Sainte-Palaye, who expended a vast amount of time and labor in ransacking the libraries of France and Italy, and collecting materials on the subject. At the time of his death, however, the lexicon undertaken by him had not been completed, and the mass of matter collected had not been digested or published. It is chiefly to M. Raynouard, a native of Provence, that we are indebted for our knowledge of the Provençal. In his *Choix des poésies originales des troubadours* (6 vols., Paris, 1816–'21), he published vestiges of their early poetry, and lives and extracts from the writings of about 350 poets. Previously he had written a grammar of the language (Paris, 1816); and to this he added a lexicon which appeared after his death (6 vols., Paris, 1836–'45). In his footsteps followed Charles Claude Fauriel, whose *Histoire de la poésie Provençale* (3 vols. 8vo., Paris, 1846), delivered in a series of lectures as professor in the faculty of letters at Paris, is the most elaborate work on the subject upon which it treats. Since the labors of Raynouard and Fauriel, numerous works and essays have been written upon the poetry of the troubadours in France, and in Germany and Italy it has also received considerable attention. No original treatise upon the subject has yet appeared in English. A translation by G. J. Adler of a little more than one half of Fauriel's work was published at New York in 1860.

PROVENCE, an ancient province in the S. E. of France, bounded N. by Dauphiné and Venaissin, E. by the Alps, S. by the Mediterranean, and W. by Languedoc. Capital, Aix. It was divided into Upper and Lower Provence, watered by the Rhone, Durance, Sorgues, Argens, Arc, Verdon, and Var, and celebrated for its delightful climate and rich fruits, though the soil is somewhat arid. It now forms the departments of Basses-Alpes, Bouches-du-Rhône, and Var, and a part of those of Vaucluse and Drome.—Provence was for a long time the only territory to which the Romans gave the name of *provincia*. It passed into the hands of the Visigoths in the 5th century, and of the Ostrogoths in the 6th, and, after being for a while in the possession of Austrasia, fell to Lothaire on the division of the empire of Charlemagne. In the 10th century it formed part of the kingdom of Arles, which was subsequently united to the kingdom of Germany; but Provence meanwhile was governed by virtually independent counts, who about 1063 became hereditary. The last count bequeathed it to King Louis XI. in 1481, and it was thereafter an integral part of the French monarchy.

PROVERB, a short, pithy saying, which embodies some well known truth, and is often indeed a truism, but acquires significance by its application. Erasmus defines it as "a well known saying remarkable for some elegant novelty;" Cervantes as "a short sentence drawn from long experience;" and Lord John Russell as "the wit of one and the wisdom of many." Proverbs are perhaps as old as any writing of which we have knowledge. Hesiod preserved a good many, and Erasmus pointed out the sources of some in the responses of oracles, the verses of poets, and the allegorical symbols of Pythagoras. The familiar adage: "Evil communications corrupt good manners," was quoted by St. Paul, and is found in a fragment of the comic poet Menander. Cicero made frequent use of proverbs from the Greek. Aristotle, struck by the condensed wisdom of proverbial sayings, supposed them to be the wrecks of an ancient philosophy saved from the ruin in which the rest of the system had been lost by their elegance and shortness. The speech of Odin in the "Edda" contains many which are very characteristic of the life of the ancient Scandinavians; and the Spaniards attribute to their "sayings of old wives by the fireside" a greater antiquity than they claim for any written document in their language. The proverb is so nearly allied to the motto, symbol, device, sentence, apologue, and fable, that it is not always easy to draw the line of distinction. Howell describes the ingredients of a good proverb to be "sense, shortness, and salt;" and George Herbert pithily indicated its brevity and deep meaning when he spoke of it as "a dart" (*jaculum*). Bacon remarks that "the genius, wit, and spirit of a nation are discovered in its proverbs." Those of Spain are in advance of those of any other country in point of number, originality, and elegance. Many of the tritest and seemingly most national Scotch and English proverbs have been borrowed from the East; and even the famous old saw, "to carry coals to Newcastle," has a prototype not only in the Persian saying, "to carry pepper to Hindostan," but also in the Hebrew, "to carry oil to the city of Olives."—Collections of proverbs have been made from very ancient times. Zenobius and Diogenianus in the 2d century gathered, the former 552, and the latter 775. Polydore Vergil published a volume of *Adagia* in 1488, and Erasmus another soon afterward containing about 5,000. Michael Apostolius of Byzantium left a collection of 2,000 ancient proverbs, which were printed at Leyden in 1653. There are Spanish collections by Mendoza, marquis of Santillana (1508); Pedro Valles (1549); Hernan Nuñez de Guzman (1555); Mal Lara (1568), under the title of *La filosofia vulgar;* Oudin (Paris, 1608); and Cejudo (1695), with corresponding Latin adages. Juan de Yriarte afterward gathered about
24,000, and there is another collection b
pulles in 6 volumes. Florio gives 6,0
ian proverbs in his *Giardino di ric*
(1591); and there are similar works by
sini (1604) and Varini (*Scuola del vulg*
Oudin published a collection of Frenc
erbs under the title of *Curiosités Fr*
and Fleury de Bellingen an *Explica*
proverbes François. There is a Danish
tion with a French translation (Cope
1757); Sailer published in German "T
dom of the Streets, or the Meaning a
of German Proverbs" (Augsburg, 181
John Ray prepared in 1670 a collec
proverbs in various languages, comprisin
lish, Scottish, Welsh, Irish, Danish,
and Hebrew, which has been repri
Bohn's "Antiquarian Library" under th
of "A Handbook of Proverbs." There
polyglot collection by Dr. J. Mapleto
lished anonymously in 1707. Among
English collectors are Camden, Herbert
Prudentum, 1640), Howell, Codrington
and Clark; and Burckhardt prepared "
Proverbs, or the Manners and Custom
Modern Egyptians," illustrated from the
verbial sayings (London, 1830).

PROVERBS, a book of the Old Tes
entitled in the Hebrew original as well
Septuagint and the Vulgate "The Prove
Solomon." This, however, by no mea
cribes the real or final authorship of the
to Solomon, for it is expressly stated in
xxv. that the latter part of the book, be
with that chapter, was written and ad
the previous portion by order of King
kiah. It has, moreover, always been cons
doubtful whether Solomon ever made an
lection of his proverbs in writing. Bu
hardly ever been contested that a large
in the composition of the book may be as
to the wise king, who is said (1 Kings iv
to have uttered 3,000 proverbs, and wh
so celebrated all over the eastern world f
wisdom. The ancient writers of the G
churches frequently gave to this book
name *Sophia* (wisdom).—As regards its
tents, the book is divided into several p
which are distinguished from each othe
separate headings. The first 7 verses o
first chapter may be regarded as a headi
the entire book. Then begins the firs
closing with the end of the 9th chapter.
part does not contain a collection of pro
proper, but rather a series of connected a
nitions in a sententious form. They inc
the love of wisdom, and describe the gl
reward of wisdom and the pernicious c
quences of wickedness. The 2d part, w
extends from chap. x. to xxii. 16, contain
main collection of proverbs and the chief p
of the entire book. The proverbs, about
in number, contain moral precepts and r
of life for every age and every class of me
a clear, sententious form. Generally one p
erb is comprised in one short verse, of 2 me

s or clauses, and 6 or 7 words or phrases.
e 2 members form a parallel opposition to
h other, which is generally carried out even
the single expressions; as for example (x. 1):

A wise son maketh a glad father:
ut a foolish son is the heaviness of his mother.

e grouping together of the proverbs in this
rt appears to have been accidental, except
t occasionally 2 or 3 verses follow each
er which have a characteristic expression in
mmon. With chapter xxii. verse 17, a kind
appendix begins, introduced by a separate
ading. The proverbs of this section gener-
y consist of 2 verses, and sometimes of 3;
y are constructed with less regularity, some-
es containing more than 2 members, and
en without any parallelism. Sometimes
overbs of kindred contents are grouped to-
her. A second appendix to the first collec-
n begins at chapter xxiv. verse 23, and is
arated from the preceding by the heading:
These also are from wise men" (in the com-
n English version: "These things also be-
g to the wise").—The second main collec-
n begins with chapter xxv., which is headed:
These are also proverbs of Solomon, which
men of Hezekiah, king of Judah, copied
t." The proverbs, as in the first collection,
sist generally of one verse each, and each
se of 2 members with parallel opposition.
t exceptions to this rule occur more fre-
ntly than in the first collection. With re-
d to their contents, the proverbs of the sec-
d collection are not so plain and intelligible
those of the first, but more artificial and fre-
ntly even enigmatical. This collection ex-
ds over 5 chapters, and is again followed in
2 last chapters of the book by 3 different
endices.—It is impossible to decide whether
compilation and arrangement of the entire
k were made at one time by one man, or
ether the addition of the several parts took
e at different periods. The advocates of
former opinion adduce in their favor, that
arrangement of the whole seems to rest on
ell conceived and thoroughly executed plan.
either case it is considered probable that the
k received its present form between the time
the death of King Hezekiah and the end of
7th century B. C.—We have valuable com-
ntaries on this book by Salazar (1641),
ultens (1748), Hodgson (1788), Lawson
21), Umbreit (1826), Ewald (in vol. iv. of
Poetische Bücher des Alten Testaments),
ndlaw (2 vols., 1860-'61), and others. Ger-
n translations are added to the commenta-
s of Umbreit and Ewald; a new English
nslation, with Ecclesiastes and Canticles,
been published by the Rev. G. R. Noyes,
D. (Boston, 1846).

ROVIDENCE, a N. co. of R. I., bordered
and E. by Massachusetts and W. by Con-
ticut, and drained by the Blackstone river,
ich runs partly along the E. border, and
Pawtucket, which forms a portion of the S.
ndary; area, 380 sq. m.; pop. in 1860,
107,799. It has an uneven surface and generally fertile soil. The manufacturing interest is very large, and in 1850 there were 99 cotton and 18 woollen factories, and 8 calico printing mills, beside a large number and variety of others. The agricultural productions were 137,070 bushels of Indian corn, 308,879 of potatoes, 10,242 of rye, 32,205 tons of hay, 18,700 lbs. of wool, and 476,843 of butter. There were 13 grist mills, 38 sawing and planing mills, 11 newspaper offices, 101 churches, and 13,370 pupils attending public schools. It is intersected by the Hartford and Providence and Providence and Worcester railroads. Capital, Providence.

PROVIDENCE, a city, the principal port of entry, and semi-capital of Rhode Island, situated at the head of navigation on an arm of Narraganset bay known as Providence river, 35 m. from the ocean, 43 m. S. S. W. from Boston, 173 m. E. from New York, and 396 m. N. W. from Washington; lat. 41° 49′ 22″ N., long. 71° 24′ 48″ W.; pop. in 1730, 3,916; in 1774, 4,321; in 1790, 6,380; in 1800, 7,614; in 1820, 11,745; in 1830, 16,836; in 1840, 23,172; in 1850, 41,513; in 1860, 50,666. In population and wealth Providence is the second city in New England. It covers about 9 sq. m., and is built on both sides of Providence river, which is here crossed by two bridges, one of which is 140 feet in width. Above this, and within the centre of the city, the river expands into a beautiful cove nearly a mile in circuit, along which is built a wall surmounted by an iron railing. A park planted with elms, with gravelled walks, surrounds the cove. Two small streams enter on the N., the Moshassuck and the Woonasquatucket rivers, upon which are many machine shops and manufactories. The land on which the city stands is very irregular. On the E. side a hill rises to the height of 204 feet above tide water. On the W. it is level, with little elevation for a quarter of a mile, when the land rises to the height of 75 feet. The hill sides, even to their summit, are covered with dwelling houses, interspersed with gardens and ornamented with trees. The larger portion of the dwelling houses in the city are of wood; the remainder are of brick and stone, among which are many mansions of great elegance.—There are 3 daily newspapers printed in the city, from which are also issued semi-weekly and weekly papers in addition to 3 others. The first printing press was established here by William Goddard in 1762, from which office the "Providence Gazette" was issued. There are 53 churches, viz.: 14 Baptist, 6 Congregational, 6 Episcopal, 7 Methodist, 1 Moravian, 1 New Jerusalem, 1 Presbyterian, 6 Roman Catholic, 2 Seamen's Bethels, 1 Second Advent, 1 Sons of Israel, 1 Spiritualist, 4 Unitarian, and 2 Universalist. Several of these, built of stone and brick, present fine specimens of architecture. The first Baptist church, which is the oldest in America, was founded here in 1638. Butler hospital for the insane, incorporated in 1844, is situated on the W. bank of Seekonk river, surrounded by extensive grounds, 60 acres of which are under cultivation, with about the same extent of native woodland. The average number of patients is about 150. The edifice was erected and the lands purchased by subscription, Cyrus Butler contributing $40,000, and Nicholas Brown $30,000. Its annual disbursements are about $30,000. The state of Rhode Island makes an annual appropriation of $1,500 to enable the governor to aid poor insane persons there, and it also pays a portion of the expenses of all such poor insane as the town may choose to send. The minimum price of board for patients is $3 per week. Dexter asylum for the poor is situated on the highest land E. of the river. It is a fine edifice of brick, 170 feet long, including wings, and 3 stories high. The grounds, which comprise about 40 acres, are enclosed with a stone wall 10 feet high. The land was given by Knight Dexter, and the buildings erected by the city. The reform school, established in 1850, for juvenile offenders between the ages of 8 and 18, is in the S. W. part of the city. The number of inmates at its last annual report, 1860, was 187, of whom 139 were boys and 48 girls. Its expenses for the year were $14,941.77. The state prison is on the N. side of the cove. At the close of the year 1860 it contained 67 convicts. The county gaol is within the prison walls. The total income of the prison and gaol for 1860 was $16,072.29; total expenses, $13,489. The convicts are almost exclusively employed in cabinet work and shoemaking. Beside these, there are 35 other benevolent and disciplinary institutions.—First in the department of education is Brown university, which in 1860 had 2,043 alumni, of whom 1,256 are now living, and 232 students. A subscription is now (1861) in progress for the erection of a new library building and a laboratory. (See BROWN UNIVERSITY.) The Athenæum, incorporated in 1836, is a handsome granite building. It has a reading room, and a well selected library of 25,601 volumes (June 1, 1861), to which large additions are annually made. The Friends' yearly meeting boarding school, or "Quaker college," occupies a lot of 43 acres in the easterly part of the city. It consists of two spacious brick buildings, 3 stories high with wings of 2 stories. It is liberally endowed and in a prosperous condition. A legacy of $100,000 was bequeathed to it by the late Obadiah Brown. The average number of pupils is about 180, equally divided between boys and girls. The Roman Catholics have two flourishing institutions for educational and charitable purposes. The number of books in the public libraries in the city is 84,930; in Sabbath school libraries, 26,200; in private libraries, 213,725. The schools comprise 4 grades, viz., the high school, grammar, intermediate, and primary schools. The first has an average of 300 pupils with 8 teachers. The 7 grammar schools have 2,050 pupils and 43 teachers. There are 18 in[illegible] diate schools with 38 teachers and 1,9[illegible] and 22 primary schools with 48 teacher[illegible] 8,200 pupils. The whole number admi[illegible] the various public schools during the [illegible] 1860 was 7,852. The cost of this establi[illegible] for the last year was $81,369.04, of wh[illegible] city paid $65,812.97 and the state $10,6[illegible] received from registry tax, $4,955.36. [illegible] Rhode Island historical society, found[illegible] 1822, occupies a fine brick and granite b[illegible] ing opposite the university grounds, erec[illegible] 1844. It contains, beside a valuable libr[illegible] large collection of manuscripts and other [illegible] morials relating to the history of the state [illegible] has published 5 volumes of historical c[illegible] tions.—The arcade, on the W. side, is the [illegible] of the kind in the United States. It ex[illegible] from Westminster to Weybosset street, [illegible] feet in length by 80 in width, a portion [illegible] centre being about 50 feet wider; it is [illegible] high, has 82 shops, and is devoted chi[illegible] the retail trade, dry goods, boots and [illegible] hats, and jewelry being the principal ar[illegible] sold. The building is of granite, with t[illegible] posing Doric porticos, one on each stre[illegible] columns of the porticos are of single blo[illegible] granite. The city has 38 banks, with an [illegible] gate capital on Jan. 1, 1861, of $15,5[illegible] circulation, $2,150,959.75; deposits, $[illegible] 806.68; loans, $19,901,828. There are [illegible] stitutions for savings, which at the c[illegible] 1860 held in deposit $5,011,387, belong[illegible] 19,892 depositors. There are 18 ins[illegible] companies, including stock and mutual co[illegible] nies, and 39 agencies of companies, 37 of [illegible] are from other states and foreign cou[illegible] The railroads terminating at Providence [illegible] the Boston and Providence; Stonington [illegible] Providence (lately extended to Groton); H[illegible] ford, Providence, and Fishkill; Prov[illegible] and Worcester; Providence, Warren, and B[illegible] tol; and Newport and Fall River, now in p[illegible] ress of construction. All the railroads oc[illegible] the same passenger depot, a spacious and [illegible] gant structure of brick nearly 700 feet long[illegible] ated near the heart of the city on the sou[illegible] side of the cove, and near the great bridge [illegible] connects the two portions of the city. Sev[illegible] steamboats ply between Providence and var[illegible] places on Narraganset bay, including Bri[illegible] Newport, Fall River, and Warwick.—[illegible] manufactures of Providence are very exten[illegible] and include cotton, wool, iron, gold, and [illegible] The number of individuals, companies, and [illegible] porations engaged in manufactures to the ex[illegible] tent of $500 or over annually is 596; ca[illegible] employed, $8,426,735; value of raw mat[illegible] used, $7,994,071; value of annual prod[illegible] $17,415,849. There are 6 cotton mi[illegible] woollen mills, 26 iron works, and 7 blea[illegible] and calendering establishments. Among [illegible] manufactories of iron are 8 of screws, all [illegible] ed by the American screw company, which [illegible] a capital of $1,070,000. They use 5,000 t[illegible] of iron a year, of which 4,500 tons are [illegible] rews, the remainder for wire. They make n an average 15,000 gross of screws each day, r 4,620,000 gross a year, and at one of the es- blishments 1,000 gross in an hour, consum- g 3,000 tons of coal a year, and employing om 700 to 1,000 hands. The manufacture of ld and silver ware was commenced in Provi- nce more than a century ago, and now rivals extent and magnitude that of any other lace in the country. A large manufactory as established in 1805. There are 96 estab- lishments in the city for the manufacture of welry. Those for silver are few but large, ne of them manufacturing $500,000 worth an- ually. The number of persons employed is om 1,600 to 2,000, and the annual product ot less than $3,000,000. The city contains 8 factory operatives beside those engaged in e works already mentioned, 952 carpenters, 2 machinists, 364 masons, 305 moulders, 206 acksmiths, 202 boot and shoe makers, 69 cigar akers, 70 cabinet makers, 246 painters and aziers, 96 engravers, 84 engineers, 68 harness akers, 102 printers, 183 weavers, and 224 ilors. The two calico printing establishments roduce annually 1,060,000 pieces or 36,244,000 ards, valued at $2,771,000. In the vicinity f Providence are other print works owned ere, which produce 60,000 pieces of goods a eek. There are 18 furnaces employed in sting machinery, stoves, ploughs, &c., and 10 ops for engraving copper rollers for printing licoes. For the motive power to perform all e work mentioned, there are employed 96 eam engines, with horse power ranging from to 400 each. The aggregate horse power of l these engines is 4,697, used by 227 different stablishments, and employing 8,045 persons. eside these many caloric engines are in use. —During the 6 years from 1856 to 1861 much ttention has been given to vital statistics in rovidence, and the returns of births, mar- ages, and deaths are probably more complete nd perfect at the present time than those of ny other city in America. During the same me special efforts have been made for the revention of disease by sanitary measures. In ddition to this there are some peculiarities f natural location and internal construction hich make the city very healthy. During e year 1860, with a population of 50,666, ere were 1,001 deaths, 523 marriages, and ,648 births; or one birth in 30.74, one person arried in 40.02, and one death in 50,61 of e population. The annual average for 6 ears, 1855 to 1860 inclusive, was one birth in 9.85, one person married in 39.60, and one eath in 50.22 of the population. The colored opulation of Providence shows no increase in e last 20 years. The present number is about ,500.—The valuation of property and taxation Providence for a few years past have been as llows. In 1846: real, $14,676,900; personal, 10,916,300; total, $25,593,200; amount of x, $102,372.80, or 40 cts. on $100. In 1850; al, $17,659,700; personal, $14,126,000; total, $31,959,000; tax, $160,385.85, or 52 cts. on $100. In 1854: real, $33,598,600; personal, $15,330,100; total, $48,928,700; tax, $274,000.72, or 56 cts. on $100. In 1856: real, $36,188,097; personal, $20,108,200; total, $56,296,297; tax, $380,000, or 67½ cts. on $100. In 1860: real, $37,089,800; personal, $21,028,500; total, $58,118,300; tax, $325,462, or 56 cts. on $100. The value of literary, church, and city property not taxed in 1860 was $3,075,228. This valuation is only for property in the city, and does not represent the wealth of the citizens, which may fairly be estimated at $80,000,000, in addition to public property, and property devoted to religious and educational purposes.—During the colonial period of the state, Providence as well as Newport enjoyed an extensive foreign commerce, which has now greatly fallen off, and its commerce is chiefly confined to the coasting trade. The number of vessels which arrived from foreign ports for the year ending Dec. 31, 1860, was 128, tonnage 24,457; number cleared, 111, tonnage 20,267; total number of vessels arrived coastwise, 5,035. The chief articles imported were coal, ivory, dates, gum copal, pig and bar iron, molasses, raw hides and skins, cloves, pepper, lumber, and salt. The chief articles received coastwise were: coal, 342,411 tons; flour, 277,161 barrels; grain, chiefly corn and wheat, 3,387,541 bushels; cotton, 110,846 bales; hay, 2,014 tons; and lumber. The total value of merchandise imported was $375,555. The tonnage of vessels belonging to the district is 19,570.—The city is divided into 7 wards, and is governed by a mayor, 7 aldermen, and 28 common councilmen, elected annually.—Providence was first settled in 1636, by Roger Williams, who was banished from Massachusetts on account of his religious opinions, and who, in his new colony, was the first to propose and establish the principles of universal freedom in religious matters. The rock on the banks of the Seekonk river on which he landed, and where he was received by the Indians, is about a mile from the centre of the city. The town received its first patent from Charles I., bearing date 1643. It suffered much in the famous war of King Philip, in 1675, when a considerable portion of it was burned. It again suffered severely in Sept. 1815, when a south-easterly storm forced an extraordinary tide into the harbor, raising the water 12 feet higher than the usual spring tides, spreading devastation and ruin along the wharfs and the lower part of the town, overturning houses and stores, and doing much damage to the shipping. One large East Indiaman was driven up beyond the cove, from which she could never be removed. Providence received a city charter in 1832.

PROVINCE (Lat. *provincia*), under the ancient Roman state, a territory beyond Italy which had a regular organization under Roman officers. After Rome had extended her conquests beyond the peninsula, the government was divided between Italy and the provinces. The first province was Sicily (241 B. C.), and the second Sardinia (235 B. C.). In Cæsar's time Gallia Ulterior was called simply *Provincia*, whence the more modern Provence, which was included in this region. The mode of settling the government of a conquered country was not uniform; the organization was effected by the military commander, either alone or with the assistance of a commission of senators. The chief administrative officer was at first a prætor, afterward a proprætor; and in the later times of the republic a consul, after completing his term of office at Rome, was appointed to the government of a province with the title of proconsul. His term of office was one year, but it was frequently prolonged. The emperor Augustus made considerable changes in this system, taking upon himself the charge of those provinces where a large military force was required, and committing the rest to the care of the senate and people of Rome; whence originated the distinction, preserved until the 3d century, between the *provinciæ propriæ populi Romani* and the *provinciæ propriæ Cæsaris*. Of the former two were given to the *consulares*, and the rest to those who had filled the office of prætor, and the title of the governor was proconsul or *præses*. The governors of the imperial provinces were styled *legati Cæsaris*, and held office at the emperor's pleasure. Justice was administered according to the laws of the country, to such Roman laws as were specially enacted for the provinces, and to imperial constitutions, particular edicts, and *senatus consulta*, except when, as sometimes happened, the Roman laws were extended to the provinces. A part of the land was confiscated, and sometimes granted on lease to the original possessors. The public revenues were farmed by *publicani*. The governor received no salary, but his position gave him abundant opportunities for extortion, and he also drew from the Roman treasury a sum of money for certain necessary expenses. He alone, as a general rule, enjoyed that high authority denoted by the term *jurisdictio*, which included the right to put persons in possession of property, to nominate guardians for minors, and to appoint judges. All inferior officers acted as his deputies, and this constituted the chief difference between provincial towns and the Italian colonies, as the latter possessed free municipal constitutions, chose their own magistrates, and made their own laws. A grant of the *jus Italicum* to a provincial town placed it upon nearly the same footing as the colonies of the peninsula. With the growth of the imperial power, however, these distinctions were abolished, and the Italian cities lost the most important of their peculiar privileges and were gradually reduced to the condition of the provinces.

PROVINCETOWN, a township and village of Barnstable co., Mass., on the extremity of Cape Cod, 50 m. S. E. from Boston; pop. in 1860, 3,300. It has an excellent harb sufficient depth for the largest vessels. Th habitants are supported chiefly by the fis In 1860 there were 80 vessels with 6 engaged in the whale fishery, and 110 v with 1,100 men in the mackerel and co eries. There were 4 churches (1 Con tional, 2 Methodist, and 1 Universalist), a weekly newspaper.

PROVOOST, **Samuel**, D.D., bishop of Protestant Episcopal church in New Yor in the city of New York, March 11, 174 Sept. 6, 1815. He was graduated at K (now Columbia) college in 1758, went t land in 1761, entered as fellow commo St. Peter's college, Cambridge, and w dained deacon in Feb. 1766, by the bish London, and priest in March, 1766, b bishop of Chester. Having returned to York, he became assistant minister of T church in Dec. 1766. Two years later, in sequence partly of religious and partly o litical differences, he dissolved his conn with Trinity church, and in 1770 retire small farm in Dutchess co., where he re till the close of the revolution, occupying self chiefly in literary and scientific pur Directly after the war the new vestr Trinity church elected him as rector. post he held for nearly 17 years. He chaplain to the continental congress in and to the senate of the United States in and he received the degree of D.D. fro university of Pennsylvania in 1786. H been elected bishop of New York in 1786, he accompanied Dr. William Wh England, and was consecrated with him. 4, 1787, at Lambeth palace, the archbish Canterbury presiding. Bishop Provoo signed on account of his health, in Sept. the rectorship of Trinity church, and in 1801, the episcopal office. The latter re tion, however, was not accepted by the of bishops, and Dr. Benjamin Moore was c to be his coadjutor.

PROVOST (Lat. *præpositus*, placed be Fr. *prévôt*), in Scotland, the chief muni officer of corporate towns, with the same tions as the mayor of English cities; an England the title of the heads of certain leges.—**Provost Marshal** is the title of a tary officer who takes cognizance of o against discipline, and inflicts summary ishment on offenders; and in the navy, o who has the custody of prisoners at a martial, and till the execution of the sent of the court.

PRUDENTIUS, **Aurelius Clemens**, a L Christian poet, born in Spain in 348. He w lawyer, became a civil and criminal judge was appointed to a high military station at c In his later years he devoted himself to reli exercises and study. His extant poems *Præfatio*, written when he was 57 years and giving a catalogue of his works up to time, with a brief and indefinite autobiograp ems, which every thing known in regard to his fe has been learned; *Cathemerinon Liber*, 12 cred hymns, some of which have been inserted in the liturgy of the Roman Catholic church; *potheosis*, maintaining the divinity of Christ, nd the orthodox doctrine of the Trinity; *amartigenia*, on the origin of sin, directed gainst the Marcionites; *Psychomachia*, representing the struggle between virtue and vice in e soul, and the triumph of the former; *Cona Symmachum Liber I.*, an account of the nversion of Rome, with an exposure of the lly of the ancient religion; *Contra Symmahum Liber II.*, a refutation of the argument of ymmachus in his petition to the emperor Valennian; *Peristephanon Liber*, 14 poems in honor f martyred saints; *Diptychon* or *Dittochaeon*, 8 poems in heroic hexameters, 24 describing emarkable events and characters in the Old estament, and 24 describing similar circumances and events in the New, about the uthenticity of which there has been much ontroversy. The only other poem extant is e *Epilogus*. Bentley called Prudentius "the omer and Virgil of the Christians." The arliest dated edition of his works is that of eventer (1472); the best is that of Faustino revalo (2 vols. 4to., Rome, 1788-'9).

PRUD'HON, Pierre Paul, a French painter, orn in Cluny, April 6, 1760, died in Paris, eb. 16, 1823. The 13th son of a mason, who ied while he was a child, he was educated by harity at the convent of his native town, where is taste for art was aroused by the paintings n the chapel; and being recommended to the ishop of Mâcon by his teachers, he was placed y him under the tuition of Devosges, a meritoious artist of Dijon. The young man, having won a prize awarded by the states of Burgundy, went to Rome, where, while studying Raphael, Leonardo da Vinci, and above all Correggio, he ntered into the most friendly relations with he sculptor Canova. In 1789 he returned to rance, where he underwent a long struggle with poverty, and supported himself by occaionally painting miniatures, and making drawngs for concert tickets, bill heads, tradesmen's ards, and confectionery boxes. During the amine of 1794 he paid a visit to Rigny, near Gray, and there executed a series of pastel ortraits for which he received a handsome rice. On his return to Paris he won a prize or an allegorical drawing, representing "Truth escending from Heaven, led by Wisdom." In 1805 he painted on a ceiling in the museum of the Louvre, "Diana imploring Jupiter;" and oon after received from Frochot, then prefect of the Seine, an order for a great picture to adorn the hall of the criminal court: "Justice and Divine Vengeance pursuing Crime." For this masterpiece, which was exhibited in 1808, he received from Napoleon in person the cross of the legion of honor. He was appointed teacher to the empress Maria Louisa, painted the portrait of her child, became a member of the Institute, and had apartments in the Sorbonne. The "Zephyr balancing himself upon the Water," "Innocence seduced by Love," and "Venus and Adonis" belong to this period. In 1819 he exhibited a painting of the Assumption. Two years later his friend and pupil Mlle. Mayer, for whom he entertained a warm affection, put an end to her life, and thenceforth he pined away under the weight of despondency and sorrow. He nevertheless completed "The Indigent Family," the rough draught of which had been left by his unfortunate pupil, and "Christ dying upon the Cross," which was exhibited after his death. His illustrations of *Daphnis et Chloé* and Tasso's *Aminta* are highly valued by artists.

PRUNE. See Plum.

PRUNING, the cutting off superfluous branches from trees, vines, &c., in order to increase their fruitfulness. The practice has also been advantageously extended to shortening the roots of fruit trees, the effect being to check the too rapid growth of the leaves and branches, and divert the nutritious matter in the sap to the production of fruit. In England, on account of the system of training fruit trees to walls, which the peculiarities of the climate render almost necessary for their successful cultivation, the art of pruning has received much more attention, and is carried to far greater perfection, than it demands under the clearer sky of the United States, where fruit trees are cultivated without difficulty as "standards" or in open orchards. Still, when judiciously practised here, unthrifty trees in the nursery and enfeebled orchard trees, by the removal of their weak and crowded branches and of those in the interior of the tree out of the reach of the sun and air, may often be entirely regenerated and restored to the condition of good bearers. But for healthy trees the practice is often worse than useless. The growth of trees is promoted by the supply of sap carried up the inner bark. If this by any reason becomes incompetent to furnish the quantity required for all the branches, and the whole tree consequently languishes, the removal of part of these allows the remaining limbs to receive all the sap, and to assume a rapid and healthy growth. By this healthy action the bark itself is invigorated and the whole tree is benefited. The proper time for this pruning is after the fall of the leaf in the autumn, or during mild days in the winter, provided it be not in a region of very severe winters, as to the N. of lat. 43° N. There it should be deferred till the end of February, but not till the buds begin to swell and the sap to flow. Downing recommends for pruning fruit trees a fortnight before midsummer as by far the best season in the northern and middle states. Wounds made at that time rapidly heal over; and it is the best time for judging of the shape of the tree, and how most easily to improve it. A solution of gum shellac in alcohol is the best composition to apply to the surfaces laid bare in removing large limbs. The fruitfulness of peaches, nectarines, and apricots is increased by the system of pruning called "shortening-in" and "spurring-in," which consists in reducing the young wood by cutting off the small branches and forcing the sap to accumulate in the remainder and thus cause the formation of many bearing shoots. This method Downing regards as especially important for peach trees after they come to bearing, and to the neglect of it he ascribes the fact of the rapid deterioration of peach trees in the United States. It should be done toward the end of February or not much later, and extend to the removal of half the growth (equal to 6 to 12 inches) of the last year over the whole outside of the head of the tree, and also upon the inner branches. For grapes a different and much more thorough system of pruning is advisable, founded on the facts that the vine bears well only when it is young or composed mainly of young wood, and that the shortening or spurring-in method practised with foreign grapes is soon followed by mildew. The best mode is that known as the long or renewal mode, which consists in laying down every year long shoots of the previous year's growth, and as these come to bearing removing entirely the old vine. The branches which form in one year are trained for bearing the next year; and after this they are cut down to the main branch from which they sprung, others in the mean time having come forward to take their place. By judicious pruning and training the vines are kept back so as to produce a moderate amount of fruit the 3d year, and increasing quantities the 4th and 5th years.—Root pruning consists in digging a trench early in November about 18 inches deep around the tree and cutting off the principal roots with a sharp spade. Manure is introduced into the trench, and the trees may thus be made to flourish almost as well in a naturally poor as in a good soil. By this method dwarfed trees may be made plentiful bearers, growing within 6 feet of each other, and the trees, though 15 or 20 years old, may be conveniently taken up at any time and removed to other places. The pruning may be renewed every year, though a cessation for one, two, or three seasons may sometimes be advisable, that the tree may not be too much exhausted.

PRUSA, or PRUSIAS. See BROUSSA.

PRUSSIA (Ger. *Preussen*), one of the six great powers of Europe, consisting of a large portion of northern Germany, the former duchy of Prussia, and part of the former kingdom of Poland. The name was applied until the 18th century only to the former duchy of Prussia on the Baltic and the Vistula, whose inhabitants, a Lithuanian tribe (Porussi, or Borussi, whence the Latin name of the country, Borussia), had been conquered by the Teutonic knights in the 13th century. The rulers of Prussia were formerly styled kings in Prussia, thus expressing that their German possessions were no kingdom; but Frederic the Great, having firmly established his power, assumed the title of king of Prussia. Since then the different provinces ruled over by the Hohenzollern dynasty have come to be considered a consolidated kingdom.—The kingdom of Prussia consists of two distinct territories, beside a few small possessions, wholly enclosed within the territory of neighboring states. The eastern territory, covering an area of 89,287 sq. m., lies between lat. 49° 50′ and 55° 50′ N., and long. 9° 50′ and 22° 50′ E., and includes 6 of the 8 provinces of the kingdom, viz.: Prussia proper, Posen (wrested from Poland), Brandenburg (the original possession in Germany of the Prussian dynasty), Pomerania (partly inherited and partly conquered from Sweden), Silesia (wrested from Austria), and Saxony (partly wrested from the kingdom of Saxony). This territory is bounded N. by the Baltic sea, E. by Russia, S. by Austria, the kingdom of Saxony, and the Saxon duchies, and W. by Hesse-Cassel, Hanover, Brunswick, and Mecklenburg. The western territory, consisting of Westphalia and the Rhenish province, 10,305 sq. m., extends from lat. 49° 10′ to 52° 30′ N., and from long. 5° 50′ to 9° 25′ E., and is bounded N. by the Netherlands and Hanover, E. and S. E. by the principalities of Schaumburg and Lippe, Hanover, Brunswick, Hesse-Cassel, Hesse-Darmstadt, Waldeck, and Nassau, S. by the Palatinate, Hesse-Homburg, and France, and W. by Luxemburg, Belgium, and the Netherlands. A third distinct Prussian territory, consisting of the formerly independent principalities of Hohenzollern (ceded to Prussia in 1850), is enclosed by the kingdom of Würtemberg and the grand duchy of Baden. The entire area of the kingdom is somewhat less than that of the New England states and New York combined; but while these in 1860 had only 7,000,000 inhabitants, Prussia had, by the latest census (1858), 17,740,000, or 164 to the square mile, distributed as follows:

Provinces.	Area in sq. m.	Population.	Proportion to sq. m.
Prussia proper..........	24,926	2,744,500	110
Posen..................	11,262	1,417,155	125
Brandenburg............	15,468	[illegible]	150
Pomerania..............	12,146	[illegible]	109
Silesia................	15,700	3,269,613	208
Saxony.................	9,734	1,910,983	196
Westphalia.............	7,787	1,566,441	201
Rhenish province.......	10,305	3,106,672	301
Hohenzollern...........	440	64,235	146
Jahde navy yard (purchased from Oldenburg in 1854)........	....	800	..
Total............	107,963	17,739,913	164

Of the total population, about 14,300,000 belong to the German race, 2,900,000 to the Slavic, 30,000 to the Celtic (French), 170,000 to the Lithuanian, and 225,000 to the Semitic stock (Jews). The Slavi are principally Poles in the eastern provinces, beside a small number of Moravians and Bohemians in Silesia and Wends in Lusatia. The rural portions of the eastern provinces excepted, German is the common language. The principal cities and

wns are Berlin, the capital of the kingdom;
nigsberg, capital of Prussia proper; Dant-
, Memel, Posen, Stettin, Stralsund, Breslau,
gdeburg, Erfurt, Münster, Cologne, Coblentz,
eves, and Aix la Chapelle.—By far the
rgest portion of the Prussian territory be-
ngs to the great plain of northern Europe.
e eastern provinces form a level district of
er 50,000 sq. m., intersected by a few incon-
derable hill chains, the highest elevations of
hich do not exceed 700 feet. The S. W.
undary of Silesia is formed by the Riesenge-
rge, or Giant mountains (average elevation
400 feet, highest peak 4,929 feet), and their
ntinuations, the Iser ridge and the Lusatian
ountains. The N. part of the province of
xony, which extends from the river Elbe to
e Werra, is almost a perfect level, interrupt-
only by inconsiderable hills and an isolated
evation of 1,086 feet, the Petersberg, near
alle. The S. portion to the S. W. of the
ver Saale is intersected by projecting spurs
the Harts mountains (highest elevation,
e Brocken or Blocksberg, 3,506 feet), and the
uringian forest (highest elevation the Dol-
ar, 3,184 feet). The W. provinces contain the
W. group of the mountain system of Ger-
any, its numerous ridges having as many
stinct names. The more important are: on
e right bank of the Rhine, the Weser hills,
cluding the picturesque gap known under
e name of Porta Westphalica, the Teutoburg
rest (the battle ground of the Germans and
omans), the Rothhaar hills, the Sauerland
lls, the Seven mountains (Siebengebirge), and
esterwald (2,000 feet); on the left bank of
e Rhine, the Hundsrück (3,000 feet), Hohe
een, and Eifel (1,600 feet). The Hohenzollern
incipalities are intersected by the Rauhe Alp.
-The only coast line of Prussia is on the Bal-
c sea, and has a length of 515 m. The sea
ing shallow near the coast, and full of shift-
g sand banks, there are few good harbors;
e best are Stralsund, Colberg, and Dantzic.
eside the open bays of Bodden, Putziger
Wyck, Prorer Wyck, and Tromper Wyck, there
e several extensive lagoons or haffs, separated
om the open sea by narrow strips of land or
rings of islands. Of these lagoons the Great
d Little Haff, whose head is formed by the
nbouchure of the Oder river, the Frisches
aff, which receives the waters of the Nogat
ver, and the Curisches Haff, are the most ex-
nsive. Of lakes Prussia contains an immense
umber, especially in the level N. E. section,
ut none of them are important either for their
tent or as affording facilities for commerce.
he largest lake in the province of Prussia,
irding, covers an area of only 37 sq. m. The
rovince of Saxony contains a small salt lake
the vicinity of Halle, the Röblinger See.
the Rhenish province the Laacher lake, an
ld crater, nearly 8,000 feet square and over
00 feet deep, fed by 40 springs, is renowned
legendary lore. The total number of lakes
vering not less than 200 acres each is 280,
and their total area 750 sq. m., the aggregate area of all other lakes being 700 sq. m. There are large swamps on the lower course of the Havel, Oder, Warta, and Netze rivers, which attempts have long unsuccessfully been made to drain. All the river systems of Prussia belong to the basins of the Baltic and North seas. The principal rivers in the eastern section are the Memel, Vistula (with its tributaries the Drewenz, Ossa, Brahe, and Mottlau), Oder (with its tributaries the Oppa, Ohlau, Bartsch, Bober, Neisse, and Warta), and Elbe (with its tributaries the Saale and Havel with Spree). Independent of these are a number of coast rivers, viz., the Dange, Pregel, Elbing, Leba, Lupow, Stolpe, Wipper, Persante, Rega, Ucker, Ihna, Peene, and Recknitz, nearly all of them navigable for some distance. The western section is watered by parts of the river systems of the Werra, Ems, and Rhine. The Rhine flows through Prussian territory a distance of 185 m., receiving on the right bank 8 tributaries, viz., the Lahn, Wied, Sieg, Wupper, Ruhr, Lippe, Berkel, and Vechte; and on its left bank the Nahe, Moselle, and Ahr. Beside its rivers Prussia has a large number of artificial water courses, the Vistula and Oder being connected by the Bromberg canal, the Oder and Spree by the Müllrose canal, and the Havel and Elbe by the Plane canal. Other canals connect small adjacent river systems in the western provinces.—The climate of Prussia is wholesome and temperate, though an extent of 17 degrees of longitude necessarily produces considerable diversity in the temperature and atmospheric changes. The mean temperature at Königsberg is 42.10° F., at Berlin 46.2°, at Aix la Chapelle 48.87°, and at Cologne and Treves 50°. The soil, though in some mountainous districts of the western section extremely desolate and sterile, and a poor loamy sand in a large division of the middle provinces, is on the whole fertile, and preëminently so in the bottoms of the Elbe, Saale, Unstrut, Oder, Warta, Netze, and other rivers in Pomerania and Silesia. Even where it is naturally poor, a well developed system of agriculture, assiduously fostered by the government, renders it highly productive. Of the total area of the kingdom, 42 per cent. consists of tilled fields, 1.2 gardens, vineyards, and orchards, 7.4 meadows, 7.6 pasture, 18.2 woodland, and 23.6 waste land, lakes, &c. All kinds of grain are produced in abundance in Prussia proper, Posen, Silesia, and Saxony, all of which export breadstuffs to the other provinces or to foreign countries. A full grain crop is estimated at 60,000,000 bushels of wheat, 90,000,000 of rye, 28,000,000 of barley, and 95,000,000 of oats. Of potatoes about 420,000,000 bushels are raised. In 1859 there were 7,764 breweries and 6,541 distilleries, consuming 5,000,000 bushels of grain and 30,000,000 of potatoes. Spelt, peas, rape seed, dye stuffs, herbs, flax, hemp, chicory, hops, and beets are cultivated in large quantities in all parts of Prussia. During the year ending Aug. 31, 1860, 221

beet sugar manufactories produced over 200,000,000 lbs. of sugar from 29,594,342 cwt. of beets. Tobacco enters largely into the agricultural production of western and central Prussia. The tobacco fields cover an aggregare area of 30,000 acres, yielding about 25,000,000 lbs. Of 40,000 acres of vineyards full ¾ are on the Rhine and its tributaries. Their average yield during 27 years was 6,852,895 galls., but in one year (1834) it was as much as 17,494,040 galls. Wine of good quality is produced only near the Rhine; those brands which are produced in Saxony (Naumburg) and Silesia (Grüneberg) are proverbially bad. Fruit culture has been greatly improved in Prussia within the last quarter of a century. The forests, covering an aggregate area of 12,471,388 acres, furnish an abundance of excellent timber and lumber. In the raising of domestic animals the progress of Prussia since its reconstruction after the wars of Napoleon has been more marked than in any other branch of agricultural pursuits. The number of sheep nearly doubled from 1816 to 1849, but the improvement in quality has been still greater than the increase in number. The breed of horses has been so improved by government studs, that not only are all the horses wanted for army purposes obtained within the state, but large numbers are exported to neighboring countries. In 1853 the total number of horses in Prussia was 1,575,000, and of horned cattle 4,372,000. Hogs are bred to a greater extent in Westphalia than in other pr geese in Pomerania, bees in Brand Westphalia, and Lusatia, and goats mountainous districts; poultry is al everywhere. The fisheries on the sh the Baltic and on the lakes and rivers portant, and all kinds of game common tral Europe are found in the forests. are seen only in Prussia proper and where also a few bisons and elks are ca preserved. The lynx, fox, badger, beaver, and otter, and wild fowl are less commonly met with in different pa the kingdom. Seals are sometimes ca the Baltic.—Mining industry advanced astonishing rapidity within the second of the present century, but its further received a check in 1858, from which not yet recovered. In 1852 the total of mines in Prussia was 3,088, viz.: mines, 440 brown coal, 1,615 iron, 153 zinc, 69 copper, 9 vitriol, 5 arsenic, 5 antimony, 5 manganese, 2 cobalt, 1 fluor and 2 graphite, employing 114,832 me 195,930 women and children; of fur rolling mills, &c., 1,183, employing 59,5 and 124,141 women and children; of salt 23, employing 2,275 men and 5,313 and children. The total value of mining ucts in 1856 was $21,582,100; in 1857, $ 725,000; in 1858, $25,125,000; in 185 $ 623,740. The production of the principal erals has been as follows:

Years.	Coal, tons.[*]	Brown coal, tons.	Iron ore, cwt.	Zinc ore, cwt.	Copper ore, cwt.	Lead [illegible] cwt.
1851	22,672,566	10,043,190	18,788,960	3,006,806	968,284	[illegible]
1852	25,788,208	11,761,846	14,045,890	3,620,960	1,243,093	[illegible]
1853	28,688,165	12,200,687	14,965,160	3,246,660	1,255,247	[illegible]
1854	34,014,698	12,365,825	21,938,390	3,578,577	1,244,781	[illegible]
1855	40,789,129	13,774,880	22,282,170	4,287,298	1,278,799	[illegible]
1856	44,288,456	15,556,289	30,681,780	4,532,498	1,431,638	[illegible]
1857	47,388,512	18,244,428	33,811,690	4,377,789	1,308,465	[illegible]
1858	52,086,479	19,889,014	30,786,780	4,887,845	1,833,883	[illegible]
1859	48,604,183	20,849,641	21,425,560	5,565,541	1,427,977	[illegible]

The total value of the products of furnaces, founderies, puddling works, &c., in 1856, was $55,650,000; in 1857, $55,825,000; in 1858, $56,000,000; in 1859, $46,883,123. The q tities produced during the 10 years from 1 to 1859 were:

Years.	Pig iron and castings, cwt.	Iron bars and rails, cwt.	Zinc, cwt.	Lead and litharge, cwt.	Copper, cwt.	Silver, marks[†]
Average 1849-'51	2,578,276	2,540,450	555,364	110,718	23,207	[illegible]
" 1852-'54	4,168,189	4,044,406	723,903	162,573	23,219	[illegible]
1855	5,858,072	4,610,868	765,081	222,810	33,010	[illegible]
1856	7,072,766	5,833,780	766,521	245,719	34,251	[illegible]
1859	7,829,711	5,866,951	1,260,812	304,617	63,927	....

Gold is obtained only in very small quantities, averaging about 30 lbs. a year. Of arsenic the product in 1857 was 4,131 cwt.; of smalt, 1,526 cwt.; of antimony, 227 cwt.; of nickel, 315 cwt. Of salt there was produced, in 1855, 244,136,000 lbs.; in 1856, 254,952,000; in 1857, 302,296,000. Other mineral products of Prussia are agate, amethyst, chrysoprase, alabaster, marble, tophus, millstone, limestone, gypsum, slate, porcelain clay, pipe clay, and marl. Amber, which is fished from the sea or dug from the beach of the Baltic in large quantities, is properly a vegetable product, though so times classed with minerals. Among the m eral springs of Prussia (108) the following joy the widest reputation: Warmbrunn, brunn, Reinerz, and Landeck in Silesia; Fr enwalde in Brandenburg; Lauchstädt in S ony; Driburg in Westphalia; and the sul springs of Aix la Chapelle.—The manufactur industry of Prussia is comparatively of re growth. Up to the beginning of the pres century Prussia was mainly an agricultural military state. Even the efforts of Frede e Great to diversify the occupation of his eople by introducing new branches of manu- acture were in the main unsuccessful, proving hat arbitrary decrees are unable to lead an gricultural people to industrial pursuits while he freedom of labor is restricted by political stitutions. It was only after the ultimate bolition of serfdom (Oct. 9, 1807), the intro- uction of municipal self-government (Nov. 19, 808), and the removal of the mediæval institu- ion of trade guilds (Oct. 28, 1810), that manu- acturing industry began to take root in Prus- ia under the shelter of the prohibitory system ntroduced by Napoleon. After the downfall f Napoleon the Prussian government at first bandoned his commercial policy, but the un- xampled distress created in a large portion of he kingdom by a perfect inundation of cheap nglish goods and the rapid decrease of domes- ic production compelled the government to nact a moderately protective tariff (1818) and o consolidate the industrial interests of a large art of Germany. Since then the industry of russia has steadily and rapidly advanced un- er a commercial policy that, while removing s far as possible all internal restrictions and reating new domestic markets by establishing eciprocal free trade with a majority of the erman states (*Zollverein*), afforded protection gainst foreign opposition to those branches f industry which, from the want of accumu- ated capital, would have been crushed if they ad not been so protected. In 1806 the pop- lation of Prussia was 10,000,000, with an verage income of $10 to each inhabitant; the apital invested in manufacturing establish- ents little exceeded $200,000,000, and the umber of free laborers was 490,000. In 1856 he average income of over 17,000,000 inhab- ants was $43 each, the capital invested in man- factures $770,000,000, and the number of free aborers 2,771,000. It is true that within this eriod the territory of the kingdom has been onsiderably increased; still the fact remains hat with an increase of population of only 70 er cent. the products of labor have increased n value at least 300 per cent. A large share f this increase belongs to the agricultural pro- uction, the progress of which has been stimu- ated by the increase of domestic consumption. he total value of agricultural products was stimated in 1856, by the agricultural depart- ent of the government, at $282,755,560, more han double the amount of the total production f Prussia 50 years ago. In the same year the et income of 363,676 merchants, manufactu- ers, shippers, &c., was estimated at $260,000,- 000; of 2,770,498 free laborers at $80,000,000; f 325,024 tradesmen at $75,000,000; of 116,671 rofessional men at $35,000,000; and of 100,000 aborers at $5,000,000. Extensive branches of anufacturing industry have been created in russia, as it were, from nothing. Among hese the manufacture of beet sugar stands fore- ost. The introduction of the cotton manu- acture has been attended with great hardship. In 1846 the number of spindles was 194,290, which had increased to 289,000 in 1856. Their number at the close of 1857 was estimated by the minister of commerce at little less than 400,000. Since then there has been but little if any increase. The linen manufacture has suffered more than any other branch of industry from British competition. For some time the manufacturers endeavored to undersell the British by reducing wages. The sufferings produced by this proceeding among the weavers of Silesia form one of the darkest episodes in the history of Prussia. The most prosperous departments of mechanical industry are the manufactures of woollen goods, silks, and hardware. While 40 years ago Prussia exported the largest portion of its raw wool, its imports of the raw material and woollen yarns now exceed its exports. The total value of cloths manufactured in the Zollverein in 1852 was $84,000,000, of which nearly $16,000,000 worth was exported. The domestic consumption of cloth, which in 1806 averaged only ⅓ ell to each inhabitant, increased to 1½ ells in 1849, and to 3½ in 1852. Within a period of 10 years (1842 to 1852) the net value of cotton fabrics exported by the Zollverein, exclusive of the cost of raw material, increased from $6,500,000 to $13,000,000. The Rhenish province, Westphalia, and Saxony are the principal seats of the manufacture of textile fabrics. Hardware of all kinds is manufactured in all the provinces except Prussia proper and Posen. The machine shops of Berlin rival the largest establishments of the same kind in England. Solingen and Suhl are celebrated for cutlery and guns; Silesia for castings and sheet iron; Westphalia for scythes and needles. Rapid as the increase of the production of raw iron has been in Prussia, it has not been able to keep pace with the increase of consumption. With a home production of 5,858,072 cwt. of pig iron in 1856, Prussia imported 2,604,465 cwt., making the total consumption 8,462,537 cwt. The imports in 1857 were 4,161,357 cwt., which, added to the home production of nearly 7,500,000 cwt., shows a total consumption in that year of over 11,600,000 cwt., an increase of 3,200,000 cwt. or 40 per cent. in 2 years. The manufacture of leather, morocco, cordovan, &c., flourishes in the province of Saxony, Berlin, and in Prussia proper. In the manufacture of paper the progress has been more rapid even than in textile fabrics; it is carried on in the Rhenish province, Westphalia, Brandenburg, Saxony, and Silesia. Chicory and starch are manufactured principally in the province of Saxony, tobacco in all parts of the kingdom. The most extensive copper and brass manufacturing establishments are found in the province of Saxony and on the Rhine. Glass ware, crockery, stone ware, and china are produced in large quantities, principally in the central and eastern provinces. The porcelain of Berlin rivals the best French china ware. Tassels, fringes, trimmings, &c., are manufactured at Breslau, Magdeburg, Cologne, and Berlin; furniture and pianos at Berlin. In most of these departments of industry the production is fully or nearly equal to the consumption, the imports into Prussia of such goods being balanced by exports to a similar amount. The employment of steam power has increased 1,200 per cent. within 20 years. In 1837 there were in Prussia 423 steam engines, of an aggregate of 7,513 horse power; in 1852, 2,832, of 92,462 horse power; in 1859, 8,878 engines (aggregate horse power not stated, but probably 300,000). Of these there were employed in cotton mills 878, in machine shops and metal manufacturing establishments 1,691, in grist and saw mills 806, in mining 1,498, in navigation 117, on railroads 1,264, and for various other purposes 2,624. The total number was distributed among the different provinces thus: Rhenish Prussia 2,153, Westphalia 1,656, Saxony 1,650, Silesia 1,352, Brandenburg 1,190, Prussia proper 878, Pomerania 298, Posen 201.—With the exception of England, no other country has such excellent postal facilities as Prussia. The number of post offices increased from 1,819 in 1855 to 1,956 in 1857; the aggregate number of miles over which the mails were carried, from 18,880,000 in the former year to 20,250,000 in the latter. The number of letters carried in 1860 was 135,377,086. The drop letter delivery in the large cities of Prussia is the most punctual in the world. In 1857 the number of letters delivered in Berlin was 7,190,693, of which 2,148,410 were drop letters. The single postage is 2½ cts. for any distance under 46 m., 4¾ cts. for any distance from 46 to 92 m., and 7 cts. for any distance above 92 m. The postal establishment is not only self-sustaining, but yields a profit to the government. In 1857 the total receipts were $8,523,578, and the disbursements $7,148,516. The telegraphs all belong to the government. Their aggregate length was 2,616 m. at the close of 1854, 3,650 m. at the close of 1857, and 4,450 on Jan. 1, 1859. From 1854 to 1857 the number of messages increased from 152,820 to 241,545. The limited number of stations renders the telegraph of much less value for commerce than it is in England or America.—On Jan. 1, 1860, there were 22 railroad lines and portions of 7 incomplete lines in operation. The total length of the former was 3,107 m., of which 776 were built on government account at a cost of $48,343,840; of the latter, 276 m. The aggregate cost of the completed lines was $205,991,587, or an average of $66,299 a mile, the average being much lower on the roads built by government. The rolling stock consisted of 1,259 locomotives, 1,975 passenger cars, and 32,794 freight cars. The number of passengers carried over the roads in 1859 was 20,161,218; total freight 241,621,312 cwt. The receipts were $23,586,904, or an average of $7,590 per mile; total expenditure $11,008,468, or an average of $3,543 per mile, leaving interest on the capital at the rate of 6.11 per cent., against 6.56 in 1858. Of gravelled turnpike roads there were under the charge of the state government, Jan. 1, 1858, 8,868 m.; of turnpikes built and maintained on account of districts, corporations, mining companies, &c., 6,561 m. The length of river navigation is 3,631 m., and of canals 443 m. Since railroads have entered into competition with river navigation, the number of river craft has been diminished, while their tonnage has increased and is now nearly 800,000 tons. Steamboats ply on the Rhine, Moselle, Weser, Elbe, Havel, Spree, Peene, Oder, and Vistula. In 1859 there arrived in Cologne, the principal port on the Rhine, 1,124 sailing vessels, carrying 90,690 passengers and 81,639 cwt. of freight, while some 30 steamboats carried 574,495 passengers. The coasting and foreign commerce is carried on from 20 ports on the Baltic, of which Dantzic, Pillau, Elbing, Memel, Stralsund, and Stettin are the most important. The commercial marine, including river steamers, increased from 933 vessels of 278,250 tons in 1854 to 1,326 vessels of 339,442 tons on Jan. 1, 1861, and the number of steamers from 29 to 85 within the same period. Of the total number of vessels, 901 were sea-going sailing craft of 316,200 tons, 340 coasting vessels of 12,978 tons, 24 ocean steamers of 6,780 tons, and 61 river steamers of 3,584 tons. The movements of shipping in 1859 and 1860 were as follows:

---

[*] 1 ton = 4 scheffels = 6.236 bushels.

[†] 1 mark = 0.62656 lb. troy.

Years.	Entered.		Cleared.	
	Vessels.	Tonnage.	Vessels.	Tonnage.
1859	9,116	1,471,569	9,197	1,614,[illegible]
1860	11,671	1,884,731	11,868	1,940,944

Of the entrances in 1859, 5,121 vessels were Prussian and 3,995 foreign, and of the clearances 5,188 Prussian and 4,009 foreign; of the entrances in 1860, 5,828 sailing vessels and 727 steamers were Prussian, and 5,806 sailing vessels and 310 steamers foreign, and of the clearances 5,587 sailing vessels and 723 steamers were Prussian, and 5,280 sailing vessels and 309 steamers foreign. Of the tonnage inward in the latter year, 1,617,150 belonged to sailing vessels and 267,582 to steamers, and of the tonnage outward, 1,682,674 to sailing vessels and 258,270 to steamers. Among the arrivals and departures in 1860 there were but 2 vessels from the United States, tonnage 1,562. Distinguishing between vessels with cargoes and vessels in ballast, among the former the Prussian bottoms constituted 56.78 per cent. of the arrivals and 49.83 per cent. of the departures: among the latter 39.77 per cent. of the arrivals and 62.52 per cent. of the departures. Of the vessels cleared from Prussian ports, there were 9,659 loaded and 1,158 only in ballast; of the arrivals, 6,458 loaded and 4,176 in ballast, showing that the export trade of Prussia is much heavier than the import trade. The coasting trade is free to those nations which extend the same privilege to Prussian bottoms. As yet the progress of the shipping interest has been rather irregular in Prussia. The exportation of breadstuffs and lumber from the eastern provinces to England (the average export of the former approached 1,000,000 quarters after the repeal of the British corn laws) has suffered by the competition of the United States and the Danubian countries; and the investment of capital in the shipping business has been very slow, if it has not actually decreased since the admission of foreign bottoms to the coasting trade. The principal marts of the interior commerce are Berlin, Breslau, Magdeburg, Frankfort, Cologne, Elberfeld, and Münster. The principal articles of export are wool and woollen fabrics, breadstuffs, linseed, rape seed and rape seed oil, flax, linen, and cotton goods, wine, lumber, salt, amber, coal, iron, zinc, lead, hardware, dye stuffs, books, leather, and dyed yarn. The imports consist of molasses and sugar, coffee, wine, rum, arrack, tobacco, cotton, raw silk, tea, spices, hops, dye woods, tin, quicksilver, saltpetre, glass, cattle, dried and salt fish, train oil, and furs. The import duties being specific and levied on behalf of the Zollverein, it is difficult to ascertain the value of the foreign commerce of Prussia, nor do the official triennial reports of the minister of commerce contain any general statistics under this head. The last of these reports (1855-'7) gives the following account of the commerce of Stettin:

Years.	Imports, cwt.	Value.	Exports (exclusive of lumber), cwt.	Value.
54	[illegible]	[illegible]	1,213,772	[illegible]
55	4,476,224	12,104,251	[illegible]	[illegible]
56	6,261,370	14,001,417	[illegible]	[illegible]
57	[illegible]	[illegible]	[illegible]	12,791,772

that in this table the average value of goods is estimated at a higher rate in 1856 and 1857 than in the two preceding years.—The banking establishments of Prussia are hampered by government monopolies, and are not in proportion to the wants of commerce. Until 1855 the royal bank at Berlin (which had been transformed into a joint stock bank in 1846) was the only bank of issue. Since then 8 private joint stock banks have been established under a sort of free banking act, which however offers few inducements to capitalists. The note circulation of every private bank is limited to $700,000. The circulation of the royal bank, which until 1850 had not exceeded $15,000,000, rose to $50,000,000 in 1857, but has since decreased. In all the principal cities there are branch establishments of the royal bank. The number of banking establishments not authorized to issue notes increased from 64 in 1854 to 108 in 1857. A peculiar moneyed institution of Prussia, first introduced by Frederic the Great, but since then imitated in other countries, is the real estate bank, originally intended to save the large landholders from the usurious practices of money lenders. These banks issue transferable mortgage bonds to the amount of one half or two thirds of the value of landed estates, the bank or association of landholders guaranteeing the principal and interest to the holders of the bonds. The aggregate amount of such bonds exceeds $100,000,000. The association of capital for commercial and industrial purposes, not including railroads, turnpikes, or canals, has greatly increased within the last decade. From 1852 to 1854 inclusive 45 joint stock companies were formed, representing an aggregate capital of $30,000,000; from 1855 to 1857 inclusive, 75, with an aggregate capital of $45,792,600. Of the latter, 38 (capital $25,792,100) were mining companies, 8 (capital $6,125,000) insurance companies, 16 (capital $8,337,700) manufacturing companies, and 7 (capital $4,900,000) banking companies. Savings banks in Prussia are municipal institutions, doing only local business. Their number in 1859 was 462. The aggregate deposits in them on Jan. 1, 1858, were $28,704,150; 1859, $31,290,517; 1860, $31,696,761. The depositors on Jan. 1, 1860, were 564,986, of whom fewer than one fourth (125,031) held over $70 each.—Public education is better provided for in Prussia than in any other European country, or in fact any other country, some of the New England states excepted. Instruction in the common branches of learning, reading, writing, and arithmetic, is compulsory. In fact, it is difficult in Prussia to find adult persons unable to read. The number of common schools is 24,800, with 31,000 teachers and over 2,500,000 pupils. The number of "middle schools," academies, apprentices' schools, Sunday schools, and industrial schools is very large, and increasing from year to year. Of apprentices' schools (*Handwerker-Fortbildungs-Schulen*) there were in 1859 297, with 23,625 pupils. There were 21 provincial technical schools (*Gewerbe-Schulen*), attended by 1,049 persons. In 1859 there were 84 higher (common) schools (*Bürgerschulen*); 52 colleges for instruction in the exact sciences (*Realschulen*); 129 classical colleges (*gymnasia*), with 1,700 teachers and 30,000 students; 39 preparatory colleges (*progymnasia*), with 190 teachers and 2,000 students; 56 normal schools; 6 universities (at Berlin, Königsberg, Halle, Breslau, Greifswalde, and Bonn); and 2 Roman Catholic theological academies, with over 5,000 students. Beside these there are numerous educational institutions for special branches of science, viz.: theological seminaries connected with the universities; a philosophical academy at Paderborn; 9 Roman Catholic seminaries; 3 seminaries for the higher branches of school teaching; a polytechnic institution and an academy of architecture at Berlin; mining academies at Berlin, Bonn, and Halle; an academy of veterinary surgery at Berlin; an academy of forest culture at Neustadt-Eberswalde; agricultural colleges at Eldena, Proskau, Poppelsdorf, and Möglin, and 25 agricultural schools; schools of horticulture at Potsdam and Schöneberg; academies of surgery at Berlin, Breslau, Greifswalde, Magdeburg, and Münster; 7 military academies; 7 nautical schools; and a great number of private commercial academies. All educational institutions are controlled, more or less directly, by the government. Even private teachers must submit to a thorough examination before they are permitted to open schools. The common schools are sustained and administered by the municipal corporations, but the teachers are appointed by government. Of charitable institutions, there are deaf mute asylums at Berlin, Königsberg, Breslau, Münster, and Cologne; asylums for the blind at Berlin and Breslau; a number of orphan asylums and nurseries, of which Berlin alone has over 40; 95 Bible societies, a missionary society at Berlin, &c. The highest branches of scientific culture are fostered by the royal academy of Berlin, and numerous associations of scholars, philosophical, geographical, historical, medical, legal, and polytechnic societies. There are large public libraries in all the principal cities; observatories and botanical gardens are connected with the universities; a zoological garden is kept near Berlin. The fine arts are taught by the royal academy of art at Berlin, the academy of design at Düsseldorf, 5 provincial academies of design, and an academy of chartography. The number of musical academies and musical societies is enormous. The newspaper press has not yet in Prussia attained to the same prosperity, power, and influence which it enjoys in England and America; but its progress since the revolutionary movements of 1848 has been strongly marked. There is no centralization of the newspaper press, many of the large provincial daily journals being fully equal, or even superior, in importance and circulation to the metropolitan press.—The dominant religion in Prussia is the Protestant. The two principal Protestant denominations (the Lutheran and the Reformed or Calvinistic church) united in 1817, assuming the common designation of Evangelical church. According to the last full census there were in Prussia 10,874,774 Evangelical Christians, 6,832,293 Roman Catholics, 1,485 Greek Catholics, 15,000 Moravians, 20,000 Herrnhuter, and 226,868 Jews. The number of Protestant churches and meeting houses is 9,000, of Roman Catholic churches and chapels 7,250, of Jewish synagogues 900. The people of Posen, Westphalia, and the Rhenish province are almost wholly Roman Catholic. The Evangelical is the established church. It is governed by the supreme ecclesiastical council at Berlin (established in 1850) in all spiritual matters, and by the ministry of public worship in temporal affairs. Each province has a consistory, and is divided into dioceses, at the head of which stand superintendents or bishops. Of such dioceses Prussia proper has 51, Posen 18, Brandenburg 76, Pomerania 56, Silesia 52, Saxony 95, Westphalia 19, and Rhenish Prussia 25. The Roman Catholic church has 2 archbishoprics (Posen and Cologne) and 6 bishoprics (Culm, Ermeland, Breslau, Münster, Paderborn, and Treves). Of the Jews fully one half live in the eastern (formerly Polish) provinces. The members of all chur recognized by government enjoy equal rights. Other denominations (Baptists, M odists, German Catholics, and Free Congre tionalists) are barely tolerated, though the stitution guarantees full religious liber Prussia is a hereditary constitutional mona The constitution promulgated Jan. 31, guarantees to all citizens equality in rights, the right of habeas corpus, reli liberty, freedom of the press, &c. The ki the chief executive, clothed with all pre tives of monarchical power. He admini the government by the advice of 10 respon ministers, viz.: the secretaries of state, royal household, of foreign affairs, of the rior, of public worship, education, and hea commerce, industry, and public works, of tice, of the treasury, of war and the navy of agriculture. The legislature consists house of lords and a chamber of dep To the former belong all princes of the al blood, all princes formerly sovereign now subject to the king of Prussia, hered peers, peers for life, 90 members elect the wealthiest classes, and 30 members el by the municipal corporations of as many p cipal cities. The chamber of deputies co of 352 members, who are elected by rect universal suffrage for a term of 3 y The legislature may originate bills, but king has an absolute veto power. As yet constitution has been of scarcely any pra value. The rights it guarantees have overridden by police regulations, the resp bility of the ministers has remained a dea ter, and the legislature has been power either for good or evil on account of the in gruity of its component elements. At the h of the political administration of each prov stands a chief president. The provinces divided into administrative districts (*Reg ungsbezirke*), governed by presidents; there 25 beside the city of Berlin and the Hoh zollern principalities, each of which forms separate district. The districts are divi into circles (*Kreise*, 337), governed by pref (*Landräthe*). Provincial assemblies exist, b their powers are only advisory. They can originate any measures, and must not even vise the government upon any subject unle called upon to do so. Their principal duty is apportion the taxes to be levied from the pr inces. The police throughout the kingdom administered by the government. The admin tration of justice has been completely reorgan ized since 1848. Publicity of judicial proceed ings, trial by jury, and a new criminal code ha been introduced, and all exceptional jurisdiction has been abolished. In Rhenish Prussia the code Napoleon and the French legal procedure which were introduced under the rule of Na poleon, have been maintained. In the other provinces there are city or district courts, an 22 courts of appeal. The chief tribunal at Berlin is the court of last resort for all parts of the gdom. The finances of Prussia, which under ederic the Great were the admiration of the orld, have greatly suffered in consequence of he wars of Napoleon, and the revolution of 848. The army and navy consume $\frac{1}{4}$ of the tire income of the nation, and within the last 0 years the military expenses have increased om $17,500,000 to $26,950,000, or 54 per cent. he following table shows the state of the russian finances since 1848, the sums being iven in thalers, of 70 cents each:

Years.	Ordinary revenue.	Expenditure, ordinary and extraordinary.	Deficiency.
[illegible]	92,424,291	97,424,291	5,000,000
[illegible]	[illegible]	[illegible]	4,281,189
[illegible]	86,721,860	[illegible]	3,072,672
[illegible]	94,177,[illegible]	96,511,[illegible]	[illegible]
[illegible]	97,559,[illegible]	101,150,[illegible]	[illegible]
[illegible]	[illegible]	107,[illegible]	[illegible]
[illegible]	[illegible]	[illegible]	[illegible]

[illegible]	[illegible]	[illegible]	none
[illegible]	[illegible]	[illegible]	none
[illegible]	[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]	[illegible]

he government owns 740,925 acres of cultiated land, from which it obtains a rental of ver $2,000,000, and 5,109,769 acres of forests, eside mines, salt works, railways, &c. The llowance to the king and royal family, $1,791,-71, is deducted from the income of the state omain, and the remainder goes into the treasry. The revenue is made up by a complicated stem of direct and indirect taxation. Of the tal revenue about $19,000,000 is derived from rect taxation, $25,000,000 from indirect taxaon, $16,000,000 from the post office, the govrnment monopoly on salt, and state lotteries, 7,000,000 from landed estates belonging to govrnment, and $27,000,000 from miscellaneous urces. The exemption of a large number of nded proprietors (noblemen) from taxation real estate renders the taxes more oners than they would be under a fair and equible apportionment. The public debt, which 1787 was only $32,250,000, amounted to 152,491,500 in 1820. During the subsequent riod of peace it decreased to $98,000,000 in 47, but within the next 8 years it again ineased to over $154,000,000, and is now $175,-0,000, exclusive of $17,500,000 debts of the vernment railroads.—The Prussian military ganization is based on the principle that ery citizen owes his services to the country. very Prussian is by law a soldier, though, in nsequence of the limitation of the army to a rtain number of men, all may not be obliged enter the ranks. The regular army consists men from 20 to 25 years of age. Formerly ey had to remain in active service for 2 years ly (with the exception of the royal guards), d were then dismissed to form a reserved regar force liable to be called out at any time r 3 years more. But in 1860 King William, en prince regent, without asking the consent the legislature, increased the regular term active service to 3 years, which is equivalent to an increase of the peace establishment by nearly one third. The term of active service for professional men, students, &c., is one year. Having served his term in the regular army, the Prussian enters the *Landwehr* (militia), which is divided into two levies (*Aufgebote*), the first comprising all men from 26 to 32 years of age, the second all from 33 to 39 years of age. The first levy is called out every year a few weeks for drilling and manœuvring. In war it is employed the same as the regular army. The second levy is liable to be called out in time of war for the purpose of garrisoning the fortresses. All men over 39 and under 60 years of age form the irregular militia (*Landsturm*), which acts as a home guard in case of a foreign invasion. It is only a local force for defensive purposes, never called out except in extreme cases. The regular army is composed as follows: 1. Infantry—*a*, royal guards: 4 regiments of 3 battalions each, 1 reserve regiment of 2 battalions, 1 battalion of sharp shooters, 1 battalion of riflemen; *b*, regiments of the line: 32 regiments of 3 battalions, 9 reserved regiments of 2 battalions, 8 combined reserved battalions, 8 battalions of riflemen. 2. Cavalry—*a*, royal guards: 6 regiments (*garde du corps*, cuirassiers, dragoons, hussars, and uhlans), of 4 companies each; *b*, line: 8 regiments of cuirassiers, 4 of dragoons, 12 of hussars, 8 of uhlans, of 4 companies each. 3. Artillery—*a*, royal guards: 1 regiment of 12 batteries; *b*, line: 8 regiments of 12 batteries each. 4. Pioneers—*a*, royal guards: 2 companies; *b*, line: 8 sections and 1 reserved section, of 2 companies each. The first levy of the landwehr consists of 36 regiments and 8 reserved battalions of infantry (116 battalions), and of 34 regiments and 8 reserved companies (144 companies) of cavalry. The second levy consists of 116 battalions of infantry and 104 companies of cavalry. The artillery belonging to the landwehr has no separate organization, but the men enter the ranks of the regular army whenever it becomes necessary. The army is divided into a corps of guards (head-quarters, Berlin) and 8 army corps (head-quarters, Königsberg, Stettin, Berlin, Magdeburg, Posen, Breslau, Münster, and Coblentz). Each army corps consists of 2 divisions (a division comprises 2 brigades or 4 regiments of infantry, and 1 brigade or 4 regiments of cavalry), 1 regiment of artillery, 1 section of pioneers, 1 battalion of riflemen, 2 reserved regiments, and 1 or 2 companies of veterans. In war, an army corps numbers 25 battalions of infantry (25,000 men), 32 companies of cavalry (4,800), 88 field pieces, 4 reserved battalions, and 6 reserved companies. The total of the Prussian army, according to the new organization of 1861, is, in peace, 212,649, in war, 622,880; while the total number of those who have gone through the military drill and are under 40 years of age is estimated at 855,000 (calculating the decrease by death at 25 per cent.), leaving nearly 230,000 men as a reserved force even after the army has been put upon the war footing. The navy of Prussia is still in its infancy. It consists of 55 vessels, carrying 265 guns. Of this number 42 are gun boats, 4 steamers, 4 corvettes carrying from 10 to 12 guns each, 2 sloops of war carrying 8 guns each, and two transport ships, and one is a frigate of 48 guns.—The country which has given its name to the kingdom of Prussia, of which it is now only a province, was known as early as 320 B. C. by the Phœnicians, who procured amber from the shores of the Baltic sea. The aborigines, a Lithuanian tribe, appear to have been peaceable and quiet, not unacquainted with agriculture, and living under a democratic form of government. During the first centuries of the Christian era, they became dependent upon the Goths, who overran their country. In the 10th century they are first mentioned under the name of Porussi (*po*, behind, people living behind the Russ, a fork of the river Memel). Their religion was polytheism, and human sacrifices were not uncommon among them. Bishop Adalbert, who attempted to convert them to Christianity, was slain by them while hewing down their sacred oak tree, in A. D. 997. Boleslas I., duke of Poland, invaded their country and compelled them to profess the Christian faith in 1015, but neither himself nor his immediate successors could retain a hold upon them. A large army which Boleslas IV. led against the Prussians was totally annihilated, and the Prussians even succeeded for some time in holding a part of Poland in subjection. In 1219 they repelled a crusade sent against them from Germany, and soon became the terror of all neighboring countries. The Teutonic knights finally conquered Prussia (1230–'83), founded cities, introduced German colonists and German laws, and by their firm but liberal rule made Prussia one of the most flourishing countries of its time. But about the middle of the 15th century the demoralization of the knights, their continual wars with Poland and Lithuania, and their reckless exactions created a powerful opposition. The nobility and the municipalities obtained the assistance of the king of Poland, Casimir IV., and by a war of 12 years' duration (1454–'66) compelled the order to cede western Prussia and Ermeland to Poland. The remainder was left to them as a fief of Poland. In 1511 the margrave Albert of Brandenburg was elected grand master of the order. Having vainly striven to throw off the Polish rule, he turned Protestant, and in 1525 accepted Prussia as a duchy from Poland. His son, Albert Frederic, becoming insane, the duchy was governed by his relatives, of whom John Sigismund, elector of Brandenburg, inherited it in 1618. He was a descendant of Frederic of Hohenzollern, burgrave of Nuremberg, who had become possessor of Brandenburg in 1415 by foreclosure of mortgage. It is the electorate of Brandenburg, not Prussia proper, which must be considered the nucleus of the present monarchy of that name. The electorate, though frequently divided by the descendants of Frederic, played a spicuous part in the history of Germa pecially during the reformation. Fred (1415–'40) subdued the robber knights, obtained some additional territory from merania and Mecklenburg, but succumbe the Hussites, who devastated his country fire and sword in 1432. Frederic II. (144 surnamed the Man of Iron, enlarged his sessions by purchases from neighboring but was unfortunate in his attempts to quer Lusatia from Bohemia and Stettin Pomerania. Albert Achilles (1470– John Cicero (1486–'99) contended energet against the usurpations of the lords, an moted industry, commerce, and science. achim I. Nestor (1499–1535) was noted scholar, and also as one of the most violen ponents of the reformation, and a perse of the Jews, of whom he had many at the stake or exiled. Joachim II. (1535–'71) became a Protestant, secula the bishoprics of Brandenburg, Havelber Lebus, founded many educational or char institutions with the proceeds of the property, and concluded a treaty of mutu heritance with the duke of Liegnitz in which became two centuries later the fou tion of the Prussian claims on Silesia. George I. (1571–'98) expelled the Jews wh been readmitted by his predecessor, but in the exiled Protestants from the Nether into his country, and by wise economy gre improved the financial condition of his Joachim Frederic (1598–1608) acquired marriage a claim on the duchy of Pr which his son John Sigismund (1608–'19 manently united to the electorate of Bra burg. Under the reign of George Wi (1619–'40) Brandenburg and Prussia suffe terribly from the 30 years' war. Ha adopted a policy of neutrality, the elector looked upon as an enemy by both conte parties. Prussia was ravaged by Swedes Poles, Brandenburg by the imperial arm the league, and during 12 years by the Swe From the lowest depth of misery and de lation the country was raised by the ene and wisdom of Frederic William, the G Elector (1640–'88). By marking out a vi ous and independent policy against Fra Sweden, and Poland, and shrewdly taking vantage of dissensions among his enemies enlarged his dominions and obtained a pos but little below that of the great powers Europe. Of Prussia he made a sove duchy, severing its connection with Po At his death his possessions had increased 42,320 sq. m. with 1,500,000 inhabitants. son Frederic, the third elector of that na (1688–1713), by consent of the German peror, assumed the title of king in Pru He acquired a few small territories, the pri pality of Neufchâtel in Switzerland among rest. His son Frederic William I. (171 acquired from Sweden a part of Pomerania ith Stettin, increasing the area of the country 46,000 sq. m. He left to his son Frederic II., e Great (1740-'86), $6,000,000 over and above l debts, and an army of 70,000 men, the best isciplined in all Europe. With these means rederic began a war of conquest, and wrested ilesia from Austria. By a wise and prudent dministration he strengthened and consoli ated his kingdom, and elevated it to the rank f a great power by successfully resisting dur g a sanguinary war of 7 years' duration 1756–'63) the combined aggressions of Aus ria, France, and Russia. In 1772 he took art in the first partition of Poland. To his uccessor he left a treasure of $50,000,000, an rmy of 220,000 men, and a territory of 77,000 q. m. On his accession he had 2,240,000 sub ects, and at his death the number exceeded ,000,000. Frederic William II. (1786–'97) ried his best to undo the work of his great redecessor, but failed to destroy the prestige f Prussia, and by participating in the second nd third partitions of Poland added to his ossessions 40,000 sq. m. Frederic William II. (1797-1840), by a weak and vacillating olicy, isolated Prussia and encountered the rath of Napoleon, who, after an ignominious efeat of the Prussian armies in 1806, reduced e kingdom to less than ½ its former area. For years Prussia chafed under the iron hand of apoleon, who did his utmost to reduce the ingdom to its former condition as an unimpor ant margraviate. But during this period the tatesmen of Prussia laid the foundation of its ubsequent greatness by unfettering labor and ommerce, by granting municipal self-govern ent, and basing the military power of the tate upon the people. After the downfall of apoleon most of its former possessions were estored to Prussia, and in addition to them it cquired parts of the kingdom of Saxony and f Pomerania, Berg, Jülich, and several val able territories on the Rhine. The promise f a liberal constitution, given by the king to is people, was not kept. The political condi ion settled down into a sort of patriarchal des otism. The establishment of the Zollverein as the only wise and statesmanlike measure uring 25 years of peace. Frederic William V. (1840-'61), a man of great natural talents nd scholarship, but weak, pusillanimous, and indictive, destroyed almost totally the moral restige of Prussia, and threw away the golden pportunity, offered to him by the revolution f 1848, of becoming the head of a united Ger an nation. For nearly 10 years under his eign the reactionary party of the country ielded a despotic power almost oriental. In 1857 his mental faculties gave way, and his rother William was intrusted with the re ency. Frederic William died Jan. 2, 1861, and as succeeded by the regent as William I., who romised faithfully to execute the constitution, nd was generally credited with a desire of gain restoring Prussia to the political leader hip in Germany.

PRUSSIA PROPER, a great division of the Prussian kingdom, comprising East or Ducal Prussia, and West or Royal Prussia; area, 24,926 sq. m.; pop. in 1858, 2,744,500. East Prussia is bounded N. E. and E. by Russia, S. by Poland, W. by West Prussia, and N. W. by the Baltic. Its surface is low and almost uniformly level, and along the sea coast there are numerous lakes formed by the rivers, the fall being insufficient to carry their waters to the ocean. The most important streams are the Memel or Niemen, which forms a vast estuary or lagoon called the Curische Haff, the Pregel, the Tange, and the Passarge. The greater part of the soil is fertile, and the principal crop is potatoes. Nearly ¼ of the land is covered with forests. Fruit, flax, hemp, tobacco, grain, live stock, fowls, and game are largely produced, and amber is found in considerable quantities. East Prussia comprises the governments of Königsberg and Gumbinnen. Most of the inhabitants are Germans. West Prussia is bounded N. by the Baltic, E. by East Prussia and Poland, S. by Poland, and W. by Brandenburg and Pomerania. The surface, soil, and productions are like those of East Prussia. The principal rivers are the Vistula, whose E. mouth, the Nogat, enters the Frisches Haff, the Drewenz, Sorge, Mottau, Brahe, and Schwarzwasser. There are numerous inland lakes, but they are not so large as those of East Prussia. This division comprises the governments of Dantzic and Marienwerder. The inhabitants are chiefly Poles.

PRUSSIAN BLUE. See POTASSIUM.

PRUSSIC ACID. See HYDROCYANIC ACID.

PRUTH (anc. *Porata*), a river of Europe, which rises in the N. E. Carpathians on the confines of the Hungarian county of Mármaros and Galicia, flows in an E. direction through the latter country and Bukovina, and in a S. S. E. direction along the boundary line of Moldavia and Bessarabia, joining the Danube at Reni, near the delta of the latter river. The affluents of the Pruth are numerous but unimportant. Kolomea, the capital of a circle of the same name in Galicia, and Czernowitz, the capital of Bukovina, are situated on its banks. The Pruth figures conspicuously in the history of the Turko-Russian wars since the times of Peter the Great, who was nearly compelled to surrender on its banks in 1711.

PRUTZ, ROBERT ERNST, a German poet and historian, born in Stettin, May 30, 1816. He was educated at Berlin, Breslau, and Halle, at which last place he became extraordinary professor of literary history in 1849. He has written poems, dramas, romances, and works in literary history and criticism. Of the last the most noteworthy are: *Der Göttinger Dichterbund* (Leipsic, 1841); *Geschichte des Deutschen Journalismus* (vol. i., Hanover, 1845); *Vorlesungen über die Geschichte des Deutschen Theaters* (Berlin, 1847); *Kleine Schriften zur Politik und Literatur* (2 vols., Merseburg, 1847); and *Neue Schriften* (2 vols., Halle, 1854). His principal dramatic works are *Moritz von Sachsen* and *Die politische Wochenstube;* and his best romances, *Das Engelchen* (3 vols., Leipsic, 1851), *Felix* (2 vols., 1851), and *Der Musikanten-Thurm* (3 vols., 1855).

PRYNNE, William, an English author and politician, born at Swainswick, near Bath, in 1600, died in London, Oct. 24, 1669. He was graduated at Oriel college, Oxford, in 1620, studied law, and was admitted a barrister, bencher, and reader of Lincoln's Inn. Having embraced the extreme views of the Puritans, he published several pamphlets against Arminianism. In 1632 he wrote a volume entitled "Histriomastix, the Player's Scourge," in which he attacked theatres, masks at court, dancing, hunting, May poles, cards, and music. Laud, who twice before had endeavored to convict him before the high commission court, took advantage of some passages which appeared to reflect upon the king and queen to bring him before the star chamber, and by that court he was excluded from Lincoln's Inn, and condemned to pay a fine of £5,000, to have his ears cut off, to stand in the pillory at Westminster and Cheapside, and to be imprisoned during the king's pleasure. His work was also ordered to be burned before his eyes by the common hangman. This severe sentence, which was rigorously carried out, did not subdue his spirit, and from his prison he continued to issue tracts against the prelates, calling them, according to Wood, "Luciferian lord bishops, execrable traytors, devouring woolves, with many other odious names not fit to be used by a Christian." The publication of one of these, in 1637, entitled "News from Ipswich," stirred up anew the anger of Laud, and Prynne was again summoned before the star chamber, and fined £5,000. His ears, which had been sewed on, were also again cut off, and the letters S. L. (seditious libeller) were branded on both cheeks. At the execution of this sentence in the palace yard a great crowd was present, which manifested its sympathy with the sufferer; and when he set out for his prison, Caernarvon castle, the road was lined with thousands of spectators, who were anxious for the honor of addressing him. Such numbers also visited the castle, that after a residence of 10 weeks he was removed by an illegal order to the castle of Mont Orgueil in the island of Jersey. There he remained till Nov. 7, 1640, when he was released by an order of the house of commons, his sentence being reversed, and damages to the amount of £5,000 being awarded him against his judges. His entrance into London had the appearance of a triumphal procession. Soon after he became a member of parliament for Newport in Cornwall, and in this position was employed to prepare the evidence against Laud. He took a prominent part in the proceedings of the long parliament, zealously espousing the cause of the Presbyterians, and opposing the Independents; and so little sympathy had he with the extreme measures then adopted, that he was taken into custody just before th king's trial for "denying the supremacy parliament," and on Dec. 6, 1648, was ej from the house. He now became a bitte ponent of Cromwell, and published artic so virulent a character that he was twice prisoned. He was one of the excluded m bers who sat in the house of commons ea 1660, and was so zealous in furthering the toration, that Monk sent for him and adv him to be quiet. After the restoration he appointed keeper of records in the to Wood, in his *Athenæ Oxonienses*, gives a c alogue of his writings, which comprises n 200 volumes. Of these the most valuab his "Collection of Records," "Calendar of P liamentary Writs," and "Observations on Fourth Part of Coke's Institutes." His w are described by Wood as "displaying g industry, but little judgment." His "Rec he intended to bring down as late as the r of Elizabeth, but he lived only long enoug complete the work as far as that of Henry I

PSALMANAZAR, George, the ass name of a French impostor, born about 1 died about 1753. His real name is unkn as also his early history. When first no he had wandered through a great part Europe, and the better to preserve his cognito gave himself out first as a Japan and afterward as a native of the islan Formosa. He travelled over various parts France, Germany, and the Netherlands a soldier, a beggar, a servant; and at l went to England with one Innes, a chapla a Scotch regiment. He now pretended t a convert to Christianity, and Innes obt promotion as the person influential in his c version. In 1704 he published at Londo pretended "History and Description of Island of Formosa, off the Coast of Chin The description of the island was given w such apparent fidelity, the manners and cus were illustrated with so many engravings, copious specimens were given of a new guage and character which bore critical exa nation, that the belief in the story was gen and the learned were divided in opinion the author repented of his evil courses and vealed the imposition. He now applied him seriously to study, and engaged in literary p suits. He wrote a large portion of the "U versal History," a true account as far as kno of Formosa for the "Complete System o Geography," and an "Essay on Miracles," made a version of the Psalms. He left b him in manuscript his own memoirs, wh were published in London in 1765.

PSALMODY (Gr. ψαλμωδια), a general te comprehending the art of writing or comp ing divine hymns or songs, but commonly stricted to metrical versions of the psalms David, to which simple and appropriate a are adapted. The practice of psalm singing Christians may be said to date from the la supper of Christ and his disciples, at the co usion of which they sang "an hymn or psalm" together; and during the apostolical age and for several centuries afterward it was a regular and important part of divine service, the performance being by the choir or the whole body of the church antiphonally. Gradually the part taken by the congregation became restricted, and finally, as a more scientific mode of singing came into vogue, trained performers monopolized the whole of the musical service of the church. At the period of the reformation the old practice was restored by Luther and Calvin, the former of whom may be considered one of the chief founders of modern psalmody, and metrical versions of the psalms were made in various languages. That in French of the first 50 psalms, by Clément Marot, proved exceedingly popular, and psalm singing became a fashionable amusement at the court of Francis I. This version was subsequently completed by Theodore Beza. The melodies were chiefly by Claude Goudimel and Claude de Jeune, native composers; but according to some authorities they were of German origin. Luther himself composed and adapted many psalm tunes, including the well known *Ein' feste Burg ist unser Gott*, versified from the 46th psalm; and his followers favored harmonized part singing, while the more severe Calvinists practised only a simple unaccompanied melody. About the time of Marot's publication appeared the English version of Sternhold and Hopkins, with music, original and selected from the Calvinistic school, and which, quaint and uncouth as it was, continued for many years to be that chiefly in use in England. Subsequently Thomas Ravenscroft, John Playford (called by Sir John Hawkins "the father of modern psalmody"), Dr. Croft, Handel, Dr. Miller, and others made valuable additions to English psalmody; and in 1696 the version of Tate and Brady took the place of that of Sternhold and Hopkins. Within the present century the number of psalm tunes has increased almost beyond calculation.

PSALMS, Book of, one of the canonical books of the Old Testament, containing a copious collection of religious songs. Religious poetry among the Hebrews, as among the oriental nations in general, can be traced to high antiquity. Even the Pentateuch contains several hymns and fragments of hymns, and in the book of Psalms we find one psalm which is ascribed to Moses. In the time of the Judges we meet with the beautiful song of Deborah (Judges v.), and the brief but equally beautiful song of Hannah (1 Sam. ii. 1-10). But the religious poetry of the Hebrews attained the highest degree of development through King David, who is recorded in the Scriptures to have practised it from early youth until his death, and in particular to have introduced the singing of hymns into the service in the tabernacle. In the Hebrew original 73 psalms are ascribed to David, but none of the old ecclesiastic translations, as the Septuagint, the Vulgate, and the Peshito, agrees in this respect. Beside Moses and David, several other authors of psalms are named in the headings; thus, 2 psalms are ascribed to Solomon, 12 to Asaph, 11 to the sons of Korah, a Levitic family, and one each to Heman and Ethan. The Alexandrine and the Syriac versions mention also the prophets Haggai and Zachariah as the authors of some psalms.—The collection of psalms, in the form in which it at present appears in the Old Testament, cannot have been completed until after the captivity, as some of the psalms are obviously of subsequent origin. But particular collections, which were afterward embodied in the book of Psalms, seem to have existed as early as the time of David. The book of Psalms is, according to the analogy of the Pentateuch, divided into 5 books, each of which closes with a doxology. The second book has moreover a postscript, which seems to have been the conclusion of an old particular collection. The Septuagint and the Vulgate, which follows it, differ somewhat from the Hebrew in numbering the psalms, the difference beginning with the 10th and extending to the 147th; the entire number in all these is 150.—The contents of the book of Psalms are manifold. With regard to their object, they may be divided into 6 classes: 1, hymns to God, in which he is praised as the creator, preserver, and governor of the world, and in particular as the protector of his chosen people; 2, national psalms, in which the people are reminded of the ancient history of Israel since the time of the patriarchs, especially of the history of Moses, of the many favors received from God, of the occupation of the promised land, of the signal assistance of God, and of the gratitude therefore due to him; 3, the king's psalms, in which the theocratic king is praised as the representative of Jehovah, and the assistance of the Lord is invoked for him; 4, moral hymns, in which the fate of the pious and the wicked is described; 5, the psalms of lamentation, in which, sometimes by individual Israelites, sometimes by the entire people, misery and calamity, especially oppression experienced from foreign or domestic foes, are lamented, with a prayer to God for deliverance; a subdivision of this class are the penitential psalms, describing the sufferings of the psalmist as deserved, recognizing the committed sin, and praying for pardon; 6, prophetic or Messianic psalms, which have reference to the Messiah and to the extension of his kingdom. There prevails among exegetical writers a great difference of opinion as to the number of psalms belonging to this last class, and theologians of the rationalistic school have even maintained that a directly predictive character cannot be claimed for a single passage in the psalms.—The collection of psalms seems to have come at once into public use at divine service both as prayers and hymns. The singers who were appointed by David for the service of the sanctuary sang psalms, which were without doubt mostly psalms of David. In the time of Hezekiah, psalms of David and Asaph were sung at religious solemnities (2 Chron. xxix. 30), and the same is recorded to have taken place in the second temple after the captivity (Ezra iii. 10). In the Christian church the book of Psalms had likewise from the beginning a great importance. Christ himself, after the celebration of the last supper, sang psalms with his disciples; and soon after, when on the cross, he used the words of a psalm to express his being abandoned by the Father. After his resurrection he expressly declared that the psalms contained prophecies pointing to him. Paul and Silas praised God in psalms in the dungeon at Philippi, and Paul exhorts the Ephesians and Philippians to praise the Lord with psalms and spiritual songs. The early Christians used the psalms both in public service and in their private devotions, and the church soon made them a prominent part of the liturgical books, in particular of the breviary. In the Protestant churches the psalms have always been extensively used for congregational singing, and some denominations, as the Reformed Presbyterian church, do not allow in divine service the use of any other religious hymns.—On account of the significance which has always been attached to the book of Psalms, it has in modern times called forth a larger number of commentaries than any other biblical book. Le Long, in his *Bibliotheca Sacra* (Paris, 1723), enumerates, more than 500 commentaries, exclusive of those which form parts of larger works, as well as of the commentaries on a part of the book of Psalms. Among the English commentaries the work of Bishop Horne has not yet been superseded for popular use, though its critical value is small. The recent literature of England contains no original work of prominence, and a thoroughly good commentary is still felt to be a great desideratum. The recent exegetical literature of Germany is rich in excellent commentaries, among which those by De Wette, Hitzig, Hirzel, Ewald, Hengstenberg, Delitzsch (2 vols., Leipsic, 1860), and Hupfeld (4 vols., Gotha, 1859–'61) are best known. Among recent Roman Catholic commentaries, that by Schegg is particularly valued. In America new translations have been published by Drs. G. R. Noyes and Joseph A. Alexander, the latter with a commentary based on that of Hengstenberg.

PSALTERY, a stringed musical instrument in use among the ancient Jews, and supposed to have been identical with the *nebel* mentioned in the Psalms. Burney says it resembled partly the lyre and partly the harp, but according to other authorities it was in shape a trapezium, not unlike the instrument known as the dulcimer. (See DULCIMER.)

PSEUDOMORPH (Gr. ψευδης, false, and μορφη, form), in mineralogy, a crystal having a form belonging to some other mineral species. In the changes which are ever going on in minerals and rocks, the constituents of crystals are frequently removed and replaced or otherwise altered, and present new combinations without any accompanying change in the original form. This occurs in various ways, as by the displacement of a soluble salt and the subsequent filling of the vacant mould by the introduction of another mineral substance, as in the case of a cubic crystal of common salt in clay, removed by water, and the place afterward filled by gypsum; and again by incrustation of some foreign mineral substance over the original crystal, which may be subsequently dissolved away, leaving the hollow shell empty, or this may be again filled by infiltration of some mineral substance. Such changes are chiefly mechanical; but others are recorded of more decidedly chemical nature, as when interchange of elements goes on *pari passu* when new compounds are produced by the removal or addition of one or more elements. The range in which these changes may occur is so extensive, that there result a multitude of minerals in shapes entirely strange to their composition, and often on this account perplexing to recognize. In general such crystals may be suspected by their lack of lustre and sharp well defined angles of the genuine crystal. Their structure also is [illegible] granular; and if they have any cleavage, this is in quite a different direction from that belonging to the original mineral. Among the great variety of pseudomorphs the following are of frequent occurrence: pyroxene minerals and other silicates converted into steatite; iron pyrites and various other species into hematite; fluor spar and many others into quartz, &c. In geology the common examples of metamorphism may be regarded but as cases of pseudomorphism carried out upon a large scale, and the altered crystals wherever met with possess a new signification as types and evidences of vast changes and processes of the decay and reformation in inorganic nature. The subject was first systematically treated by Haidinger in Brewster's "Edinburgh Journal," vols. ix. and x., and afterward in the work specially devoted to the subject by Dr. J. R. Blum, entitled *Die Pseudomorphosen des Mineral*[illegible] (Stuttgart, 1843). It is also discussed by [illegible] schof and Volger in their works, and elaborate papers upon the subject by Prof. James [illegible] Dana are contained in the "American Journal of Science" (1st series, vol. xlviii., 1845).

PSKOV, or PLESKOV, a W. government of European Russia, bounded N. by St. Petersburg, N. E. by Novgorod, E. by Tver, S. E. by Smolensk, S. and S. W. by Vitebsk, and W. by Livonia; area, 16,588 sq. m.; pop. in 1856, 696,9[illegible] The most important towns are Pskov and T[illegible]ropetz. The Valdai hills traverse the S. E. part, but the surface is generally level. There are several lakes, the most important of which, Lake Pskov, or the southern part of Lake Peipus, comes within the limits of the province on the N. W. frontier; and in the S. E. there are numerous marshes. A great part of the country covered with forests. The principal crops ed are rye, oats, barley, and pulse. Hemp flax are cultivated. The only manufacture any importance is leather, and the inhabi- ts excel greatly in dressing skins. The pop- tion is chiefly of Russian origin, but there a few of other races, including some Moham- dans. In 1854 the government contained village schools, attended by 806 pupils.—ov, the capital, is situated on the left bank he Velikaia, about 5 m. from its mouth in e Pskov, and 165 m. S. S. W. from St. Peters- g; pop. 19,842. It is enclosed by a wall in circuit, and the Kremlin, or citadel, ds in the centre. There are a cathedral about 50 other churches, several of which in a ruinous condition, 3 convents, several ols, and some charitable institutions. Pskov ery conspicuous in the early history of Rus- It has been often besieged; in 1614 Gus- s Adolphus was obliged to retire from re its walls.

SYCHE (Gr. ψυχή, breath, or the soul), a racter of Greek romance, generally accepted personification of the human soul. Her y is thus told by Apuleius. A certain king 3 daughters, of whom the youngest, ed Psyche, was a marvel of beauty, and rs were consecrated to her that properly nged to Venus. The anger of that goddess excited, and she commanded her son Cu- to inspire Psyche with a passion for some itful monster; but he himself fell in love her, and bore her away to a delightful e, where she was visited every night by young god, who left her at dawn. Her ers persuaded her that he who came to her y night, and whom she had never seen, t be some loathsome creature, and urged to destroy him while he slept; but when brought a lamp and beheld his beauty, her deprived her of the power of motion, and le she stood a drop of hot oil falling from lamp upon his shoulder awoke him. With w words of reproach he fled. Psyche now eavored to destroy herself, but nothing in ure would injure her. At length, through contrivance of Venus, she fell under the ence of a sleep brought especially from infernal world. From this sleep she was aroused until Cupid came and touched her h the point of one of his arrows, when she e, and, being now sufficiently purified ugh suffering, was united to her beloved Love himself.

SYCHOLOGY. See PHILOSOPHY.

TARMIGAN, the popular name of the gal- naceous birds of the grouse family embraced he genus *lagopus* (Briss.), which differ from ordinary grouse in having the legs feather- o the claws, giving somewhat the appear- e of a hare's foot (whence the generic name, λαγώς, a hare, and πούς, foot), in the trun- d tail about ⅔ as long as the wings and of o 18 feathers, in most of the species becom- white in winter, and in the nasal groove being densely clothed with feathers; the family characters have been given under GROUSE. There are 6 or 8 species described, inhabiting the northern and snow-covered regions of both hemispheres, being one of the few genera characteristic of the arctic fauna; they are as much at home in snow as are the web-footed birds in water, and their plumed feet enable them to run over its surface without sinking in. They live in families during most of the year, and are monogamous; the females incubate, but the males assist in rearing and feeding the young; the males have a loud harsh cry, and the females cackle like a hen. They are rapid fliers and without a whirring noise, and swift runners; they feed upon berries, buds, mosses and lichens, and even insects; their flesh is good, and their pursuit affords an exciting sport; they are very shy, but when started are easily shot on account of their regular flight. The summer plumage is varied with brown, black, and gray, most of the wing remaining white; in the males the mottling is finer and the colors brighter. It is very difficult to ascertain the exact number of species, from the rarity of specimens in summer plumage, and the absence of accurate determination of sex.—There are 3 well ascertained species in America. The white ptarmigan or willow grouse (*L. albus*, Aud.) is about 15½ inches long and 24½ inches in alar extent; the bill is black, very stout and convex, and broad at tip; the general plumage in summer is rufous or orange chestnut on the head and neck; feathers of back black, closely barred with yellowish brown and chestnut; most of wings and lower parts white; tail brownish black; in winter white, with black tail; no black stripe through the eye. It occurs in the northern parts of America, and is common in eastern Labrador, Newfoundland, and the Hudson's bay territory, and in rare instances in the northern United States; it is found in open rocky grounds and among dwarf willows and birches. In winter they scratch in the snow down to the mosses and lichens on which they feed, collecting often in considerable flocks; in winter the flesh is dry, but is tender and with an agreeable aromatic flavor in summer. They breed in Labrador about the beginning of June, placing the nest under the creeping branches of low firs; the eggs are from 6 to 14, of a fawn color or rufous ground with irregular spots of reddish brown; only one brood is raised in a season. The rock ptarmigan (*L. rupestris*, Leach) is 14½ inches long; the bill is slender, rather compressed at tip; in summer the feathers of the back are black banded with yellowish brown and tipped with white; in winter white, with the tail black (the 4 middle feathers white), and the male with a black bar from the bill through the eyes. It occurs in arctic America, rarely coming further south than lat. 62° N. in the interior, but to 58° on Hudson's bay, and in the Rocky mountains, according to Richardson, in 55°; the same species is said to occur in the northern parts of the eastern hemisphere;

the eggs are pale reddish brown, with darker spots, and are 1⅝ by 1¼ inches. The white-tailed ptarmigan (*L. leucurus*, Swains.) has a slender bill, the plumage in summer blackish brown barred with brownish yellow, and in winter entirely white; it is 13 inches long and 21 in alar extent; it is found in the N. W. portions of America, and to the south along the Rocky mountains to lat 39°.—The common European ptarmigan (*L. mutus*, Leach) is about 15 inches long; the bill is black, short, and robust; the summer plumage is ashy brown mottled with darker spots and barred with orange yellow and dark brown on the sides of the neck and back, and the tail, with the exception of the 2 middle feathers, grayish white with a narrow terminal white band. It is fond of lofty and northern regions, going as far as Greenland and coming down to the highlands of Scotland; when pursued, like the other species, it is apt to dive under the soft snow; it sometimes does this for protection from the cold, and in damp weather is sometimes imprisoned and destroyed under the frozen surface of the snow; the ruffed grouse has the same habit. A species much resembling this, if not identical with it, occurs in America, in the neighborhood of Baffin's bay, and has been described by Audubon as *L. Americanus*.—The Scotch ptarmigan or moorcock (*L. Scoticus*, Steph.) seems peculiar to Great Britain, and is abundant in the hilly districts of Scotland; the general color is chestnut brown, with black spots on the back and undulating black lines below; the winter plumage is the same. It is much esteemed as game, being to the fowler what the fox is to the hunter or the salmon to the angler; where not much pursued it is not very shy, but its plumage is so like the surrounding dark moss and heaths, that it is almost impossible to discover it without the aid of a pointer; it feeds upon heath tops and mountain berries.

PTERICHTHYS, a remarkable fossil fish. See GANOIDS.

PTERODACTYL (*pterodactylus*, Cuv.; Gr. πτερον, wing, and δακτυλος, finger), a remarkable genus of fossil flying reptiles, possessing essentially the characters of saurians, with some only apparent relations to bats and birds. They have been divided into 3 genera according to the number of joints in the wing-bearing finger and the disposition of the teeth; all are characteristic of the secondary epoch, being found principally in the lithographic schists of Solenhofen, and in the oolite, lias, wealden, and chalk of Europe. In the genus *pterodactylus* the jaws had teeth even to the extremity; the skull was elongated, with the intermaxillaries large; nasal opening wide and near the middle of the muzzle, partly closed in front by a small bone as in the monitors, and with a surrounding circle of small bones and a small opening into the orbit as in birds; the lower jaw, as in crocodiles, had no coronary process, and was articulated behind the eyes; the teeth, 5 to 17 on each side, were conical, slightly arched, compressed, inserted in separate cavities, and lowed at the base; neck of 7 stout verte dorsals 13 to 15, and, with the ribs, we lumbar 2 or 3, sacral 6, anchylosed toge and caudal 10 to 15; the shoulder blade coracoid bone separate and weak; sca arch and pelvis as in lizards, except the last seems to have had marsupial bones, ac ing to Pictet; the long bones hollow and air openings, as in birds; humerus short stout, and forearm twice as long; hind slender, with 5 moderate toes of the length; 5 or 6 bones in the wrist, 5 me pals, 5 fingers, with respectively 1, 2, 3, 4 4 joints; the first 4 short and with h nails, the external very long, equal to the and body, and nailless; the gape of very large. This singular animal was ref to the swimming birds by Blumenbach, a the bats by Sömmering, and was determin be a reptile by Cuvier. The nearly equ conical teeth, very small cranial cavity, ent number of joints in the fingers, and ian shape of sternum and scapula, show t was not a bat-like mammal; the very exis of teeth, the small number of the verteb the neck, the thinness of the ribs and tail an absence of recurrent processes in the latte form of the sternum and number of the fin prove that it was not a bird. These chara place it among reptiles, but it had also a m fication of the anterior extremities in the of wings, which are not possessed by an isting or any other fossil members of the the so called wings of the dragon being me membranous expansions from the sides of body supported by the ribs. The form of wings is also remarkable and unique; in the fingers are very little separated, and as a basis for the plumes; in bats the membrane is stretched upon the 4 elong fingers, the thumb remaining rudiment but in the pterodactyl the external finger is greatly developed and supports the membrane, the other 4 having the usual dimensions; the membrane extended prob from the long finger along the sides of the to the hind limbs and beyond, including tail. About 20 species are described, vary in alar extent from a few inches to 4 or 5 ya they probably flew and crept about in the manner of bats; the form of the teeth and stren of the jaws indicate a carnivorous animal of feeble powers; the smaller species must h been insectivorous, and the largest may ha seized fish or small reptiles of their own other genera. The great size of the eyes in cates nocturnal habits; the posterior lim were so far developed that they could doubtl assume an erect position like birds, and pe on trees; the claws of the fore and hind would also enable them to climb along rocks; the body was probably more or le scaly, as in lizards. From the weakness of scapular arch some have doubted the power active flight in the pterodactyl, believing

e wing membranes could only support it in
e air when leaping from place to place, in a
tle more perfect manner than in the dragons;
ut it must be remembered that the atmosphere
the secondary geological age contained more
rbon and less oxygen than at present, and
at in a dense medium, approaching more
arly the physical properties of water, even a
ld-blooded reptile might rise on the wing,
d fly heavily through the thicker air, with
e necessary expenditure of much less muscular
ergy than is now requisite for aërial locomo-
on.—The most anciently known species is the
. longirostris (Oken), about the size of a
oodcock, with a length of 10 inches and an
ar extent of 21; the teeth were $\frac{11}{11}$ on each
de. The *P. crassirostris* (Goldf.), with a
rger head and shorter neck, was a foot long
nd 3 feet in alar extent, and the teeth [illegible]. The
. brevirostris (Cuv.) had a shorter muzzle, the
ead resembling more that of a goose just
atched than of a reptile; the teeth were very
mall, [illegible]; the total length was less than 8 inches,
nd there were only 4 posterior toes. Other
pecies were less than 2 inches long, while on
e contrary the *P. ornis* (Giebel) of the wealden
as 2 feet in length; in the chalk of Maidstone,
ngland, Mr. Bowerbank detected bones of a
pecies which he named *P. giganteus*, 6 to 7
et in alar extent; the *P. Cuvieri* (Bowerb.)
believed to have spread 16½ feet.—The genus
amphorhynchus (H. de Meyer) or *ornithocepha-*
s (Sömm.) was separated for a few species of
e Jurassic age, having the anterior portion of
e jaws without teeth, and probably with a
orny beak; the scapula and coracoid were
nsolidated together, and the tail long and stiff,
ith about 30 vertebræ; there were 4 joints in
e wing finger; the largest species was about
8 inches long. In the genus *ornithopterus* (H.
e Meyer) there were only 2 joints in the wing
nger.—It will be seen from the above descrip-
ion that the pterodactyl was most unlike any
hing now living, and presented a union of
range and seemingly incompatible characters,
aralleled only in the uncouth and impossible
reations of Chinese imagination.

PTOLEMAIS. See Acre, St. Jean d'.

PTOLEMY I. (Ptolemæus), surnamed Soter,
on of Lagus, founder of the Græco-Egyptian
ynasty, born near the court of Philip of Mace-
on in 367 B. C., died in Alexandria in 283.
He was one of the generals of Alexander the
reat, and rendered important services to that
onqueror in his Asiatic campaigns. In the
ivision of the empire which followed Alex-
nder's death, in 323, he became ruler of Egypt,
hich remained nominally a satrapy of Mace-
on under the regency of Perdiccas. Hasten-
ng to Alexandria, he put to death Cleomenes,
lexander's satrap, on the pretext of his being
partisan of Perdiccas. This gave him pos-
ession of a large sum of money which Cleo-
menes had extorted from the Egyptians, and
ith this treasure he equipped an army and
ook Cyrene. To oppose the ambitious schemes
of Perdiccas, he leagued in 321 with Antigonus, Antipater, and Craterus. Perdiccas invaded Egypt, but penetrated no further than the Nile, where Ptolemy had so strongly fortified himself that he foiled Perdiccas in every attempt to cross. On hearing of the assassination of his rival by his mutinous soldiers, he sent wine and provisions to the invading army, and so won them by his courtesy that they unanimously offered him the regency, but he declined it. The next year he seized upon Phœnicia and Cœle-Syria. It was probably during this expedition that he took possession of Jerusalem without opposition by attacking it on the sabbath day. To resist Antigonus, who had now become the most powerful of Alexander's successors, he formed a coalition in 316 with Seleucus, Cassander, and Lysimachus; and after a vehement struggle of 4 years, during which he lost Phœnicia, a hollow peace was concluded (311). The next year Ptolemy renewed hostilities under the pretext that Antigonus had violated the treaty by keeping his garrisons in the Greek cities of Asia Minor and the adjacent islands, and in the course of the long war which followed he lost Cyprus by his defeat in the memorable sea fight near Salamis in 306. Antigonus, elated by this great victory, assumed the title of king, and Ptolemy followed his example. Demetrius, the son of Antigonus and conqueror of Salamis, now invaded Egypt, but, baffled at the banks of the Nile, turned his arms against Rhodes, which had refused to join in the attack. Ptolemy however enabled it to hold out by furnishing repeated supplies of troops and provisions, and out of gratitude for their preservation the Rhodians paid him divine honors, saluting him with the title of saviour (Soter). The death of Antigonus at the battle of Ipsus in 301 terminated the war, and added Syria and Palestine to Ptolemy's dominions; and in 295 Cyprus was again and finally brought under Egyptian sway. The rest of his reign was peaceful. He took wise and vigorous measures to promote the happiness of his Egyptian subjects, revived their ancient religious and political constitution, restored to the priestly caste some of its former privileges, and fixed his capital at Memphis. To the Jews also and the Greeks the same toleration was shown, and great numbers of them were attracted to Alexandria by Ptolemy's enlightened and peaceful policy. He created literary institutions which reached their greatest splendor under his successor, Philadelphus. The most celebrated of these were a library and a museum, a kind of university whose professors and teachers were supported at the public expense. Ptolemy cultivated letters as well as patronized them, and wrote a history of the wars of Alexander, which was praised. He wished his youngest son Philadelphus, the offspring of his favorite wife Berenice, to succeed him, to the exclusion of his older son by his former wife Eurydice. This exciting violent opposition at court, he consummated his purpose by

a voluntary abdication in favor of Philadelphus in 285. He continued however to exercise sovereignty until his death.

PTOLEMY II., surnamed PHILADELPHUS (lover of his brother), king of Egypt, youngest son of the preceding by Berenice, born in the island of Cos in 309 B. C., died in Alexandria in 247. His father caused his accession in 285 to be celebrated with great pomp. He had grown up in a period of public peace and tranquillity, had been carefully educated in elegant learning, and came to the throne thoroughly imbued with his father's enlightened policy. He cleared upper Egypt of robbers, and penetrated Ethiopia on scientific explorations and ostrich and elephant hunts, establishing traffic with the barbarous tribes. Southern Africa also he opened to the enterprise of the Alexandrian merchants. To command the Red sea he founded Arsinoë (near Suez), and connected it with Alexandria by restoring and completing the canal begun by Necho. Lower down he constructed the ports of Myos-Hormos and Berenice, and connected the latter with Coptos on the Nile by an artificial road 258 miles long across the desert. This road continued for ages the route of merchandise from the east and south to Alexandria. Philadelphus was most celebrated as a munificent patron of learning. Under his care the institutions his father had founded attained the highest prosperity. (See ALEXANDRIAN LIBRARY.) The museum included botanical and zoological gardens, and the study of natural history was prosecuted with great ardor and success. This study he further fostered by establishing menageries of wild and rare animals. He sent agents through Greece for the collection of works of art, and made large additions to the literary treasures of the library. He spent vast sums of money on public works, built the celebrated lighthouse on the island of Pharos, and erected a magnificent royal mausoleum to which he removed the remains of Alexander from their resting place at Memphis. The most distinguished poets, philosophers, mathematicians, and astronomers of that time adorned his capital. For the use of the Alexandrian Jews, the Septuagint version of the Hebrew Scriptures is said to have been made by his command. The quiet of his reign was early disturbed by the revolt of his half brother Magas, viceroy of Cyrene, who succeeded in maintaining his independence; and by a contest for the possession of Phœnicia and Cœle-Syria, which was kept up at intervals to near the close of his life, when these provinces at last remained in his possession. He took part at different times in the affairs of Greece, maintaining an unfriendly attitude toward Macedon, and established relations of amity with the rising republic of Rome. He founded a gymnasium at Athens, and planted numerous colonies in various parts of his foreign dominions, which comprised Phœnicia, Cœle-Syria, Palestine, Cyprus, Lycia, Caria, the Cyclades, and portions of Ethiopia, Arabia, and Libya. The effeminacy of the court increasing with the wealth of the country, and being himself of delicate constitution, he came at length to lead the indolent life of a refined voluptuary. Military discipline was neglected, though the number of his war ships was immense. Repudiating his first wife, he married his sister Arsinoë, which the Egyptian law allowed, but she brought him no children. Another stain on his memory is the execution of two of his brothers, in derision for which his surname is said by some to have been bestowed upon him.

PTOLEMY III., surnamed EUERGETES, eldest son and successor of the preceding, by Arsinoë, daughter of Lysimachus, died in 222 B. C. On coming to the throne he found in the public treasury an immense amount of money, and at his command a vast army and navy. His warlike ardor was roused by the ill treatment and subsequent murder of his sister Berenice, wife of Antiochus Theos, king of Syria. With a large army he ravaged Syria and the eastern provinces, advancing as far as Susa, and, without establishing his authority in any new possessions, brought back immense booty in gold and silver, among which were the Egyptian idols which Cambyses had carried off to Persia. This conduct the Egyptians esteemed so meritorious that they called him Euergetes (benefactor). In right of his wife Berenice, daughter of Magas, Cyrene was united to his hereditary dominions, and he made large acquisitions of territory in Arabia and Abyssinia. He inherited the religious liberality and love of learning of his progenitors, and was like his father a proficient in letters. He enlarged the museum, entertained men of learning at his court, and fostered trade, so that under him Alexandria continued her career of unexampled prosperity. The wealth of the empire is shown by the magnificent presents he bestowed upon the Rhodians when their city was destroyed by an earthquake toward the close of his reign. It is commonly reported that he was murdered by his son and successor Ptolemy Philopator, though Polybius asserts that he died a natural death.

PTOLEMY, CLAUDIUS, an Egyptian mathematician, astronomer, and geographer, said to have been born in Pelusium, flourished at Alexandria in the reigns of Hadrian and Antoninus. Scarcely any particulars of his life are known. He handed down to posterity, in the Μεγάλη Συνταξις, or "Great Construction" (of the heavens), the only record we have of the astronomical observations and theories of the ancients who dwelt around the Mediterranean. The most important part of this work is a catalogue of stars, the oldest extant, which is doubtless that constructed by Hipparchus, reduced by Ptolemy to the first year of the reign of Antoninus Pius (A. D. 138). The work treats of the relations of the earth and heavens; the effect of position upon the earth; the theory of the sun and moon, without which that of the stars can-

t be undertaken; the sphere of the fixed stars,
d the determination of the planetary orbits.
olemy adopted the system which places the
rth in the centre of the universe. This theo-
y known by his name, was universally receiv-
till the time of Copernicus. During all that
terval, the history of astronomy presents
arcely any thing more than comments on his
ritings. But for the Arabians the *Syntaxis*
ould doubtless have perished. It was trans-
ted by them, and handed down under the
tle of *Almagest*, in the reign of the caliph Al-
amoun (about 827), son of Haroun al Rashid.
tolemy left a very copious account of the
anner in which Hipparchus established the
ain parts of his theories, and in most of the
anches of the subject gave additional exact-
ss to what that astronomer had done. He
omputed, notwithstanding the fundamental
rors and the inaccuracies of his system, the
lipses of the next 6 centuries; determined the
anetary orbits; and discovered the moon's
econd inequality or evection. As a geometer he
as been ranked as certainly the fourth among
e ancients, after Euclid, Apollonius, and Ar-
himedes. In physics he made an important
dvance. He experimented with a ray of light,
ausing it to pass through media of unequal
ensity, and thus discovered refraction, and has
ccordingly been regarded as the founder of an
mportant branch of the science of optics. He
rst recognized the alteration of the apparent
osition of a heavenly body which is due to this
ause. Ptolemy wrote a universal geography,
hich Humboldt describes as a "colossal" pro-
uction; and the same authority speaks of his
eographical information as surpassing that of
trabo. He was the first to use the terms lati-
ude and longitude, by which he laid down the
osition of each country and town. He proved
he earth to be a globe, and calculated its in-
abited parts to extend from the meridian of
Thinæ, long. 119° 30' E. of Alexandria, to the
eridian of the Islands of the Blessed, 60° 30'
W.; and from the parallel of Meroë, about lat.
16° 30' N., to that of Thule (Iceland or the
Shetland islands), 63° N. After him no one
attempted for many centuries to reform geog-
raphy except in the improvement of details,
and his great work continued to be the stand-
ard text book till the 16th century. He was
distinguished also as a musician, and wrote
treatises on music, mechanics, chronology, and
astrology.

PUBERTY, the period of youth character-
ized by the acquirement of functional power in
the reproductive apparatus of both sexes; its ac-
tivity, however, cannot be called into exercise
until the growth of the individual is completed,
on penalty of premature and permanent ex-
haustion of the vital powers, and the develop-
ment of any latent disposition to disease. That
puberty is not the period of completed growth
is shown by the increase in stature after its
attainment, the subsequent ossification of the
vertebral spinous and transverse processes, and
the consolidation of the pelvic, sacral, and coccygeal vertebræ, sternal pieces, and epiphyses of the ribs, scapula, clavicle, and bones of the extremities. In the human male puberty is established between the 14th and 16th years; beside the increased sexual and muscular development, the beard makes its appearance, the larynx enlarges, giving a lower, harsher, and stronger tone to the voice, and the thoughts, desires, and actions have a more manly character. In the female this period is arrived at between the 12th and 16th years in temperate climates, and somewhat earlier in the tropics and in the midst of the luxury and excitements of city life; there is a similar development in the reproductive system, usually coincident with the appearance of the catamenia and mammary enlargement, and a deposition of fat over the whole surface of the body, causing plumpness and roundness. In the male there is at this time no special tendency to disease, nor in the healthy female; but, as a consequence of the defective physical training of most female youth, disorders of the menstrual function are very apt to occur, with numerous functional, nervous, and even organic complications; in persons of naturally weak constitutions, of both sexes, and in those enfeebled by premature exercise of the mental, physical, or generative powers, the tuberculous diathesis is frequently developed in the lungs soon after puberty.

PUBLICOLA, Publius Valerius, a Roman general and lawgiver, who flourished at the beginning of the republic. His original name was Publius Valerius. According to the common story, he was present when Lucretia stabbed herself, and bore a prominent part in the expulsion of the Tarquins, and after the compulsory resignation of Collatinus was elected consul in his place. In the war between the Tarquins and Veientes and the Romans, he gained a victory over the former in 509 B. C. Returning to Rome, he began building a house on the Velian hill overlooking the forum, which excited fear in the people that he was seeking to raise himself to royal power. When Valerius discovered the existence of these suspicions, he ordered the building to be demolished, and his lictors when they appeared before the people to lower their fasces; whence he received the surname of Publicola or Poplicola, "the people's friend." He now brought forward laws for the establishment of the republic, one of which declared that whoever attempted to make himself king might be killed by any one; another that plebeians condemned by a magistrate should have the right of appeal to the people. He was afterward thrice elected consul; and the expedition of Porsena is placed during his time of office. In 504 he and his colleague, T. Lucretius Tricipitinus, routed the Sabines and returned to Rome in triumph. The annalists usually placed his death in the next year, although Niebuhr thinks that in the original legend he perished at the battle of the lake Regillus in 495 or 496 B. C.

PUBLIUS SYRUS, a Latin comic poet, who flourished at Rome about 42 B. C. He was a native of Syria, and was brought to Rome as a slave; but his sprightliness and wit excited the admiration of his master, who had him well instructed and gave him his freedom. Previous to Publius the mime had consisted to a greater extent of grimace and gesture, and was nearer to what is now known as pantomime; but he interspersed it with proverbial sayings and moral sentences. It is said by St. Jerome that a collection of moral sentences from the farces of Publius was a school book at Rome.

PUCHTA, Wolfgang Heinrich, a German jurist, born in Mährendorf near Erlangen, Aug. 8, 1769, died in the latter city, March 6, 1845. He was originally an advocate, and, after having been employed in various civil offices, was in 1811 made director of the general court of justice in Erlangen. He wrote a large number of works on legal subjects, and in 1842 embodied the results of his experience in a work entitled *Erinnerungen aus dem Leben und Wirken eines alten Beamten*.—**Georg Friedrich**, son of the preceding, born in Cadolzburg, Franconia, Aug. 31, 1798, died Jan. 8, 1846. He was educated at Erlangen, and from 1820 to 1842 was successively teacher in that city, Munich, Marburg, and Leipsic. In the latter year he went to Berlin as Savigny's successor, and was there made member of the state council, and of the legislative commission. His writings are chiefly expositions of the Roman and the canon law.

PÜCKLER-MUSKAU, Hermann Ludwig Heinrich, prince of, a German traveller and author, born at Muskau, Saxony, Oct. 30, 1785. He studied law at Leipsic from 1800 until 1803; entered the king of Saxony's body guard, joined the Russian army in 1813, and served as aide-de-camp to Prince Augustus of Saxe-Weimar; distinguished himself in the Netherlands, was made lieutenant-colonel and military governor of Bruges, and in 1822 was created a prince by the king of Prussia. He travelled in France and England in 1828, in the north of Asia and in Africa in 1835, and subsequently in Italy and the other countries of Europe. He has published various books of a lively and entertaining character; among them his letters from England, translated under the title, "The Tour of a German Prince" (3 vols., London, 1831), excited much attention from its familiar pictures and revelations of aristocratic life.

PUDDLING. See Iron Manufacture, vol. ix. p. 604.

PUEBLA, La, or La Puebla de los Angeles, a S. state of the Mexican confederation, bounded N. and E. by Vera Cruz, S. by Oajaca and Guerrero, and W. by Mexico; area, 8,581 sq. m.; pop. in 1857, 655,622. The drainage belongs partly to the gulf of Mexico and partly to the Pacific, but there are no large rivers. The state is intersected from N. W. to S. E. by the Cordillera of Anahuac, of which Popocatepetl, a volcanic mountain, 17,716 feet above the sea, is the highest point in North America. The most valuable mineral productions are silver and marble. The general elevation of the surface is about 6,000 feet, and a great deal of the soil is fertile, producing abundant crops of different kinds of grain, fruit, cotton, sugar, &c. The principal manufactures are glass, soap, iron, steel, and earthenware; and there is some trade carried on both with the coast of the gulf of Mexico and that of the Pacific, as well as with other parts of Mexico. Many remarkable remains of ancient Mexican civilization are found in this state.—PUEBLA, the capital, is situated 7,881 feet above the sea, 76 m. E. S. E. from Mexico; pop. 75,000. The streets are well laid out, with many fine squares. There are 72 religious edifices. The interior of the cathedral, which forms one side of the principal square, is rich in gold and silver ornaments, paintings, statues, &c. Several of the other churches are handsome buildings, and are also richly decorated. There are numerous convents, colleges, academies, charity schools for both boys and girls, hospitals, and other benevolent institutions. The bishop's palace has a library with a tolerably extensive collection of Spanish and French books. Many of the inhabitants are wealthy, but the people generally are said to be the most demoralized in Mexico. The city is well supplied with water by a small stream on its E. side, and the climate is particularly mild and agreeable. The manufactures include glass, earthenware, soap, sword blades, and coarse woollen cloth; some trade is carried on, and the market is well supplied with all kinds of provisions except fish. Puebla is the second city in the Mexican confederation.

PUEBLO INDIANS, the name applied to several tribes of semi-civilized Indians within the limits of New Mexico, so called by the Spaniards from their living in *pueblos* or villages. They have many characteristics in common which distinguish them from the nomadic tribes, as well as from that most degraded family known as the Digger Indians, who live upon roots, seeds, fish, reptiles, and such other food as they can secure without labor. The Pueblo Indians cultivate the soil, raising generally maize, wheat, and other cereals, vegetables and fruits, and in a few instances cotton. They also raise considerable herds of cattle, mules, horses, goats, and sheep. They spin and weave cotton and wool, and make heavy blankets, sometimes of a superior texture resembling the *serapés* of the Mexicans, and commanding from $30 to $50 each when sold to the Americans. They also make a superior kind of pottery, of various colors, and generally ornamented with geometrical figures. They live invariably in communities and towns. Their houses are sometimes built of stone laid in mortar made of mud, but more generally of sun-dried brick, or *adobe*, the common building material of northern Mexico. These buildings are generally arge, of several stories, and contain many families. In some of the pueblos the whole community, amounting to from 300 to 700 souls, are domiciled in one of these huge structures. The houses are sometimes built in the form of a hollow square; at other times they are constructed on the brow of a high bluff, or mountain terrace, difficult of approach. The first or lower story is invariably without doors or other openings, entrance to the house being effected by ladders. Each upper story recedes a few feet from that below it, leaving a terrace or walk around or along the whole extent of the structure, from which ladders lead to those above. The upper stories have doors and windows, but no stairways. In most instances a single family occupies one apartment, and as its number increases another apartment is added when there is sufficient space, or it is built above and reached by a ladder. In this way these structures sometimes reach 5 or 6 stories in height. This mode was practised by these Indians 3 centuries ago, when the country was first visited by the Spaniards. In every village there is at least one large room, sufficiently capacious to contain several hundred persons, in which they hold their councils and have their dances. These dances are of various kinds, and are more or less connected with their superstitions. Among those strictly so are the dances of the turtle, of good fortune, and one called *cachina* which is usually practised in the winter. The second they dance at their festivals before certain idols which they call the gods of fortune. The superstitious rites connected with their wars are peculiar. Whenever an enemy is killed, they cut off his long hair, drink his blood, and bedaub their faces and garments with it. They then wet their hands with it, particularly the right one, until they are thoroughly soaked, in the belief that by this practice they will increase their strength and raise their animal spirits. To complete the ceremony, they place the scalp of the enemy in the hands of the one who first took it, whom they call the *matador*, or killer. This man is ever afterward regarded with great distinction, even though he may not have been present when the prisoner's life was taken.—The following table of the names and population of the Pueblo Indians is from the return of the census of 1851:

Taos	361	Acoma	350
Picuris	222	Jemez	365
San Juan	568	Isleta	751
Santa Clara	279	Sandia	241
San Ildefonso	139	Cia	124
Pojuaque	48	Santa Ana	399
Tesuque	119	[illegible]	[illegible]
Nambe	111	San Felipe	411
Zuñi	1,294	Santo Domingo	666
Laguna	749	Cochiti	254

Total 7,867

The 7 villages of the Moquis (estimate of Dr. Ten Broeck in 1852) 5,000

To these may be added the Pimos and Coco-maricopas of the Gila, whose numbers may be estimated at .. 4,000

Total of Pueblo and agricultural Indians 16,867

The last two are not usually classed among the Pueblo Indians, although they are rather allied to them than to the nomadic Apaches, the warlike Navajoes, or the numerous tribes living on and near the Colorado. (See COCO-MARICOPAS, and PIMOS.)—The languages of the various Pueblo Indians are not sufficiently known and have not been compared with the care necessary to form an opinion as to the families to which they severally belong; it is safe, however, to say that several of them bear so close an affinity with each other as to render it certain that they are derived from the same stock. Living isolated as they do, and having but little communication with each other, their languages slowly change, and the lapse of a few generations without any intercourse would make them appear as different tribes. If among civilized nations changes are produced from such causes, how much greater must they be among rude and uncultivated people who have no written language.—The civilization which belongs to the Pueblo Indians was not introduced among them by Europeans. They practised agriculture and the arts of spinning and weaving, as well as the manufacture of pottery, when first visited by the Spaniards in the middle of the 16th century. With their rude implements they dug irrigating canals and ditches. The earliest accounts of these semi-civilized Indians were given by Alvar Nunez, who, in his remarkable journey from Florida to the shores of the Pacific, between the years 1529 and 1536, visited them. He was followed in 1539 by the friar Marco de Niza, and in 1540 by Coronado, both of whom explored the country N. and S. of the river Gila, and visited many of the Indian towns. Fernando Alarcon in the same year succeeded in pushing his way up the gulf of California, and thence far up the Colorado river. These early explorers have left us full accounts of what they saw, which admit of no doubt that they visited the very tribes now known as the Pueblo Indians. De Niza describes Cevola as a "great city, inhabited with great store of people, and having many streets and market places. In some parts of this city," he continues, "are certain very great houses of five stories high, wherein the chief of the city assemble themselves at certain days of the year. The houses are of lime and stone. . . . . The people are somewhat white; they wear apparel, and lie in beds; their weapons are bows; they have emeralds and other jewels, although they esteem none so much as turquoises. . . . . Their apparel is of cotton and of ox hides, and this is their most commendable and honorable apparel." Coronado's journey was far more extensive than that of De Niza. He speaks of Cibola, which he visited, as containing "excellent good houses of three or four stories high, wherein are good lodgings and fair chambers, with ladders instead of stairs, and certain cellars under the ground very good and paved, which are made for winter; the ladders which they have for their houses are all in a manner movable and portable, which are taken away and set down when they please." This city of Cibola or Cevola was visited some 50 years later by Espejo, who states that it was also called Zuñi. This place is still in existence, and occupied by one of the most intelligent tribes of Pueblo Indians that remain. Coronado also speaks of several towns to the N. W., which were doubtless what are known as the 7 Moqui towns. Other towns, people, and localities are also mentioned which have been identified by recent explorers. Alarçon, in his voyage up the Colorado, found the Indians exceedingly numerous, having an abundance of maize, beans, and gourds. Their garments, their manners and customs, their large and high houses of stone, their agriculture, &c., all go to show that the civilization and arts which now attract so much attention existed 300 years ago, and had doubtless been known to their ancestors for generations before. The turquoises and emeralds mentioned by all the old Spanish travellers as being found among these Indians are supposed to have been a kind of bright blue and green stones, numbers of which are still found in the region of the Pueblos, and particularly when digging among the ruins of their early structures. It is probable that some of the settlements of the tribes visited by Coronado and other early explorers have been abandoned. Certain it is that many have changed their places of abode or become extinct, as numerous remains exist in various parts of New Mexico, some of which are far more extensive and exhibit a higher state of art than any of the existing habitations of this people. The whole valley of the Gila for 80 miles above the villages of the Pimo Indians bears traces that it was once occupied by a people who cultivated the soil by means of irrigating canals, who constructed large dwellings of adobe, and who made a superior kind of pottery. In this district is an edifice of adobe, originally 3 stories high, with very solid walls, which is still in good preservation. This building was abandoned and in a ruinous condition 3 centuries ago, when the Spaniards penetrated the country, while the plain for miles around is strewn with fragments of pottery and stone grinders similar to those used by the present tribes of Indians. Round heaps in all directions show that the population was probably large. In the valley of the Salinas, N. of the Gila, are similar remains, with evidences of an extensive artificial irrigation at a remote period. The same people seem to have extended themselves southward about 200 miles into the state of Chihuahua, as the numerous remains known as Casas Grandes, near a modern town and on a river of the same name, sufficiently prove. But except at this place, there are no remains of the Pueblo Indians south of the valley of the river Gila.

PUERTO BELLO, or Porto Bello, a seaport town of New Granada, situated on the N. side of the isthmus of Panama, 40 m. N. N. W. from Panama. It stands on the side and at the foot of a ridge of hills which almost surrounds the harbor, and consists of a principal street extending along the shore, which is crossed by several others. The population is inconsiderable, and consists chiefly of negroes and mulattoes with a few white families. The fine harbor of Puerto Bello was discovered by Columbus in 1502, and the town was founded in 1584; but though it for some time rivalled Panama, the unhealthy nature of the climate has caused it to be almost deserted. It was formerly strongly fortified. The British took Puerto Bello from the Spaniards in 1739.

PUERTO CABALLOS, a fine natural harbor on the N. coast of Honduras, in lat. 15° 49′ N., long. 87° 57′ W., and the northern or Atlantic terminus of the proposed Honduras interoceanic railway. The harbor is 9 m. in circumference, with a depth of from 4 to 12 fathoms. Connected with it is a large salt water lagoon, called Alvarado lagoon, 2 m. long by 1 m. broad, and with an average depth of 3 fathoms. Puerto Caballos was selected by Cortes as the principal port for New Spain, and he founded a town there called Natividad. For nearly 3 centuries it was the principal establishment on the coast, but was finally abandoned during the irruption of the buccaneers for the more defensible position of Omoa, 6 m. W. The Carib towns of Tulian and Cieniguita are situated on the S. shore of the harbor.

PUERTO DE LA MAR. See Cobija.

PUERTO PRINCIPE, Santa Maria de, an inland city of Cuba, capital of the department of the same name, situated between two small rivers near the centre of the island, 325 m. S. by E. from Havana, and 45 m. W. S. W. from Las Nuevitas, its port, with which it is connected by railroad; pop. 26,648. It is a place of considerable trade, the exports being chiefly sugar and tobacco, and the imports different kinds of manufactured goods. It was formerly the seat of the supreme court for all the Spanish colonies in America.

PUFENDORF, Samuel, a German publicist, born near Chemnitz, Saxony, Jan. 8, 1632, died in Berlin, Oct. 26, 1694. He was the son of a Lutheran clergyman, and was educated for the ministry at Grimma and the university of Leipsic. In 1656 he repaired to Jena, and under the influence of Erhard Weigel, whose system of teaching mathematics and philosophy was then attracting attention in Germany, he devoted himself to those studies, and also to that of the law of nature. Upon quitting Jena he was advised by his brother Isaac, who was in the employment of Oxenstiern, the prime minister of Sweden, to enter the foreign diplomatic service, and as the first step toward this object he became tutor to the son of the Swedish ambassador at Copenhagen. Being detained with the ambassador's family in Copenhagen in consequence of a war between Denmark and Sweden, he employed his leisure in preparing a work on general law, in which the principles of Grotius, Hobbes, and other jurists were combined with observations of his own. This was published in Holland in 1660 under the title of *Elementa Jurisprudentiæ Universalis*, and, notwithstanding its harsh and repulsive style, attracted great attention from the original views which it embodied. It was dedicated to the elector palatine, Charles Louis, who, in consideration of the merit of the work as well as of the compliment paid him, founded at the university of Heidelberg a professorship of the law of nature and of nations, and placed Pufendorf in the chair, and also intrusted him with the education of his son. His lectures were attended by numbers from all parts of Germany, and the university, previously in a languishing condition, recovered during his residence much of its ancient prestige. The constitution of the Germanic empire formed the next subject of his investigations, and in his *Severini a Monzambano, De Statu Imperii Germanici*, published at Geneva in 1667, he showed that the Germanic system was an incongruous assemblage of discordant parts, and the parent of many social and political abuses. At the same time he pointed out practical remedies for the evils enumerated. The work was translated into the chief languages of Europe, but excited much hostile criticism in Germany, particularly in Austria, where it was placed upon the *Index Expurgatorius* and ordered to be burned by the hangman. Pufendorf defended the work, without acknowledging the authorship, but found his position so uncomfortable, in consequence of the acrimonious controversy in which he became involved with German publicists, that in 1670 he gladly accepted from Charles XI. of Sweden the professorship of the law of nations at the university of Lund. Two years later he published there the work on which his reputation now rests, the treatise in 8 books *De Jure Naturæ et Gentium* ("On the Law of Nature and Nations"), of which he subsequently prepared an abridgment with some variations, entitled *De Officio Hominis et Civis Libri duo* ("On the Duties of a Man and a Citizen"). It presents a careful digest of the law of nature, and in its statement of principles corresponds closely with the work of Grotius *De Jure Belli et Pacis*. In arrangement, however, the two treatises differ essentially, Pufendorf considering first the law of nature, and afterward that of nations, while Grotius inverts this natural order of treating the subject. Recent writers, as Wheaton and Mackintosh, rate very low Pufendorf's original contributions to the science of international law, praising chiefly his industry and research; but his reputation was greatly enhanced by this treatise, and on the invitation of the king of Sweden he removed to Stockholm, and was appointed councillor of state and royal historiographer. In the latter capacity he published his *Commentarii de Rebus Suecicis ab Expeditione Gustavi Adolphi usque ad Abdicationem Christinæ* (Utrecht, 1686), a work of no great value, notwithstanding the copious materials placed at his disposal. In 1688 he accepted a similar office at the court of Frederick William, elector of Brandenburg, the history of whose reign he published under the title of *Commentarii de Rebus Gestis Frederici Wilhelmi Magni, Electoris Brandenburgici*, which is even less creditable to him than the last mentioned work. Of his great treatise, first printed in German at Leyden in 1672, and afterward at Frankfort much augmented in 1684, the best edition is that published at Leipsic *cum Notis Variorum a Gottl. Mascovio* (2 vols. 4to., 1744). The French translation by J. Barbeyrac (2 vols. 4to., Amsterdam, 1712), with original notes, is the version most esteemed. There is an English version by Basil Kennet, with Barbeyrac's preface and notes translated by Carew (London, 1749). Pufendorf also wrote a number of other works of a public or controversial character, most of which are forgotten.

PUFF BIRD, an appropriate name for the *bucconinæ*, an American sub-family of diurnal fissirostral birds, placed by Gray in the kingfisher family, but by the older and some modern writers in the scansorial family of barbets or *capitoninæ*; the generic name *bucco* is applied by Cuvier to the latter.—In the typical genus *bucco* (Linn.), as recognized by Gray, the bill is long, strong, elevated, and very broad at the base, where it is furnished with tufts of strong bristles, and suddenly curved at the tip, which is hooked; the gape very wide; nostrils concealed by the projecting plumes and bristles; wings moderate and rounded, the 1st quill short and the 4th the longest; tail long, broad, even, rounded on the sides; tarsi shorter than the middle toe, strong, and covered in front with transverse scales; toes 2 before and 2 behind, the outer anterior the longest, and the claws long and acute. There are about a dozen species described, in tropical South America; the name is derived from their habit of puffing out the plumage of the head, which gives them a heavy and ill-balanced appearance. They are solitary, silent, and melancholy-looking birds, living generally in retired woods, perching on some low and thickly leaved branch, with the large head drawn between the shoulders; thus they remain for hours at a time, occasionally darting after beetles and other insects, returning to the same perch, which they are said to frequent for months together; they sometimes climb like woodpeckers, supported by the tail, in search of insects in the bark; the nest is made in the hollows of trees; they are not shy, and sometimes select spots near human habitations; their colors are sombre, very different from those of the barbets with which some authors have classed them. The collared puff bird (*B. collaris*, Lath.) is 7½ inches long; rufous above, striated with black; whitish on the chest, terminated by a broad black band; a similar band across the shoulders; abdomen rufous white; bill 1¼ inches and horn-colored. The pied puff bird (*B. macrorhynchus*, Gmel.)

is black, with a black and larger bill; general color black, with forehead, throat, abdomen, and tip of tail white. The spotted puff bird (*B. tamatias*, Gmel.) is reddish brown, lighter below spotted with black; forehead and throat light rufous; black stripe from bill to nape, and white nuchal band. These species are from Cayenne and other parts of Guiana.—In the genus *monasa* (Vieill.) the bill is shorter, strong and hooked, with the culmen more curved and the sides more compressed; 4th and 5th quills equal and longest; tail very long, broad, and rounded. There are about half a dozen species in tropical America, with habits similar to the last. The wax-billed puff bird (*M. atra*, Bodd) is 11½ inches long; bill 1½, orange yellow; head, neck, and upper parts greenish black; some white on the wing coverts; breast and belly cinereous; a short horny spine at bend of wing. The white-bearded puff bird (*M. leucops*, Licht.) is general blackish lead color, with the bill red and its base surrounded by a band of whitish feathers. The striped puff bird (*M. fusca*, Gmel.) is about 7 inches long, of a dark brown color, striped on the head, sides of neck, and back with light rufous; below rufous white; upper breast white, bounded by a narrow semicircle of black. These species are from Cayenne.—In the genus *chelidoptera* (Gould) the bill is shorter than the head, with base broad and elevated, culmen curved as in the cuckoos, and tip sharp; wings reaching nearly to end of tail, 3d and 4th quills equal and longest; tail very short and even, and tarsi very short. Gray describes a single species, the swallow puff bird (*C. tenebrosa*, Gould), about 7 inches long, of a blackish color, with a black bill; rump white, and lower part of abdomen light rufous. It is a bird of powerful flight, resorting to the topmost branches of trees, whence it darts in pursuit of insects.—Figures of many of these puff birds may be found in Swainson's "Birds of Brazil and Mexico" (London, 1841).

PUFFIN, a web-footed bird. See AUK.

PUGATCHEFF, YEMELYAN, a Cossack chieftain and pretender to the throne of Russia, born in Simoveisk on the Don in 1726, executed in Moscow, June 10, 1775. He first appears as the leader of a band of disciplined robbers. In the 7 years' war he served first in the Prussian and then in the Austrian army, and subsequently in the Russian war against Turkey. Returning to his native land, he was imprisoned for seditious conduct; but having recovered his liberty, he went to Yaitzkoi, where a resemblance noticed between himself and Peter III. prompted him to pass himself off as the murdered monarch, to forge a tale about his escape from death, and to declare that he was now to set about the task of regaining his throne. The insurrection broke out in the middle of 1773, when a manifesto of Pugatcheff in the name of Peter III. was published. At first he had only a few hundred men, but after he had got possession of the fortress of Yaitzkoi, and the religious sect of the Raskolniks had embraced his cause, the peasantry went over to his [illegible] in large numbers. With these he took numerous fortresses on the Ural, the Volga, and [illegible] Don, when his army increased to a most alarming extent, numerous Tartar and Finnish [illegible] also taking up arms for him. He now marched upon Moscow, but his courage failed [illegible] critical moment, and he was betrayed and [illegible] by his comrades for 100,000 rubles to M[illegible]son and Suwaroff. The lives of 100,000 [illegible] were lost in this insurrection.

PUGET, PIERRE, a French sculptor, pa[illegible] architect, and ship builder, born in Mars[illegible] Oct. 31, 1622, died Dec. 2, 1694. He was [illegible]prenticed to a ship builder and wood ca[illegible] travelled on foot to Italy, and after s[illegible] great hardships obtained admission to th[illegible]dio of Pietro di Cortona, a painter in R[illegible] Returning to Marseilles in 1643, he soon f[illegible] employment, and was commissioned by [illegible] duke de Brézé to design a magnificent [illegible] which, in honor of the queen, Anne of A[illegible] was called La Reine. This splendid spe[illegible] of naval architecture, decorated with car[illegible] by Puget, was completed after 3 years of [illegible]mitting labor. Puget now returned to [illegible] and during a stay of nearly 7 years his [illegible] for architecture became paramount. In [illegible] he was at home again, and painted many ch[illegible] pictures for Marseilles, Aix, Toulon, Cuers [illegible] La Ciotat. A serious illness obliging h[illegible] give up painting in 1655, he devoted hims[illegible] sculpture in marble. The gate and the bal[illegible] of the city hall at Toulon, which he bu[illegible] carved, were his first works. Fouquet com[illegible]sioned him to obtain in Italy a supply of Ca[illegible] marble for the embellishments of his pri[illegible] country seat at Vaux, but he had proceede[illegible] further than Genoa when he heard of the fa[illegible] his employer. He was then induced to se[illegible] Genoa, where he executed the statues of A[illegible]sandro Sauli and St. Sebastian in the churc[illegible] Carignano, that of St. Philip Neri, a group [illegible] the Assumption for the hospital, a Madonna [illegible] the Balbi palace and another for the Carr[illegible] palace, the gilt bronze tabernacle and ange[illegible] the church of St. Cyr, the altar of Nostra D[illegible]na delle Vigne, and the group of the "E[illegible]ment of Helen." He made also a magnifi[illegible] bass-relief representing the Assumption for [illegible] duke of Mantua. He was in the tide of pro[illegible]perity at Genoa, when in 1665, on the reco[illegible]mendation of Cavaliere Bernini, who on a vi[illegible] to France had greatly admired his works, [illegible] was recalled by Colbert, and appointed direct[illegible] of ship decorations at the dockyards of Toulon. On his arrival there he commenced building a large ship, Le Magnifique, adorned with carvings on a scale of unheard of grandeur; this ship was soon afterward lost at sea. He began an arsenal at Toulon; but its progress being hindered by official intrigues, he retired in disgust to his native city. While attending to his duties as naval director, he had obtained 3 blocks of Carrara marble, and out of one of them he had partly carved the group u[illegible] hich his fame mainly rests, his "Milo of rotona devoured by a Lion." Lenôtre, hav- g seen the work in its unfinished state, was o impressed with it that he bestowed unbound- d praise upon it in the presence of Colbert and ouis XIV.; in consequence of which Puget ceived orders to complete the group for the ardens at Versailles. It was finished in 1683. is group of Andromeda and Perseus was completed in 1685, and brought to Versailles by his on; 3 years later he himself went there with is bass-relief of Alexander and Diogenes. On is return to Marseilles, which he had already dorned with many edifices and monuments, e superintended the building of the church of he charity hospital, executed his last work in ass-relief, "The Plague of Milan," and spent is later years in comparative retirement. For imself and family he had built a house in a tyle suited to his own genius, the gate of hich was surmounted by a bust of Christ with he motto: *Nul bien sans peine.* In 1807 a olumn surmounted by a bust was erected in his onor by the city of Marseilles.

PUGET SOUND, a collection of inlets, sit- ated on the N. W. coast of Washington terri- ory, forming the S. termination of Admiralty nlet, which is connected with the Pacific by the trait of Juan de Fuca. The sound covers an rea of about 15 sq. m., and the narrows which onnect it with the inlet are about 4½ m. long nd 1 m. broad; all the approaches are completely commanded by Point Defiance on the E. he inlets, in the order in which they succeed rom the entrance, have been named, after the fficers of the U. S. exploring expedition, Carr's, ase's, Hammersley's, Totten's, Eld's, Budd's, nd Henderson's, and are united by passages hich form several islands and peninsulas. hey are all safe, deep, and capacious harbors, urrounded by fertile land and well supplied ith water. On many of the islands and pen- nsulas good slate and sandstone are found; nd the shores are covered with abundance of xcellent timber. A considerable extent of round is cultivated at the S. part of the sound, nd several saw mills have been erected on e shores. Timber, grain, butter, and cheese re exported to different parts of the W. coast f North and South America and to Australia. he sound was named after an officer in Van- ouver's expedition.

PUGHE, WILLIAM OWEN, a Welsh author, orn at Tyn y Bryn, Merionethshire, in 1759, ied in 1835. His original name was William Owen, to which he added that of Pughe late n life, upon receiving an inheritance. At the ge of 17 he was sent to London to earn his iving, and there made the acquaintance of Owen Jones, a tradesman and an enthusiast r ancient Welsh literature, with whose upport and encouragement he entered upon a ourse of study for the elucidation of that sub- ect. The two published in conjunction in 789 the poems of Dafydd ap Gwilym, a bard f the 14th century. This was followed by the works of other poets and by translations; and in 1801, a third Welshman, Edward Williams, being associated with them, they published the first two volumes of the "Myvyrian Archaiology;" a third volume appeared in 1807. Pughe also prepared a Welsh and English dictionary (1793–1803), and the "Cambrian Biography" (1803); published a Welsh magazine entitled *Y Greal*; translated into Welsh the "Paradise Lost" and Heber's "Palestine;" and edited "Ancient Laws and Institutes of Wales," printed by the record commission in 1841.

PUGIN. I. AUGUSTUS, an English architectural draughtsman of French extraction, born in the latter part of the 18th century, died Dec. 19, 1832. He was frequently employed in the early part of his career in making architectural drawings for engraving, but is best known by a series of elaborate works on the Gothic architecture of the middle ages. These comprise "Specimens of Gothic Architecture selected from various ancient Edifices in England," &c. (2 vols. fol. and 4to., with 114 plates, 1823), the descriptions of which were written chiefly by E. J. Wilson; "Architectural Illustrations of the Buildings of London" (2 vols. 4to., 1824), and "Specimens of the Architectural Antiquities of Normandy," &c. (1825–'8), both published in conjunction with John Britton the antiquary. He also made the drawings for a work entitled "Paris and its Environs displayed," and prepared, with the assistance of his son, "Gothic Ornaments selected from various Buildings in England and France." II. AUGUSTUS WELBY NORTHMORE, son of the preceding, born in England in 1811, died at Ramsgate, Sept. 14, 1852. From his father he acquired a taste for mediæval architecture, and first turned his attention to designing ornamental Gothic furniture and metal work. On these subjects he published "Designs for Gothic Furniture in the Style of the 15th Century" (1835), "Designs for Iron and Brass Work in the Style of the 15th and 16th Centuries" (1835), "Designs for Gold and Silver-Smiths' Work" (1836), and "Ancient Timber Houses" (1836), all of which had a material influence in promoting the late revival in the taste for Gothic forms. He also published "Contrasts, or a Parallel between the Noble Edifices of the 14th and 15th Centuries, and similar Buildings of the present Decay of Taste" (2d ed., 1841), a work which excited the animadversion of architects, chiefly on account of the caustic tone in which the author conveyed his ideas. Becoming a convert to the Roman Catholic faith, he devoted himself with singular earnestness to the study of ecclesiastical Gothic architecture, and thenceforth his talents were almost exclusively employed in the erection or embellishment of edifices connected with the public worship or discipline of the Catholic church, the number of which is said to exceed that undertaken by any other Englishman since the reformation. Among his early patrons was the earl of Shrewsbury, for whose seat of Alton Towers he designed a church, school house, and monastery. Such was his devotion to his faith that he invariably declined to design for Protestant places of worship, and seldom accepted commissions from Protestants for buildings for secular purposes. The chief exceptions to this rule were the gateway to Magdalen college, Oxford, and the elaborate mediæval ornamentation of the new parliament houses at Westminster. Having amassed a considerable property, he purchased an estate at Ramsgate, and erected thereon a house, church, schools, &c., all of which were dedicated to St. Augustine. Toward the close of his life his religious zeal perceptibly increased, and in 1850 he published a number of pamphlets testifying his devotion to his faith, among which were "An Address to the Inhabitants of Ramsgate," "An Earnest Appeal for the Revival of the ancient Plain Song," "The Present State of Public Worship among the Roman Catholics," &c. In the succeeding year his intellect yielded to the severe mental excitement in which he indulged, and for several months he was the inmate of a lunatic asylum. He recovered sufficiently to be removed to his own residence, but died soon after. In principle he was so thoroughly wedded to Gothic architecture, that he was unwilling, as he expressed it, "to deviate one tittle from its spirit." His works have had a powerful influence on contemporary and subsequent architects. His chief publications, in addition to those mentioned, are: "Examples of Gothic Architecture" (3 vols. 4to., 225 plates, 1838); "True Principles of Pointed or Christian Architecture" (1841); "An Apology for the Revival of Christian Architecture" (1843); and "Glossary of Ecclesiastical Ornament" (1844).

PULASKI, the name of counties in 7 of the United States. I. A S. W. co. of Va., bordered E. partly by New river, which, turning to the W., intersects it toward the S., Little river, a branch of New, completing the E. boundary; area, about 300 sq. m.; pop. in 1860, 5,416, of whom 1,589 were slaves. It lies between two mountain ranges, Walker mountain on the N. W. and the Blue ridge on the S. E. The surface is broken and the soil generally fertile. The productions in 1850 were 179,510 bushels of Indian corn, 35,284 of wheat, 63,367 of oats, 2,639 tons of hay, and 20,502 lbs. of wool. There were 5 grist mills, 5 saw mills, 5 tanneries, 9 churches, and 292 pupils attending public schools. Value of real estate in 1856, $1,707,526, being an increase since 1850 of 84 per cent. It is intersected by the Virginia and Tennessee railroad, which passes through the capital, Newbern. II. A central co. of Ga., intersected by the Ocmulgee and Little Ocmulgee rivers, and drained by their branches; area, about 650 sq. m.; pop. in 1860, 8,744, of whom 4,106 were slaves. It has a level surface toward the S. and rolling toward the N. The productions in 1850 were 229,815 bushels of Indian corn, 60,976 of sweet potato 5,501 bales of cotton. There were 2 saw 13 churches, and 127 pupils attending schools. Capital, Hawkinsville. III. A tral co. of Ark., intersected by the Ark river and drained by its branches; area sq. m.; pop. in 1860, 11,700, of whom were slaves. In the S. the surface is lev in the N. and W. hilly, and the soil is ately fertile. Lead, slate, and excellent are found. The productions in 1854 were 198 bushels of Indian corn, 26,960 of oa 2,038 bales of cotton. In 1850 there w grist mills, 3 saw mills, 6 churches, and pupils attending public schools. Capital tle Rock. IV. A S. co. of Ky., bordered the Cumberland river, and E. by the Castle; area, about 550 sq. m.; pop. in 17,203, of whom 1,330 were slaves. It diversified surface, with several elevated and contains iron, lead, and coal. The ductions in 1850 were 558,864 bushels dian corn, 13,385 of wheat, 125,002 of 6,883 lbs. of tobacco, and 34,876 of There were 35 churches, and 1,220 pupi tending public schools. Capital, Som V. A N. W. co. of Ind., intersected by T canoe river; area, 432 sq. m.; pop. in 5,703. It has a nearly level surface, equally divided between prairie and oak ings, and a generally fertile soil. The pr tions in 1850 were 27,593 bushels of w 95,915 of Indian corn, 15,050 of oats, 2,2 of hay, and 3,889 lbs. of wool. Capital, W mac. VI. A S. co. of Ill., separated from by the Ohio river, and bordered N. W. by C river; area, about 175 sq. m.; pop. in 3,950. It has a level and well wooded su and a fertile soil. The productions in 185 87,145 bushels of Indian corn, 16,326 of 1,474 lbs. of wool, and 25,695 of butter. Th were 5 saw mills, 2 tanneries, 2 churches 149 pupils attending public schools. It is tersected by the Illinois central railroad. C ital, Caledonia. VII. A S. co. of Mo., sected by the Gasconade river, and drained several of its branches; area, 1,332 sq. pop. in 1860, 3,834, of whom 56 were sla The surface is hilly and the soil generally tile. The productions in 1850 were 24 bushels of Indian corn, 11,352 of wheat, 838 of oats, 11,894 lbs. of wool, and 54,8 butter. There wero 2 grist mills, a tann and 75 pupils attending public schools. Cap tal, Waynesville.

PULASKI, Casimir (Pol. Kazimierz P lawski), count, a Polish patriot, who fo in the war of the American revolution, born 1747, died from a wound received in the at tack on Savannah, Oct. 11, 1779. He was son of a Polish nobleman, the starosta of W reck, who was the chief organizer of the cele brated confederation of Bar, which was also signed by his 3 sons (1768). Casimir while st young had been in the service of Duke Char of Courland, and now entered heartily into the ar for the liberation of his country from the ower of Russia. Forced to cross the Dniester, e took refuge after the storming of Bar in e monastery of Berditchev with 300 men, and fter sustaining a siege of several weeks capitulated on the condition that the garrison should e set at liberty. He himself, however, was ept prisoner, and was not freed until he had ledged himself to bear proposals for a reconiliation to the chiefs of the confederates; but s soon as he was set at liberty he refused to eep a promise extorted by violence and fraud. oining his father in Moldavia, he made incurions across the Dniester, and attacked the ussians and fortified posts within the Polish orders. He carried on a desultory war in various parts of the country, making up for the ant of discipline and numbers in his troops by e activity of his movements, until an unsuccessful attempt to gain possession of the person f the king Stanislas Augustus, in 1771, caused sentence of outlawry and death to be passed gainst him, on the ground that it was his intion to assassinate the monarch. The coalion of Austria, Russia, and Prussia for the conuest and division of Poland, under the pretence f protecting the government, was soon after ompleted, and resistance became hopeless. ulaski, who had lost his father and brothers the war, made his way to Turkey after a ries of adventures and perils; but, unable secure any important aid from that couny, he went to France. There he determined to join the Americans, then fighting for dependence, and, with high recommendaons from Franklin to Washington, arrived Philadelphia in the summer of 1777. He first served in the army as a volunteer; but days after the battle of the Brandywine, in hich he distinguished himself, he was apointed by congress commander of the cavalry ith the rank of brigadier-general. After 5 onths at the head of this body he resigned s command, and entered the main army at alley Forge in March, 1778. There he proosed to organize an independent *corps*, consting of cavalry, lancers, and light infantry, d this proposal was accepted by congress, ho empowered him to raise and equip such a dy of men to the number of 268, and, if the periment were successful, to a still larger umber. By October 330 men were in this rps, which was called Pulaski's legion. With is he marched, in the beginning of Feb. 1779, South Carolina to put himself under the ders of Gen. Lincoln, then commanding the partment of the South. He reached Charlesn May 8, and while there vigorously opposed e project entertained by the governor and uncil of surrendering the place to the British my then before the city. In September the ench under Count d'Estaing and the Americans prepared to besiege Savannah, and during e march to Georgia Pulaski's legion did efctual service in reconnoitring. When near vannah he heard of the landing of the French general, and received from him a complimentary letter, in which he said that, "knowing Count Pulaski was there, he was sure he would be the first to join him." The two armies united on Sept. 16, and on Oct. 9 it was determined to carry the town by assault. Pulaski was placed at the head of the French and American cavalry, and during the engagement received a mortal wound. He was taken on board the U. S. brig Wasp, which lay in the Savannah river, died after lingering two days, and was buried in the river. A monument to his memory voted by congress has never been erected, but one was raised by the citizens of Georgia in Savannah, of which Lafayette during his triumphal progress through the United States laid the corner stone.

PULCI, LUIGI, an Italian poet, born in Florence in 1431, died there in 1487. He obtained through the patronage of the Medici family an inferior office under the republic, and was one of that brilliant company for whom Lorenzo de' Medici kept a place at his table. Urged by the mother of his patron to employ his genius in some nobler work than the casual effusions that he put forth from time to time, he began the composition of his *Morgante Maggiore*, a poem which, while it classes him as the last of the old romancers, also entitles him to rank as the first in point of time of the Italian epic poets. The subject is that legend of Charlemagne and his paladins which refers to the treason of Gan, Gano, or Ganellone, a personage very bitterly denounced wherever his name is mentioned in the ancient romances for his complicity with the Saracens in bringing about "the fatal day of Roncesvalles." Morgante is represented by Pulci as a giant, and is the principal actor in the poem, though the real hero is Orlando. The dignity of the epic is preserved wherever Orlando appears; the incidents that relate to him are natural and impressive; but in all other parts the poet gives way to what is grotesque in the old legends, and relates the absurd and extravagant fables in colloquial manner and with an air of banter and burlesque exquisitely humorous. It was first published in Florence in 1481. One canto of it was translated into English by Lord Byron, and the poem was his acknowledged model with respect to style in "Beppo" and "Don Juan." Pulci was also the author of a number of sonnets and other short pieces.

PULKOWA. See OBSERVATORY.

PULLEY. See MECHANICS, vol. xi. p. 326.

PULQUE, a favorite drink of the inhabitants of Mexico and of Central and South America, prepared from several varieties of the *agave Americana*, from the fibres of whose leaves the Mexicans also make their paper. The plant is called *metl* by the Mexicans and *maguey de Cocuiza* in Caracas. Just before it blossoms the sap is collected in pitchers by cutting the buds, and is allowed to ferment slightly. In this state it is relished by foreigners, but the natives prefer it when it has passed into its second fermentation, at which time it has an acid taste and a smell like that of putrid meat. When allowed to ferment still further it turns into vinegar, and if boiled down becomes sirup. Pulque brandy is made of it, and when water and sugar are mixed with the sap and the whole allowed to ferment a few hours, the drink is called *tepache*.

PULSE, the throbbing of the arteries caused by the intermitting impulses communicated to the blood by the heart's contractions, propagated as a wave by the elasticity of the arteries, perceptible to the touch in all but the smallest vessels, and visible when they are superficial or exposed, the pulsation being nearly synchronous with the contraction of the left ventricle. At each pulsation the capacity of the artery is augmented by an increase of diameter and by a partial elongation, the vessel being thereby lifted from its bed; this increase has been estimated for the carotid artery as $\frac{1}{23}$ part, but this can be only an approximation. The wave of the contained blood may be propagated with a different velocity from the wave along the walls of the artery, explaining many cases of double pulse, especially after the subsidence of vascular excitement. The variation from synchronism between the ventricular contraction and the pulse in a state of health is from $\frac{1}{7}$ to $\frac{1}{6}$ of a second, depending on the distance of the part examined from the heart; this interval may be increased in atonic conditions of the arterial system. The pulse is liable to vary, within the limits of health, from the several diversities of age, sex, stature, muscular exertion, condition of the mind, state of the digestive process, and period of the day. The following table is given by Carpenter as an approximation to the average frequency of the pulse per minute at different ages:

In the fœtus	140 to 150
Newly born infant	130 to 140
During the 1st y'r.	115 to 130
" " 2d "	100 to 115
" " 3d "	95 to 105
" " 7th to 14th year	80 to 90
During the 14th to 21st year	75 to 85
During the 21st to 60th year	70 to 75
In old age	75 to 80

According to Dr. Guy, the pulse of the adult female usually exceeds that of the adult male of the same age by 10 to 14 beats a minute; according to Volkmann, the pulse is less frequent as the stature is greater, about 4 beats for a half foot in height. It is well known that muscular exertion increases the frequency of the pulse. The effect of posture has thus been expressed by Dr. Guy:

Average beats per minute in	Standing.	Sitting.	Lying.
Healthy males	81	71	66
Healthy females	91	84	79

According to this the difference between standing and lying in the former is $\frac{1}{5}$ of the whole, in the latter $\frac{1}{8}$; when this change is effected by muscular effort the variation is greater, accounting for many cases of sudden death in persons with disease of the heart or in very weak conditions on quickly assuming an erect position. Mental excitement, the digestive process, alcoholic drinks, and elevation above the sea, accelerate the pulse; as a general rule, though with numerous exceptions, it is more frequent in the morning than in the evening, and in sanguine than in lymphatic temperaments. The pulse is slower during sleep, and from the effect of rest, diet, cold, venesection, and the action of many drugs, especially digitalis, aconite, and hellebore. The pulse may be counted in any artery, and in a manner familiar to all, but most conveniently in the radial at the wrist, in the carotids, temporals, brachial, or femoral. The average numerical proportion of the arterial pulsations to the respiratory movements varies from 4 or 5 to 1; when this proportion is widely departed from, there is either some general diseased condition accompanied with fever, some obstruction to the proper aëration of the blood, or some disorder in the nervous system; in inflammatory or acute diseases, fevers, &c., the pulse may be raised to 120 and 160 in the adult, and so that it cannot be counted in the child; in pneumonia, with the quickened pulse the number of respirations increases more rapidly, the above proportion becoming as 3 or even 2 to 1; in hysteria similar increase may occur in both without any serious cause. The pulse is continued even into the capillaries; the respiratory pulse, long ago described by Haller, is the partial emptying of the veins near the heart by inspiration and their partial filling during expiration, which may be seen in the neck of thin persons or those suffering from pulmonary diseases; in the latter diseases, when there is obstruction to the exit of the blood through the pulmonary artery, the tricuspid valve does not close completely, and regurgitation takes place into the superior vena cava, causing a pulsation in the jugular veins synchronous with that in the carotids from the left ventricle; there is also a venous pulse in varicose aneurism, where the artery and vein communicate. Galen first drew attention to the pulse as a diagnostic sign, and enumerated more than 30 different conditions of it, for which see Chomel's *Pathologie* ([illegible] Paris, 1824); when it is above 90 it is called febrile; it is also irregular or intermittent in diseases of the heart, great vessels, and pericardium, and some spasmodic affections. In fishes the heart beats 20 to 30 times in a minute, and in some of the lower forms pulsations occur in accessory lateral hearts or swellings, both venous and arterial; the pulsations are much slower than this in reptiles, and in the actively breathing birds are more than 100 in the natural state.

PULSZKY, Ferencz Aurel, a Hungarian patriot and author, of Polish descent, born at Eperies, Sept. 17, 1814. He studied in his native town and at Miskolcz, in 1833 passed the examination as an advocate, in 1836 travelled through Germany, Italy, England, Scotland, and Ireland, and in the same year became a member of the archæological institute of [illegible] and in 1837 a member of the Hungarian academy. Chosen to represent his native county of Sáros in the diet of 1839-'40, he joined the op- position or liberal party, and was named secre- ary of a commission to frame a code for Hun- ary. He was not reëlected to the diet, but rdently advocated the liberal cause in the olumns of the Augsburg *Allgemeine Zeitung*, and was a prominent supporter of the Hunga- ian union (*védegylet*) for the protection of ome manufactures. Upon the revolution of March, 1848, he became, under Prince Ester- azy at Vienna, under secretary of state for Hungary. His influence upon Hungarian af- airs and his activity in this position were very reat; and early in Oct. 1848, when an open onflict between Austria and Hungary was im- minent, Pulszky received an autograph letter rom the emperor, which informed him that is "resignation was accepted," though no esignation had been tendered. A few days ater, however, a revolutionary outbreak drove he emperor from his capital. When Windisch- rätz became master of Vienna, Pulszky escaped o Pesth, and was subsequently sent to London y Kossuth, to endeavor to obtain from Eng- nd some support for the Hungarian cause. e remained in England until joined there by ossuth, whom he accompanied on his visit the United States. In March, 1861, having emoved from London to Turin, he was elected member of the diet of Pesth by the district Szécsén in the county of Nógrád, but was revented from reëntering his native country y the Austrian government. Pulszky has pub- ished *Aus dem Tagebuche eines in Grossbri- annien reisenden Ungarn* (Pesth, 1837); *Die akobiner in Ungarn* (2 vols., Leipsic, 1851); Tales and Traditions of Hungary" (London, 851); "Red, White, and Black," an account travels in the United States (London, 1852); *deen zur Philosophie der Geschichte Ungarns*, nd several other books of a miscellaneous char- cter.—Theresa Walther, wife of the preced- g, born in Vienna in 1815, accompanied her usband (to whom she was married in 1845) England, and subsequently on his visit to e United States, and, in addition to her joint thorship of the "Tales and Traditions" and Red, White, and Black," has written "Me- oirs of a Hungarian Lady" (2 vols., London, 850).

PULTENEY, William, earl of Bath, an Eng- h statesman, born in 1684, died in 1764. e was educated at Westminster school and at hristchurch, Oxford, travelled on the conti- ent, and became member of parliament for e borough of Hedon in Yorkshire. This po- tion he owed to his guardian, Henry Guy, ho subsequently left him a legacy of £40,000 d landed estate to the amount of £500 a ar. Having joined the whig party, he con- nued to represent Hedon throughout the hole reign of Queen Anne, and conducted mself with so much warmth in the prosecu- n of Sacheverell, that when in 1710 the tories obtained control of the government, they removed his uncle John Pulteney from the board of trade. He defended Walpole in the prosecution instituted against him in 1712; and when that minister resigned in 1717, Pulteney also gave up his office of secretary at war, to which he had been appointed on the accession of George I. But not long after a coolness sprang up between the two friends; and although, when Walpole resumed office in 1720, Pulteney was appointed cofferer of the household, the latter went over to the opposition in 1725, and after his dismissal became one of the most bitter enemies of the minister. He allied himself with Bolingbroke, and published pamphlets in which he attacked the ministry so virulently as to bring about a duel in 1731 between himself and Lord Hervey. Through the brilliancy of his speeches, and the patriotic sentiments with which they were filled, he became the most popular man in the nation, and in 1742 succeeded in driving Walpole from power. When in opposition he seems to have made the declaration that he would never take office; and now, when all England was at his feet, he constructed a cabinet, leaving himself out, though accepting a peerage. The people now considered themselves as betrayed, and by the new ministry he was treated with indifference and abuse. As Chesterfield wrote: "He shrunk into insignificance and an earldom." When in 1746 the Pelham ministry resigned, Pulteney became premier; but so little influence had he, that he was unable to obtain the assistance of any men of importance, and in consequence he held office for only two days. After this he was comparatively little in public life, but in 1760 he published "A Letter to Two Great Men" (Pitt and the duke of Newcastle), which seems to have attracted attention for a time. As his only son had died before him, the peerage in his family became extinct.

PULTOCK, Robert, an English author, whose only known work, published in London in 1750, is a romance, entitled "The Life and Adventures of Peter Wilkins," which describes an imaginary race of flying islanders in the South Pacific. It has gone through many editions both in England and the United States, and has become a standard work of fiction. The name of the author was unknown till 1835, when, at a sale by auction of books and manuscripts which had belonged to Dodsley the publisher, the original agreement for the copyright of the book was found, in which Pultock is described as "of Clement's Inn, gentleman," from which it is supposed that he was a bencher of the Inn. From the agreement it appears that he had sold his story for £20, with 12 copies of the work, and a set of the first impressions of the engravings that were to accompany it. Nothing more is known of him. "His book," says Southey, "is a work of great genius, and I know that both Sir Walter Scott and Mr. Coleridge thought as highly of it as I do. His winged people are the most beautiful creatures of imagination that ever were devised."

PULTOWA, or **Poltava**, a government of European Russia, province of Ukraine, bounded N. by Tchernigov and Koorsk, E. by Kharkov, S. by Ekaterinoslav and Cherson, and W. by Kiev; area, 18,684 sq. m.; pop. in 1856, 1,753,144. The surface consists of an almost unbroken plain, which declines gradually to the S. W., where the Dnieper flows along the frontier for upward of 200 m., and receives the drainage of the government by several rivers, the most important of which are the Sula, Vorskla, and Orel. Potters' clay, lime, chalk, and saltpetre are the most valuable minerals. The soil is remarkably fertile, and only a small portion in the S. E. part is barren. The principal crops raised are barley, oats, wheat, buckwheat, and millet. Large numbers of cattle and sheep are reared. The manufactures consist of woollen goods, leather, and brandy. Only a small percentage of the inhabitants can read and write.—**Pultowa**, the capital, is situated near the junction of the rivers Poltavka and Vorskla, 445 m. S. S. W. from Moscow; pop. in 1851, 20,071. It is surrounded by a wall and defended by a citadel near the centre of the town. There are a cathedral, 11 churches, a convent, and a school for cadets. The streets are broad and well laid out, and there is a large square with a monument in the middle erected in memory of Peter the Great, who near the town won the great battle (July 8, 1709) in which the Swedes were totally routed and Charles XII. obliged to take refuge in Turkey. (See Charles XII.) A fine obelisk stands upon the field, and divine service is annually performed in commemoration of the victory.

PULU, or **Vegetable Silk**, the long silky fibres that cover the stipes or stalks of a species of fern which grows in the Sandwich islands. A similar product has been known in Sumatra, obtained from a fern called the *penghawar* or *penawar djambi*. The long, sparkling, brown, hairy-like fibres which clothe the stems, resemble more the covering of animals than of plants; and it is supposed that from this plant originated the ancient fable of the Scythian or vegetable lamb. This was said to be an animal that sprung from a seed out of the earth, to which it continued rooted. It had a sort of flesh and blood, and lived by browsing all within its reach, till finally it died for want of further sustenance. The Russian name of the animal is *barometz*, which has been applied as a specific name to the plant. The Sandwich island pulu is the produce of a fern of the genus *cibotium*, the specific name of which is uncertain; or it may be produced by several species of this genus. It grows on lands elevated from 1,000 to 4,000 feet above the sea, and frequently reaches the height of 15 feet. Each plant, when 4 years old, produces 2 or 3 ounces of the fibres. These are gathered by women and children, and spread on rocks or mats to dry; the article is sold to the larger dealers, and packed i for exportation. The trade is princip fined to the districts of Hilo, Hamak Puna on Hawaii; and the shipment San Francisco, Australia, Vancouver's i &c. From the custom house returns waii, the trade is seen to have increased 2,479 lbs. in 1851 to 318,220 lbs. in 18 the introduction of the article into San cisco in 1854, it sold for 28 cts. per l now regarded as a staple export of the wich islands. By the natives it has l used for pillows, &c. When woven i duces a fabric intermediate in chara tween silk and wool. The East Indian has been introduced into the Dutch p copœia, and is employed, like cotton, tow, or beaver nap, as a styptic.

PUMA. See Cougar.

PUMICE, a porous feldspathic scoria volcanoes. The pores are linear, and as often to be barely visible except by th of a magnifying glass. Its specific gr 2.2 to 2.4, but by reason of its spongy pieces of it are often buoyant enough on water. It consists chiefly of silica sometimes 17 per cent. of alumina, 6 per of soda, and 4 of potash. It is of shades of color, passing into yellow and The chief source from which it is obtained commercial purposes is Campo Bianco, the Lipari islands, where it forms a nearly 1,000 feet high. In the arts pum largely employed, mostly in a pulverized as a polishing material. It is also used i for grinding and smoothing surfaces of plates, leather, &c.

PUMP, a machine for raising or water, operating in general on the pr that the air being exhausted from a pi lower end of which is in a reservoir of the water is pushed by the external pr of the atmosphere up this pipe, where various contrivances it is discharged higher level. Respecting the introdu pumps nothing certain is known. Wilk states that an instrument resembling a p pump is often represented in the sculptures the ancient Egyptians; but such a ma does not appear to have been used by nations of antiquity, nor by the Greeks Romans, nor by any rude nations of later The contrivances of the Asiatics for ra water are wheels furnished with buckets their periphery, the pole and bucket most ancient as well as modern use, and Archimedean screw. Several classes of are recognized, as lifting, forcing, rotary, centrifugal, distinguished from each other the different contrivances for exhaustin air and raising the water. The lifting the most simple form of the machine pipe itself is the working chamber, and it a piston furnished with a valve openin ward is made to move up and down. The e valve the air is forced up by the down oke, and is raised as the piston ascends. e water at the bottom follows the air into tube and through the valve till the weight the column counterbalances the pressure t pushes it. If a pump could be made with ton and valve working air-tight, the height the column of water thus raised should be t sufficient to counterbalance by its weight e atmospheric pressure; and this at the level the sea is 34 feet; but 28 feet is commonly e height which the water reaches. To nearly is height the water may be discharged through hole in the side of the tube, by merely taking the atmospheric pressure as described, or what is called suction, a portion of the water ing allowed to flow up through the piston, hich works below this opening. To raise it gher, the piston rod and tube are extended ward to any height, and the water, continu- y accumulating above the valve in the piston th each stroke, is at last raised to the outlet. prevent the water from flowing back as the ston goes down, a second valve also opening ward is set in the tube within a few feet of e bottom. With such pumps water is raised ore than 100 feet, sometimes even 200 feet, a single lift. (See MINE, vol. xi. p. 527.) e pumps used in houses for raising water the upper stories are lifting pumps, furnish- d with a side discharge pipe, rising above the orking barrel to the required elevation.—nother class of pumps is the forcing pump. this the piston, called the plunger, is with- t a valve, and works in a chamber through hich the water does not pass, but, entering below as the piston is raised, is forced t by the return stroke, passing from the ttom of the chamber into a side pipe rough a valve opening outward, and thence herever the pipe leads. The valve in the pply pipe opening inward, the water is pre- nted from flowing back through it. Double- ting forcing pumps have been made, the pply pipe and discharge pipe connected th the working chamber on both sides of e piston, so that as this is moved in either rection it draws water on one side and dis- arges it on the other. With an air chamber perfectly uniform flow is thus secured. The actical objection to this kind of pump is the ultiplication of valves in one machine, two of hich are required on each side of the piston. hese in all pumps are the parts that fail or get t of order. It is found better in practice to e two distinct pumps, one at each end of a ver beam, the piston of each acting in turn ith the descent of the beam. After this man- er fire engines are commonly constructed of o forcing pumps, discharging into a common r chamber. (See FIRE ENGINE.) Four pumps f these have also been made to work together, eir strokes following regularly in turn. Forc- g pumps of great power, such as are used for ising water in mines, which are occasionally ade to raise a column even 300 feet at one lift, are provided with a long solid plunger, which works in a tight stuffing box, but in the barrel immediately below this loosely. The rods of forcing pumps are outside of the lifts or pipes, entering only the working chamber. In large pumps they act by their weight, the power being exerted to lift them and not the water. In lifting pumps the rods usually pass through the whole height of the discharge pipe, which must be vertical, and the power is exerted to lift them and the column of water together.—ROTARY PUMPS. A great variety of pumps have been contrived of the rotary class. In these the piston is formed of one or more wings attached to a horizontal axis which passes through the ends of a very short cylinder. Revolving in this cylinder, the wings first produce a partial vacuum, and then propel before them the water that enters by the supply pipe. The varieties of this class of pump differ from each other in the contrivances by which the water is prevented from being carried round the entire cylinder and is forced up the discharge pipe. These are numerous, and many of them exhibit much ingenuity. One, invented about the year 1818, and known as the Massachusetts pump, resembles the blowing fan. Four wings or vanes are attached to an axis which revolves a little to one side of the centre of the cylindrical box, so that while the vanes on one side run close to the inner surface of the cylinder, the space that separates these grows larger round to the other side, till it opens into the discharge pipe, which goes off in a line tangent to the cylinder. The water is drawn in through an opening around the axle on each side, and being swept round rapidly by the revolving vanes is thrown up the discharge pipe. The impossibility of the vanes passing from the open space to the close space on the other side of the outlet without being followed by a portion of the water, evidently somewhat diminishes the economical working of this machine. The French have long employed a very ingenious rotary pump known as the *pompe rotative de Dietz*. In this the entrance and exit pipes enter close together on the same side of the cylinder, but the connection between them is round the annular space between the inner surface of the cylinder and the outer surface of a central drum. To this drum, which is carried by a belt or otherwise, are set in longitudinal slots 4 vanes or tongues as long as the cylinder, and dividing the annular space into 4 equal compartments. The tongues by the action of a spring within the drum are pressed out against the inner surface of the cylinder, and as they sweep round each one carries the water in the compartment before it forward to the place of discharge. The water can go no further round owing to the annular space being contracted on this side by a curved iron plate, which reduces the diameter of the cylinder the whole width of this space. The tongues running against this plate are pushed in even with the surface of the drum, and as the plate recedes on the other side of the place of discharge they are pressed out again, and water from the supply pipe flows in after each tongue, filling the compartment. A similar rotary pump, known as Cary's, has proved the most successful of this class of pumps in the United States. In another very old form of rotary pump the projections upon the drum are fixed and slope off like a wedge in the direction toward which they move. Each one in turn runs in under and lifts a rod which acts as the "butment" or dam to check the flow of the water round the annular space, and which immediately on the passage of the projection or vane drops back again, acting like a stamper when raised and dropped by a cam. The water in front of the butment is forced up a vertical pipe in which is a valve that prevents its return. At the great exhibition of 1851 comparative trials were made of different rotary pumps, among which those of Mr. Appold and Mr. Gwynne were regarded as the most efficient. In the former the rotating fan consisted of 3 circular plates a foot in diameter, the two outer ones 3 inches apart, and the third midway between these. Each outer disk was furnished with an opening of about 6 inches diameter around its axis for admitting the water in which it worked. The propelling vanes in the division on each side the central plate were 6 in number, and instead of standing straight out from the centre they curved back till they terminated nearly in a tangent with the circle that would circumscribe them. In comparing the working of this pump with curved, with straight radial, and straight inclined arms, the last set back at an angle of about 45°, the percentage of effect to the power exerted was found in a lift of about 18 feet to be for the first form 65, for the second 24, and for the third 43. All the tests showed that a great advantage was gained in the use of curved vanes. The number of revolutions of the fan per minute in these trials was from 620 to 870. Pumps of this character are adapted only for moderate lifts, rather under than over 20 feet. They have the advantage of great portability, are easily set up in any place, and are competent to discharge large volumes of water at low elevations with great economy. They are not obstructed by mud and gravel, which might be destructive to a pump with valves. They have proved especially serviceable for large draining operations, pumping out coffer dams, &c. One was constructed in England for draining, with a wheel 4½ feet in diameter, and run with an average velocity of 90 revolutions per minute; it raised in the same time about 15,000 gallons of water to the height of 4 to 5 feet. For further particulars respecting rotary pumps reference may be made to an article entitled "A Historical Review of the Centrifugal Pump," in the "Practical Mechanic's Journal," Sept. 1851, and the jury report of the exhibition of 1851.—A pump of entirely different character from any of those named, and used to some extent in domestic wells, is the chain pump. It has also been in general use as a ship pump, particularly in large ships belonging to the navy. An endless chain carrying a series of hollow pistons or buckets, which are adapted to pass through a pipe, is suspended upon a wheel at the top of the well, and passes around another under the surface of the water below. As the upper wheel is turned by a crank its teeth catch in the links of the chain and raise the full buckets on one side, which are discharged at the top as they turn over, and go down empty to be refilled. The recommendation of this pump is the convenient method of working it by turning the crank. It is, however, on account of the continual loss of water in ascending, not economical in its application of power.—Pumps for the use of ships, of which many kinds are now employed, are necessarily constructed with particular reference to the danger of their being obstructed by the loose materials that are likely to be floating in the bilge water, such as chips, oakum, or grain, or other articles derived from the cargo. The pipes are large and capacious, and the valves are made to drop freely into their seats. It is moreover important that they should be accessible for removing any obstruction with the least possible loss of time.—The most powerful pumps in use are those employed for draining deep mines, and, as stated in the article **Mine**, already referred to, they, as well as the pumping engines, have been brought to their greatest perfection in Cornwall, where their improvement has been long stimulated by the system of periodically publishing the performance of the principal machines. They have thus become of interest not merely as draining machines, but as measurers of the work performed by the steam engines; and this being in the way of the regular work of these engines, they are the best practical dynamometers. The use of Cornish pumps and engines is not however limited to mines, but they are now applied to supplying water for the use of towns, having been introduced first in London in 1839 by Mr. Thomas Wicksteed, an eminent hydraulic engineer, since which time they have been generally recognized as the standard machinery for this purpose. On this account a more detailed notice of them and of the work of some American pumping engines may be appropriately introduced. The use of the Cornish lifting pump is mostly limited to taking water from the bottom of shafts while these are sinking. When the shaft has reached a depth of 100 to 150 feet below the level of discharge of the water, a reservoir is constructed to one side in the rock at the bottom, and a forcing pump is permanently set to force the water up to the outlet, and the lifting pump is made to commence anew and follow the shaft as it is sunk 100 or 150 feet deeper. The superiority of the lifting pump for use in sinking consists in its being more easily moved and adjusted than the forcing pump, and in its greater efficiency as a suction pump, raising the water from greater depths to the level of its working chamber. The forcing pump would otherwise be preferred, because the weight of its rods, which must at any rate be lifted, is applied in descending to forcing up the water, and because it is more easily kept in order, the pump rods being external, and not concealed in the pipe, and moreover not obstructing the flow of water by partially filling the ascending pipe. The lifting pump is of various dimensions, from 6-inch to 16-inch bore of pipe. This is made in lengths of 9 or 10 feet, which are added one after another upon the top as the pump goes down. The bottom length, called the windbore, stands upon the rock in the bottom; and to resist the blows and shaking from the blasts exploded around it, this piece is made of the strongest mixture of cast iron, and the shell is not less than 2½ inches thick. The lower end is not open, but rounded off and perforated with holes for straining the water. The diameter is large enough to admit the next upper length, and an accurate fit is made by boring and turning these two pieces, so that the lower one may slide down 9 feet and keep the connection perfect while the upper remains fixed. The upper connects above with the "door piece," a chamber 2 feet or more square, in the bottom of which the lower valve is seated. One side of this chamber is closed with a movable plate, strongly secured by screw bolts, which being removed, the interior is exposed and access is had to the valves. The lower valve is a circular box with tapering sides made to fit closely in its seat, and it has either a single large clack or two small ones hinging near the centre. The clacks are metallic plates lined with sole leather. Upon the top of the door piece the working barrel may be bolted down, or an intervening circular chamber may be introduced, the diameter of which gradually contracts upward to that of the working barrel, which is then bolted upon it. This barrel is bored perfectly smooth within, that the piston may move up and down with a uniformly accurate fit, and its diameter is an inch or more less than that of the discharge pipes that succeed it above. The bucket, or valve, attached to a strong iron rod (the continuation below of the wooden rods that go up to the surface), is packed like the piston of a steam cylinder, and is provided with either one or two clacks. It is reached for repair or replacing either by letting it down into the chamber or raising it up through the pipes to the top. The pipes above are carefully added one upon another in a perfectly vertical line, each length being of 9 feet and secured upon the one below by bolts through the flanges with which the pipes are furnished at each end. The thickness of the metal in these pipes is usually 1½ inches. The pump rods, in straight lengths about 4 inches square, are added on at the top together with the pipes, the joints being spliced by a sort of dovetailing and secured by long wooden strips at the sides, the whole strongly bolted together. The joinings must be skilfully made so that the rod shall hang in the centre of the pipes the whole way down. The discharge at the top is into a wooden box and spout fitted around the upper pipe under the flange.—The forcing pumps for large operations are of much greater range in their dimensions than the lifting pumps, the working barrel and main discharge pipe of some of them amounting to 73 inches[*] in diameter. The pump itself consists of the working barrel, a chamber or door piece below this, and the suction piece with its valve as in the lifting pump on the same vertical line. But the working barrel is not continued upward into the discharge pump. A plunger of nearly its full diameter enters it at the top through a stuffing box, and moves up and down with a stroke of 6 to 12 feet or more, according to the size of the pump. From the chamber the water, forced out by the down stroke, passes into an adjoining apartment on one side, and thence up the ascending pipe, which is bolted on this apartment by the side of the working barrel, which is bolted on the other. The air chamber for giving uniformity to the flow is connected with this pipe. The rod from the working barrel may pass up directly to the lever beam of the steam engine, or be secured at any convenient distance up the shaft to a main rod working other pumps on different levels. The application of steam power to work forcing pumps is after the same plan in mining operations and in water works for supplying cities. The steam, admitted to but one side of the piston of the steam cylinder, acts directly, or by the lever beam, to lift the weight of the pump rods; or if this is not sufficient to counterbalance the weight of the column of water and the friction, and move moreover with the required velocity, more weight is added in the plunger. By this arrangement the column of water is not set suddenly in motion by a rush of steam, the force of which gradually diminishes toward the end of the stroke; but starting slowly the descending weight gains velocity, till the piston is received at the end of the stroke against the elastic cushion of steam in the head of the cylinder.—In the United States forcing pumps of very large dimensions are employed at the water works of many of the cities, and these are driven by pumping engines of remarkable efficiency. (See AQUEDUCT.) These were chiefly made by the most competent engineers in the country, who have vied with each other to produce engines that should exceed the Cornish in simplicity, cheapness, and durability, and equal them in economy of performance. Among the largest of these are the Cornish engines at the Fairmount water works, made in Philadelphia, and others at Belleville, N. J., made at Cold Spring, N. Y.; and of the American, the crank cam engine at Hartford, the double direct-acting engine at Brooklyn, N. Y., both built at Hartford, and the direct-acting double cylinder engines at Cambridge, Mass., built by Mr. H. R. Worthington of New York. Of these trials have been made under the direction of a board of distinguished engineers specially appointed for the purpose of determining their comparative capacities. The results of their investigations were presented in a "Report on Trials of Duty made in 1857 and 1859 upon the Brooklyn, Hartford, Belleville, and Cambridge Pumping Engines," from which the following summary is obtained. Expressed according to the formula of duty adopted in Cornwall, the Brooklyn engine raised 60,798,200 lbs. one foot high with 100 lbs. of coal; the Hartford, average of two trials, 58,865,115 lbs.; the Cambridge, 71,278,486; the Belleville, average of 3 trials, 71,062,545 lbs. Some allowances warranted by the circumstances having been made, the engines were finally rated in the following order of merit:

---

[*] An engine with 8 pumps of this size was ordered by the Haarlem Meer commissioners, after satisfactory operations of the [illegible] inch pumps, noticed in the article DRAINAGE, vol. vi., p. [illegible]

Engines.	Lbs. lifted 1 ft. high with 1 lb. of coal.	Duration of trial, hours.
Cambridge, 1st trial	669,411	9
" 2d "	675,746	14¾
Hartford, 1st trial..........	614,426	17¾
" 2d "	646,994	12
Belleville (Cornish).........	628,288	12
Brooklyn..................	601,407	26
Spring Garden, Philadelphia (Cornish)................	589,053	48

The last was an independent trial made in 1856 by another engineer before these investigations were proposed. Though the results fall short of the duty of the Cornish engines working under the most favorable circumstances at the mines in that particular service for which they were specially designed and adapted (see MINE), it is well understood that, if subjected to the same severe methods adopted in these trials, no essential superiority would be found in the working of the Cornish engines.—Pumps are employed to feed steam boilers with water, forcing it in against the head of steam. Each engine is supplied with such a pump, and to economize fuel the water employed is the hot water from the exhaust pipe. The plunger is connected with the lever beam of the engine, or with a crank upon one of the shafts, and the sliding valves for admitting the water and regulating its exit are also moved by the machinery of the engine. The need of an independent steam pump for this purpose, which might be set in operation at any moment, whether the main engine were working or not, and which moreover might be conveniently applied to other purposes, as a pump for raising water, as a fire engine, &c., has led to the invention of some of the most efficient and useful pumps. The best and most extensively used is the steam pump patented by Messrs. Worthington and Baker of New York in 1849, now much improved by Mr. Worthington in what is called the duplex pumping engine. The original pump is of itself a small horizontal high pressure engine, fed directly from the boiler, and constructed like other engines of this character, so far as need be to obtain the alternate movement forward and backward of the piston rod. This rod is prolonged from the steam cylinder, and within a distance of one to two feet it enters the forcing pump, which is set directly on a line with the cylinder and upon the same support. The rod terminates in the plunger of the pump, which is fitted to a bore of smaller diameter than the steam cylinder. By this arrangement any pressure of steam applied to the steam piston must be effective to drive this forward and carry the plunger of smaller area against the same pressure. Thus with each stroke a small quantity of water is propelled into the boiler by the expenditure of the larger bulk of steam. The efficiency of the pump is increased by the plunger being made double-acting, and by an ingenious arrangement of the water valves over the pump, which are exceedingly easy of access and adjustment. From the valves the water passes into an air chamber, whence it is delivered in a continuous stream. The contrivance for sliding the valve in its seat upon the upper side of the steam cylinder is simple and ingenious. Upon the piston rod, half way between the two cylinders, is fixed an upright arm, which is carried each way with the piston. At its upper end it slides along the valve rod, and at the end of each stroke it hits a tappit or nut on this rod with sufficient force to move the valve. To insure this being always carried far enough, so that it shall not stand directly over the passages for the steam and exclude this from both ends of the cylinder, the water passages in the pump are so arranged, that at or near the end of the stroke the resistance of the water is reduced and the plunger slips instantly forward till checked by the action of the steam in the steam cylinder. These pumps are employed in numerous large manufactories and distilleries for pumping water and other fluids; and in open quarries they have proved a very convenient and powerful means of drainage, the pump being set in the bottom, while the steam may be conveyed to it from boilers at the top of the bank or other point.—The improvement is designed to counteract the thumping action of the piston, which sometimes takes place when the pump is worked too rapidly and under great pressure—a result of the momentum of the piston, similar to that which occurs with the weighted plunger of the Cornish pump. To produce an even, smooth, reciprocating motion at any desired speed, two double-acting pumps are employed together with their two steam cylinders, all seated firmly together in an iron casting called a cradle. The two steam cylinders are supplied with steam independently of each other; and the slide valve of each of them, which controls the admission and exit of the steam, is moved not by the action of its own piston rod, but by that of the other cylinder

der, with which it is connected by a rock shaft. By this arrangement, before the stroke of one cylinder is completed its piston rod opens the valve of the other cylinder, and a continuous motion is thus kept up. Each piston reposes for a perceptible interval at the termination of the stroke, during which quiet time the water valves drop to their seats by gravity, instead of being forced down as is usually the case by the return motion. The current of water in the supply pipe is moreover always unchecked, one chamber of the pump being ready to receive it before the other is shut off. The beneficial effect of this is to render the machine almost noiseless, removing all concussive action, together with the usual causes of rapid wear. The principle has been successfully applied to high pressure and condensing pumping engines of all sizes. The water works for supplying the city of Harrisburg, Penn., are furnished with pumps of this character, the working of which has proved very satisfactory.

PUMPKIN. See Gourd.

PUNCH, or Punchinello, a humorous character in a species of puppet show exhibited on the Italian stage and in the streets of European cities. The name is supposed to be a corruption of *Policinella* or *Pulcinella*, which in turn, according to Galiani in his *Vocabolario del dialetto Napolitano*, was derived from Puccio d'Aniello, a peasant, whose humorous eccentricities were in the 17th century transferred to the Neapolitan stage, where he has continued to be the medium of local and political satire, and a favorite conventional character in the Italian exhibitions of *fantoccini*, or puppet shows. The modern puppet show of "Punch and Judy" embodies a domestic tragedy followed by a supernatural retribution, the whole of which is treated in a broadly farcical manner. Punch himself is represented as a short obese personage, with an enormous hump on his back, a wide mouth, long chin, and hooked nose, and wearing a three-pointed cap. His wife Judy, who is in some respects his counterpart, and his dog Toby, are important characters in the performance.

PUNCH, or Punching Machine, a tool for striking holes in any thin material, as leather, iron, &c. In its simplest form it is a solid-pointed tool of steel, which is held in the hand and struck with a hammer. With this the blacksmith makes small holes in iron. For larger holes the punch is a circular hollow chisel, tapering to a sharp edge all around, and opening above in an annular space on each side through which the blanks or cylindrical bits cut from the material are discharged. Small punches for making holes in leather are fixed in one of the jaws of an instrument like pliers, and work against a copper disk attached to the opposite jaw. In an American improvement of this tool a set of 4 punches of different sizes are arranged in the form of a cross, and set so as to revolve in one of the jaws, either punch being brought into action as desired. For punching holes in the plates of steam boilers a great variety of powerful machines have been invented and are in use, some of which also combine the shearing of the plates with the punching. A very convenient portable punch for similar application is made of a bar of iron an inch thick and 4 or 5 inches wide, which is bent into the form of a horse shoe, and perforated in one of its ends for a screw, which at the outer end is square for the fitting on of a lever for turning it, and at the other end is pointed to act as a punch. On the face of the opposite jaw is set a steel ring or bed punch, and upon this is laid the edge of the boiler plate which is to be perforated. With this simple machine holes may readily be made of ¾ inch diameter in plates ⅝ inch thick; and it can be easily taken into the holds of steam ships or to work upon boilers in any situation.

PUNCTUATION, in grammar, the art of dividing a written or printed discourse into sentences and parts of sentences, for the purpose of indicating the mutual relations of the words, by means of points. The principal points used in English composition are the comma (,), semicolon (;), colon (:), period (.), note of interrogation (?), note of exclamation or admiration (!), dash (—), and parenthesis ( ). Of these, only the first four are marks of punctuation as the term is usually understood, or grammatical points indicating the length and character of the pauses to be made in reading. The others are mainly rhetorical or syntactical aids, regulating the modulation of the tone rather than the suspension of the voice; but the interrogation or exclamation point may take the place of either of the former, according to the structure of the sentence; and the dash partakes of both characteristics. The comma marks the smallest grammatical division in written or printed language. The semicolon separates such parts of a sentence as are somewhat less closely connected than those separated by a comma. The colon denotes a still longer pause than the semicolon. The period indicates the end of an assertive sentence which is independent of any that follows, and is also used after every abbreviated word, after headings, titles of books, &c., and generally after Roman numerals. The note of interrogation is placed after a question, and in Spanish is also placed inverted at the beginning of a question. The note of exclamation indicates an ardent wish, admiration, or other strong emotion, and is joined to interjections, words used as interjections, and clauses containing them; it is also duplicated in Spanish like the preceding. The dash is employed where a sentence breaks off abruptly and the subject is changed; where the sense is suspended, and is continued after a short interruption; where there is an unexpected or epigrammatic turn in the sentiment; after a long member, or series of phrases or clauses, leading to an important conclusion; before a word or phrase repeated in an exclamatory or emphatic manner—what elocutionists term an echo; where there is an ellipsis of such words as "namely" and "that is;" where there is an ellipsis of letters or figures, and in numerous other cases. Sometimes, as in this work, it is used instead of paragraphs. The parenthesis encloses a word or phrase introduced into the body of a sentence with which it has no grammatical connection.—Other marks in frequent use, and generally treated under the head of punctuation, though not strictly included in it, are the apostrophe ('), used to indicate the omission of a letter or letters, and also as a sign of the possessive case; the hyphen (-), placed between the constituent parts of a compound word, and at the end of a line when a word is divided; quotation marks (" "), placed at the beginning and end of extracted passages, of the speeches in dialogue, &c.; brackets or crotchets [ ], generally enclosing an explanatory phrase or passage inserted by one writer in a quotation from another; and references (consisting of the characters *, †, ‡, §, ‖, and ¶, called respectively asterisk or star, dagger, double dagger, section, parallel, and paragraph, or of figures or letters smaller than those of the text), pointing to notes correspondingly marked at the foot or margin of the page.—The ancients were in the habit of writing without distinction of either sentences or words until the 104th Olympiad. Afterward it became usual to place a mark of distinction at the end of every word, as in the following inscription found near Bath, England:

IVLIVS⊽ VITALIS⊽ FABRI, &c.

Sometimes, as in the subjoined extract from an inscription given by Montfaucon, a letter laid horizontally was used as an interstitial mark:

P. FERRARIVS HERMES
CAECINIAE ⊣ DIGNAE
CONIVGI ⊣ KARISSIMAE
NVMERIAE ⊣

There is reason to believe, however, that some system of punctuation was known to the Greeks in the time of Aristotle. It probably consisted of a single mark, which changed its signification according to a change of position. At the bottom of a letter (A.) it was equivalent to a comma; in the middle (A·), to a colon; and at the top (A˙), to a period; but this plan could only be followed as long as Greek manuscripts were written entirely in capitals. St. Jerome in his translation of the Scriptures used certain marks of distinction or division, which he called *commata* and *cola;* but it has been thought that they consisted simply in writing every clause on a separate line. The modern points came into use very gradually after the invention of printing, the comma, parenthesis, note of interrogation, and period being the earliest introduced, and the note of exclamation the last. The first printed books have only arbitrary marks here and there, and it was not until the 16th century that an approach was made to a regular system by the Manutii of Venice.

PUNDIT, or PANDIT (Pers. *pand*, learning), in Hindostan, a Brahmin who consecrates his life to the study and interpretation of the Vedas and Shastras, or all written law and knowledge. This word occurs in the Sanscrit, Hindostanee, and Persian languages, and is very nearly equivalent to doctor.

PUNJAUB (country of the five rivers), a territory of British India, occupying the N. W. extremity of Hindostan, and giving its name to a lieutenant-governorship lately formed out of the Punjaub and the Delhi division, including the districts of Paniput, Hurriana, Delhi, Rohtuk, Goorgaon, and the territories of Ferozepore, Loodiana, Umballa, and Kythul. The Punjaub proper is bounded N. by Koondooz, N. E. and E. by Little Thibet, Cashmere, and Ladakh; S. E. and S. by the North-Western provinces and Sinde, and W. and N. W. by Cabool; it extends from lat. 29° to 34° N., and from long. 71° to 7[illegible] E., and is of triangular shape, the sides being respectively 680 m., 630 m., and 500 m. long; area about 130,000 sq. m.; pop. 4,101,000. The chief towns are Lahore, the capital, Peshawur, Mooltan, Attock, and Dera-Ismael-Khan. The N. part is mountainous, being traversed by spurs of the Himalaya; but with these exceptions the surface is for the most part an extensive plain, gradually sloping from N. E. to S. W. in the direction of the 5 great rivers by which it is watered, which, uniting in the Punjnud, flow together to the Indus. These rivers are the Jhylum, Chenaub, Ravee, Beas, and Sutlej; they furnish an aggregate navigation of nearly 2,000 m., and divide the country into 5 districts or *doabs*. Gold is found in the sands of the Indus and Chenaub, and iron, plumbago, antimony, alum, and sulphur in the hill country; nitre is plentiful in the plains, and there are coal beds on the E. bank of the Indus.—The population is composed of various races, including Jats, Rajpoots, and Cathies, of Hindoo descent; about 250,000 Mohammedans, of Afghan descent; and Khalsas or Sikhs proper, who, though the dominant race, number less than a quarter of the inhabitants. The people are generally physically superior to those of other parts of Hindostan, and the Sikh soldiers are noted for bravery. The manufactures include silk and cotton goods and shawls of superior quality, second only to those of Cashmere; brocades, tissues, and carpets are also made; and firearms and swords of excellent temper were made in large quantities when the Sikhs ruled the country. An extensive trade is carried on with Cabool, Bokhara, Candahar, and different parts of central Asia. Public schools have been established for both sexes by the British, at which some 6 per cent. of the inhabitants receive instruction, exclusive of the private education which is general among the higher classes. The government under the present rulers resembles that established in the Bengal presidency. In 1849 the revenue was £1,560,000. Under the Sikhs the government was originally a sort of republic or confederation of *sirdars* or chiefs, all holding independent sway, and administering their own laws in their own districts.—Alexander the Great invaded the Punjaub. About A. D. 920 it was conquered by Mahmoud of Ghuznee, whose successors made Lahore the seat of their government. It afterward became subject to numerous chieftains, principally Afghans, who ruled it till the Mogul conquerors obtained possession of it in 1519. In 1748 it was overrun by the Afghans, to whom it was ceded by the Great Mogul in 1750. In 1768 the Sikhs made themselves masters of the territory E. of the Jhylum; and in 1809 Runjeet Singh conquered the greater part of the Punjaub, including the hill states, and afterward extended his authority over the whole of the country of the five rivers, and added Ladakh or Middle Thibet and Baltistan or Little Thibet to his dominions. In 1839 Runjeet was succeeded by his son Khurruk Singh, who died a few months afterward, when a period of anarchy followed, which ended in the Sikhs invading territory under the protection of the British. In 1845 were fought the battles known as those of the Sutlej, in which the Sikh forces were defeated with heavy loss, and the English took possession of the Punjaub and constituted themselves guardians of Dhuleep Singh, a minor, and grandson of Runjeet. In 1849 a conspiracy between several chiefs and the Afghans led to a second war with the English, in which the Sikh soldiers displayed their usual bravery, and their opponents suffered some heavy losses; but the result was the annexation of the Punjaub to the East India company's territory in March, 1849. In 1859 it was formed into a new lieutenant-governorship.

PUNTA ARENAS, the sole port of Costa Rica, on the gulf of Nicoya, established in 1847. As its name implies, it is situated on a sandy point projecting into the gulf. There is an outer and an inner harbor, the latter formed between the sand spit and the mainland, accessible only for vessels of very light draft. The former is an indifferent anchorage, protected by two islands from the swell of the Pacific. Vessels drawing more than 7 feet of water must anchor in the outer harbor 2 m. from the shore. The port is regarded as unhealthy, but not in the same degree as the other portions of the coast. The maritime commerce of the port for 1855 was as follows: vessels entered, 86; cleared, 67; value of exports and imports, $3,500,000. A good road leads from Punta Arenas to the capital of Costa Rica, San José, a distance of 75 m.

PUPA. See BUTTERFLY, and CHRYSALIS.

PURBACH, or PEURBACH, GEORG, a German astronomer, born at Peurbach, Austria, in 1423, died in Vienna in 1461. Having studied astronomy under Gmunden at the university of Vienna, he went to Italy to extend his knowledge of the science, and upon his return succeeded his master in the professorship at Vienna. At the time of his death he was reputed the first astronomer in Europe. He began a new edition of Ptolemy's *Almagest*, based upon the Latin translation from the Arabic; and though he neither understood Greek, in which the work was originally written, nor Arabic, his knowledge of astronomy enabled him to make his edition much better than previous ones. He left this work unfinished to his pupil Regiomontanus, who completed it. The most celebrated of Purbach's own works is his posthumous *Theoria Novæ Planetarum* (1488), which served as an introduction to Ptolemy, and as a text book.

PURCELL, HENRY, an English composer, born in London in 1658, died Nov. 21, 1695. He was the son of Henry Purcell, one of the gentlemen of the chapel royal, and probably received his first instructions in music from Capt. Cook, the master of the children of the chapel royal. Dr. Blow subsequently gave him a few lessons in composition, a circumstance considered of so much importance in the life of that musician that an inscription on his tomb specially mentions him as "master to the famous Mr. Henry Purcell." While a singing boy in the choir of the king's chapel, he composed several anthems still occasionally performed; and at the age of 18 he was appointed organist of Westminster abbey, a position which he resigned 6 years afterward to become one of the 3 organists of the chapel royal. He had previous to this time composed a number of anthems of great popularity; but notwithstanding his ecclesiastical training and occupations, his attention seems early to have been directed to secular and particularly to dramatic music. In 1677 he composed the music for an operetta by Tate, entitled "Dido and Æneas," performed by the pupils of a female boarding school. The success of this work encouraged him to become a regular writer for the stage, and for the play of "Abdelazar" (1677), for Shadwell's adaptation of "Timon of Athens" (1678), and Lee's "Theodosius" (1680), he composed the overtures and act tunes or pieces to be performed between the acts, and the incidental songs which it was then customary to introduce into plays. A number of these instrumental pieces in 4 parts were published by his widow in 1697, under the title of "A Collection of Ayres, composed for the Theatre and on other occasions, by the late Mr. Henry Purcell." Next in order of his compositions was a series of 12 sonatas for 2 violins and a bass published in 1683, and followed shortly afterward by another series of 10. Subsequent to this period he produced the greater part of his dramatic music, and an intimacy contracted between himself and Dryden led to his being employed to set the songs, dialogues, and choruses in several of the latter's most successful plays. In 1690 he composed new music for the "Tempest," as adapted for the stage by Dryden and Davenant, and within the next two years he similarly embellished Dryden's "King Arthur," "Indian Queen," and "Tyrannic Love." The first of these contains the duet, "Two daughters of this aged stream are we," and the charming song, "Fairest isle, all isles excelling."

The incantation scene in the "Indian Queen," commencing, "Ye twice ten hundred deities," in the opinion of Dr. Burney, opens with the best piece of recitative in the English language. For D'Urfey's 3 parts of "Don Quixote," produced in 1694–'6, he furnished perhaps the finest of all his dramatic compositions, the two songs, "Let the dreadful engines" and "From rosy bowers," the latter of which, it is said, was set in the author's last sickness. Within a few months before his death he also furnished the music for "Bonduca," a tragedy by Beaumont and Fletcher made into an opera by Dryden, and which the well known duet and chorus, "Britons, strike home," will preserve from oblivion. He also composed vocal pieces for Beaumont and Fletcher's "Diocletian," altered by Betterton, Dryden's "Aurungzebe," Shadwell's "Libertine," and other plays. In the "Fool's Preferment" occurs the song, "I'll sail upon the Dog Star," which Dr. Burney declares has all the fire of Handel's prime. The pieces above cited, together with the best of his detached and incidental songs, dialogues, and scenes, were published by his widow in 1697 under the title of "Orpheus Britannicus." His published anthems number 50, beside a celebrated *Te Deum* and *Jubilate*, with orchestral accompaniments; and his church music includes a complete service and a number of hymns and psalms. His odes, glees, catches, rounds, &c., were also numerous, and long held their popularity. Purcell died of consumption after an illness of some duration, and was buried in Westminster abbey. His dramatic compositions, on which his fame mainly rests, says Hogarth, "in variety of character, beauty of melody, truth and force of expression, and nice adaptation to the genius of the English language, are to this hour unparalleled. . . . . But the highest quality of his music is its genuine English character. In this respect it remains wholly unrivalled." For many years subsequent to the close of the last century Purcell's music was neglected or forgotten; but within the present century a revival both in the publication and the performance of it has been attempted with considerable success.

PURCHAS, Samuel, an English divine and author, born at Thaxted, Essex, in 1577, died about 1628. He was educated at St. John's college, Cambridge, and in 1604 was instituted to the vicarage of Eastwood in Essex. Removing to London, he received the rectory of St. Martin's Ludgate, and became chaplain to Archbishop Abbot. He compiled from more than 1,300 authorities a work entitled "Purchas his Pilgrimage, or Relations of the World, and the Religions observed in all Ages, and Places discovered, from the Creation unto this present" (1 vol. fol., 1613); and a collection of voyages under the title, "Purchas his Pilgrimmes" (4 vols. fol., 1625). The 3d and 4th volumes of this collection relate to America, and preserve the original narratives of the earliest English navigators and explorers of the western world. He also wrote "Microcosmus, or the History of Man" (1619), and "The King's Tower, and Triumphant Arch of London" (1623). It has been said that Purchas died in prison incarcerated for debts contracted in the publication of his "Pilgrimage" and "Pilgrims;" but this is denied by Wood, who says that he died in his own house.

PURGATORY, in the belief of the Roman Catholic church, a state of temporary suffering in the next world, where the souls of the just expiate the offences committed in this life. According to Catholic theologians, every sin, no matter how slight, deserves and will receive punishment either before or after death. The absolution of a priest in the sacrament of penance washes away the guilt of sin and remits the eternal punishment due for grave offences, but not the temporal penalty which has to be undergone as a satisfaction to God's justice. Baptism alone removes both the guilt and the penalty; and as few or no adult persons depart this life without having committed sins after baptism, there must be some middle state for such as do not deserve hell and are yet not pure enough to enter heaven. The church does not teach what is the nature and duration of the punishment of purgatory, nor that it is situated in any particular place. She believes that the sufferings of souls in the middle state may be abridged by indulgences, masses, and the prayers of their friends on earth; and one day in the year (All Souls' day, Oct. 2) is specially devoted to services and prayers for their benefit. The Greek church, like some of the eastern sects, prays for the dead, but does not believe in purgatory. Broughton has endeavored to prove that the notion of such a state was held by the Jews, pagans, and Mohammedans.

PURGSTALL, Hammer. See Hammer-Purgstall.

PURITAN, an epithet first applied in 1564 to English nonconformists, and which continued to designate them during the reigns of Elizabeth and the two first Stuarts. Such persons only as desired a wider separation from the Roman Catholic church than the established church of England seemed to afford them, and professed to follow the pure word of God, in opposition to traditions, human constitutions, and other authorities, were at first called puritans; but subsequently, says Sylvester, "the vicious multitude of the ungodly called all puritans that were strict and serious in a holy life, were they ever so conformable." In the latter part of Elizabeth's reign a portion of the nonconformists began to dispute the prevailing opinions concerning predestination, free will, and other doctrinal points, and under the arbitrary government of James I. and Charles I. all persons opposed to their maxims of government were classed as puritans; whence Hume has applied the name to three parties: the political puritans, who maintained the highest principles of civil liberty; the puritans in discipline, who were averse to the ceremonies and government of the established church;

and the doctrinal puritans, who rigidly defended the speculative system of the first reformers. Representatives from these three classes formed the bulk of the settlers of New England, and the union of them in the English civil wars effected the overthrow of royalty and the establishment of the commonwealth. At the time of the restoration the name became one of reproach, as implying an unreasonable degree of austerity in both temporal and spiritual matters. Since the relaxation in 1690 of the acts against the nonconformists, it has ceased to designate any particular religious sect. Of the Puritans who emigrated to North America, and whose influence has been so strongly manifested in the civilization of the continent, Bancroft says: "They were formal and precise in their manners; singular in the forms of their legislation; rigid in the observance of their principles. Every topic of the day found a place in their extemporaneous prayers, and in their long and frequent sermons. . . . . But these were only the outward forms which gave to the new sect its marked exterior. If from the outside peculiarities which so easily excite the sneer of the superficial observer, we look to the genius of the sect itself, Puritanism was religion struggling for the people."—The leading authority on the subject is Neal's "History of the Puritans" (edited by J. O. Choules, D.D., 2 vols. 8vo., New York).

PURKINJE, Johannes Evangelista, a German physiologist, born in Libochowitz, near Leitmeritz, Bohemia, Dec. 17, 1787. He was at first a monk of the order of the pious schools, then went to Prague to study medicine, and in 1819 became assistant professor of anatomy and physiology in that city, and in this position remained until 1823, when he went to Breslau as ordinary professor of physiology and pathology. In 1849 he returned to Prague. He has written numerous physiological works, and has also paid much attention to Slavic languages and literature.

PURPLE (Gr. πορφύρα; Lat. *purpura*), a color produced by the union of red and blue, and of various shades as one or the other of these predominates. The ancients esteemed it more highly than any other color, sometimes making it a distinctive badge of royalty, and again appropriating it to religious uses, as the decorations of the temple and the garments of the priests. In the Old Testament it is referred to in Exod. xxv. 4, xxxv. 6, xxxix. 29; 2 Chron. iii. 14; Jer. x. 9; Ezek. xxvii. 16, &c. It is however supposed that the purple of the Israelites was a scarlet, or even that the term was used generally for any color in which red predominated. The source of the true purple of the Greeks and Romans is noticed in the articles Buccinum and Murex; and in the article Mauve an account is given of the method of obtaining the beautiful and fixed purple dye known by that name, as practised by Mr. Perkins of England. The source of this color, recently introduced and now extensively used in dyeing and calico printing, is aniline, one of the products of the destructive distillation of bituminous coal. Other methods of treating the aniline, beside that of Mr. Perkins, are now employed for obtaining a color of this character. It is produced by adding acetic acid and bleaching powder to a saturated solution of aniline in water; and the shades are made to vary from blue to lilac by modifying the strength of the fluids employed. Aniline, in combination with acetic, sulphuric, or hydrochloric acid, is oxidized and made to produce the purple of various shades by treatment with different reagents, as peroxide of manganese, peroxide of lead, chloride of lime, or the green manganate of potash. By the last the purple color is precipitated and the liquid remains red. Silks and woollens absorb these purples without the use of mordants; but to dye or print vegetable fabrics with them mordants are required. In printing, the color is mixed with albumen and is finally fixed by steaming. Very fine purples of tolerably permanent character are also obtained from litmus. The so called "French purple" is produced by treating the lichens (which afford litmus) with an alkaline base, and precipitating from the filtered solution with an acid. The precipitate is moistened with sufficient ammonia to dissolve it. When boiled the solution is orange yellow, becoming red when exposed cold to the air. Heated in very shallow vessels to 100° to 140° F. it becomes violet, and will dye permanently silk or wool without mordants. By neutralizing the solution with an acid, a purple precipitate falls, which when separated and dried may be used for dyeing or printing. Various shades are obtained by combining with the precipitate carmine of indigo for violets, and carthamus or cochineal for reds.

PURPLE OF CASSIUS. See Cassius, Purple of.

PURSH, Frederic, an American botanist, born in Tobolsk, Siberia, in 1774, died in Montreal, Canada, June 11, 1820. He was educated at Dresden, came to America in 1799, and remained until 1811. In that year he visited England, where he pursued his studies, and in 1814 published at London an octavo volume entitled *Flora Americæ Septentrionalis*. Afterward he returned to America, and was engaged in the collection of materials for a flora of Canada when he died.

PURSLANE, the name of a succulent, fleshy, prostrate annual plant, formerly introduced into gardens for its use at table, but now seldom seen unless as a troublesome weed. There were several varieties, such as the golden, the green, and the white, which were carefully sown and cultivated as spinach is now. When fully grown, especially in a light rich soil, its stems and leaves are very palatable as boiled greens, and they have been used for pickling, or to garnish dishes. The common purslane (*portulaca oleracea*, Linn.) has an annual root, a stem 6 to 18 inches long, fleshy, smooth, spreading upon the ground, branching and rooting at intervals; the leaves thick and fleshy, half an inch long, alternate and opposite; flowers solitary, sessile, ephemeral; the calyx has 2 bluntly keeled sepals; the corolla has 5 petals of a pale yellow color; the seeds minute and numerous.—The common purslane represents the natural order *portulaceæ*, comprising both succulent herbs and shrubs with fleshy, entire, simple leaves, which are usually alternate, rarely opposite, and commonly destitute of stipules; the inflorescence terminal or axillary or solitary, and in spikes and panicles; the flowers regular, united, and usually short-lived; the fruit a 1-celled capsule, either opening longitudinally or transversely, and many-seeded, sometimes indehiscent and 1-seeded by abortion; placenta central; seeds albuminous, not winged, embryo curved. Several species of portulaca are known, chiefly natives of Asia and South America. The common purslane is supposed to have originated in the East Indies, though now extensively naturalized in Europe and America. Its properties are mild and harmless, though its seeds were once reputed anthelmintic. The *P. retusa* of Dr. Engelmann closely resembles it, and is found native west of the Mississippi. The hairy purslane (*P. pilosa*, Linn.) is a southern and western species, and native also of Mexico and South America. It is a low, diffuse plant, with lanceolate or linear leaves, having long tufts of hairs in their axils; flowers larger, crowded and sessile at the summit of the branches amid a dense tuft of hairs, with 5 purple petals and about 20 stamens. Several other species with terete leaves, pilose axils, and large showy flowers, have come into notice within a few years, and under floricultural care varieties of exceeding beauty have sprung from them; such are the *P. Gilliesii*, *grandiflora*, *Thellusonii*, *splendens*, &c., with crimson, purple, scarlet, rosy, white, yellow, striped, or variegated blossoms. They readily sow themselves after a year's cultivation, and will grow upon the driest and poorest soil, but flourish in the richer flower border, and are admirably adapted for bedding or sowing in large patches.—To this order belong the equally charming and interesting *calandrinia*, natives of the N. W. coast and California, with conspicuous purple flowers and thick glaucous foliage. The *talina* have low leafy stems, linear, cylindrical leaves, and cymes of purple flowers expanding for a single day. The terete-leaved talinum (*T. teretifolium*, Muhlenberg) is a pretty little plant occurring on rocks from Pennsylvania to the falls of St. Croix; it is capable of cultivation, and suited for rockwork where it can enjoy the full sunshine. The spring beauty (*Claytonia Virginica*, Linn.) is a perennial springing from a small tuber, has linear, elongated leaves, and rose-colored flowers of considerable size, from 6 to 15 in a loose raceme. It is a western and southern plant in rich moist woods, and grows well in the garden. There are 17 other species in North America, geographically distributed from New England to the pine woods near Fort Vancouver. The sea purslane (*sesuvium portulacastrum*, Linn.) and the *S. pentandrum* of Elliott are prostrate, maritime, succulent plants, with axillary or terminal apetalous flowers, and are found from the coast of New Jersey southward. The former has been employed for food as a substitute for New Zealand spinach.—The name purslane has been likewise applied to the euphorbias with which the true purslanes have no affinity; the spotted euphorbia or spotted spurge is called milk purslane, and another species bears the name of the black purslane, both common weeds by roadsides and in waste places.

PUSEY, Edward Bouverie, D.D., an English clergyman, born in 1800. He is the 2d son of the Hon. Philip Bouverie (who assumed the name of Pusey), younger brother of the first earl of Radnor. Having been graduated at Christchurch, Oxford, in 1822, he obtained a fellowship in Oriel college, took orders, and in 1828 became canon of Christchurch cathedral and regius professor of Hebrew in the university, a position which he still holds. He shares with Dr. Newman the reputation of originating the so called Anglo-Catholic movement in the church of England in 1833, which finds its best exponent in the celebrated Oxford "Tracts for the Times." Many of these, including an elaborate treatise on baptism, were written by Dr. Pusey, who also published letters in defence of his views to the archbishop of Canterbury and the bishops of Oxford and London. The characteristic tenets of the "Puseyite" party are judgment by works equally as by faith, baptismal regeneration, the apostolic succession of the clergy, the supreme authority of the church, the expediency of auricular confession and conventual establishments, and an efficacy in the sacraments of the church not inferior to that claimed exclusively by the Roman Catholic church. They aimed also at certain innovations in the ceremonies of public worship, and, in the words of the Rev. R. H. Froude, an ardent disciple of the party, wished "to unprotestantize the church," and called the reformation "a limb badly set, which required to be broken again." The agitation of these questions caused a violent controversy in the church of England, which has not yet died away. In 1843 Dr. Pusey preached a sermon before the university, in which he was understood to confess his belief in the doctrine of transubstantiation; and after an examination before a board of judges he was accordingly suspended from the office of preacher within the precincts of the university for 3 years. He was one of the editors of the "Library of Translations from the Fathers" and of the "Anglo-Catholic Library," and has adapted to the use of the church of England several Roman Catholic devotional works, and published sermons, treatises on the "Royal Supremacy in Spiritual Matters" and "The Ancient Doctrine of the Real Presence, gathered from the Fathers," and "Patience and Confidence the Strength of the Church" (1837). His most important work, the result of 50 years' study, "A Commentary on the Minor Prophets," is now publishing; 2 portions (Hosea—Amos, 4to., Oxford) have appeared (1861).

PUSHKIN, ALEXANDER SERGEIEVITCH, a Russian poet, born in St. Petersburg, May 26, 1799, died Feb. 10, 1837. He was educated at the imperial lyceum at Tzarskoe-selo, and on leaving it obtained an office at St. Petersburg in the department of foreign affairs; but having given offence to the government by his "Ode to Liberty" (1820), he was exiled from the capital and sent to fill a subordinate appointment under the governor-general of Odessa. The emperor Nicholas recalled him in 1825, and appointed him historiographer of Peter I., with an annual salary of 6,000 rubles. His acceptance of this position was regarded by the liberals as an abandonment of his principles. In 1829 he accompanied Field Marshal Paskevitch to Erzeroum. He died from a wound received in a duel. His first poem, "Ruslan and Lyudmila," was written at the age of 21; it is a story of the half fabulous time of Vladimir, and was from its first publication very successful. His *Plennik Kavkaskoi* ("Prisoner of the Caucasus," 1822) is a vigorous and somewhat fragmentary sketch of the escape of a young Russian captive from the Circassians. For his next poem, the "Fountain of Bakhchisserai," he received 3,000 rubles; it is a story not unlike "The Corsair" of Lord Byron. Between 1825 and 1828 appeared the various parts of "Eugene Onegin," a novel in verse, which is considered his masterpiece. His other works are: the "History of the Insurrection of Pugatcheff" (1827), written in discharge of his duty as historiographer; "The Gypsies" (1827) and "Poltowa" (1829), both narrative poems; "Boris Godunoff" (1829) and "The Stone Guest" (1826), dramatic poems; "The Captive's Daughter," a novel; and numerous tales and general miscellanies published in the *Sovremennik* ("Contemporary"), a quarterly miscellany, which he established in 1836. His "History of Peter the Great" was never finished.

PUSTULE, MALIGNANT, a specific disease, essentially septic and gangrenous, confined to the cutaneous tissue, and generally to those parts of the surface that are habitually uncovered. It appears most commonly on the face, and next on the hands, neck, and arms. It first appears in the form of a painful swelling, which, after a lapse of time varying from one to three days, rarely more, develops upon its central part a small reddish or purple spot, accompanied with itching. In the course of 12 or 15 hours more this spot changes into a bleb or vesicle, not usually larger than the head of a pin, containing a reddish brown or yellowish fluid. Owing to continued itching, the vesicle is ordinarily ruptured soon after its appearance; if otherwise, it dries up in about 36 hours, leaving the exposed dermis dry, and generally of a livid color. Itching now ceases; and, after a time varying from a few hours to a day, the centre of this discolored and denuded surface begins to grow hard and becomes surrounded by an inflamed areola covered with numerous small vesicles similar to the vesicle which first appeared. The middle of this areola is depressed, and the color varies from yellow to black. It is now hard in the centre and more painful than at any other stage. It is however a remarkable feature of malignant pustule that severe pain is generally absent; and this character, so different from all other acute inflammations of the skin, is a valuable negative diagnostic of the disease. During the next 24 or 48 hours the subcutaneous tissue becomes involved; the tumor strikes deeper and rapidly extends in all directions, yet it is so indurated as to be easily circumscribed, and its confines determined without difficulty. Meanwhile the central point, now of brown or livid hue, exceedingly hard and insensible, becomes gangrenous. If the disease ceases to make further progress, an inflamed circle of vivid redness now surrounds the gangrenous portion; the tumefaction, which had before rapidly extended, diminishes; and the patient experiences something like an agreeable warmth accompanied by a pulsatory motion of the affected part. The pulse, which had before grown irritable and feeble, revives; strength increases; if there has been some degree of fever, as occasionally happens, it is now resolved into a gentle perspiration; suppuration sets in between the living and the dead parts, and the detachment of the gangrenous portion leaves a suppurating surface of variable extent in different cases. Should the disease on the contrary tend to an unfavorable issue, generally no suppuration takes place; the gangrene spreads rapidly from the centre to the circumference of the tumor; the pulse becomes smaller and more contracted; the patient complains of extreme lassitude with inability to sleep, is attacked with fainting fits, and becomes passive as to the result; there is disinclination to take food or medicine, or have any thing done, and a total loss of appetite; the tongue is dry and brown; the features shrink; the skin is parched; the eyes are glassy; cardialgia and low delirium premonish the fatal termination. Such are in general the ordinary phenomena of malignant pustule, usually terminating in a period of time varying from 5 to 8 days. Exceptional fatal cases have been recorded however, varying from 24 hours to 16 days. In the suddenly fatal cases, the forces of the constitution are so quickly and entirely subverted by the malignancy of the disease, that few symptoms are manifested; the powers sink under it, as it were, without resistance. It is most fatal when attacking the face or neck. —Another variety of malignant pustule, which commonly attacks the hands or arms, is of a less regular character, in some cases presenting an appearance and running a course very similar to a circumscribed phlegmon, while in others it is exceedingly violent and fatal in a few hours, and in others still runs on for several weeks, and finally proves fatal rather from the effects of the disorder than from the disease itself. In the majority of these cases there is intense local pain in the affected part from the commencement, with enormous swelling and more or less redness. A small vesicle or pustule forms in the centre, and proceeds to take on a gangrenous character. Sometimes it becomes circumscribed and limits its action to the skin; but at other times numerous phlyctinæ cover the surface, and the destructive inflammation burrows into the cellular tissue which envelops the muscles, completely surrounding and disintegrating these organs, which become soft, black, and gangrenous. The blood vessels and nerves also become involved, and as a necessary consequence the death of the part ensues.—The pathology of malignant pustule is distinguished by a fluid state of the blood, which is usually very dark-colored; the texture of the heart is softened, and its surface covered with ecchymosed spots; the veins are sometimes softened and ecchymosed, and usually contain black or yellowish white clots of blood, of gelatinous consistence. The lungs are covered with superficial ecchymoses, presenting over their surface a number of deeply penetrating black spots, produced by local sanguineous infiltration. The inner coat of the stomach and intestines presents in different places, corresponding to the course of the vessels, prominent, dark-colored spots, formed by blood effused between the inner coats and the peritoneal covering. The villous coat of the stomach is also occasionally found ecchymosed; the liver and spleen are gorged with dark-colored blood, and the kidneys surrounded by emphysema.—*Causes.* It is the general conclusion of persons who have investigated the nature of malignant pustule, that the germ of the disease consists in an animal poison, usually contracted by man from cattle or their remains. In support of this view, it is found that as a general rule the disease most frequently occurs among knackers, tanners, veterinarians, persons engaged in the removal of offal, and stevedores, particularly those employed in handling hides from certain districts and countries where the diseases of cattle most prevail. In other cases it has been attributed to eating diseased animal food. Yet, strange as it may appear, in the whole scope of veterinary medicine no disease has been observed which accurately resembles the malignant pustule of man. Certain herbivorous animals, especially beasts of pasture, are subject to a disease called malignant carbuncle, characterized by the occurrence of a large uncircumscribed emphysematous tumor, which yields to pressure and crepitates under the fingers, and exhales a peculiar putrid odor. In its progress it turns black in the centre, and appears as if burned or charred; it is infiltrated with a yellowish colored fluid, and distended with a [illegible] gas. This disease is capable of being transmitted from one animal to another by inoculation, and by absorption to man, in whom it [illegible] a violent and dangerous course. MM. [illegible] and Manoury of France have vainly attempted to limit the term malignant pustule to [illegible] disease only. Malignant carbuncle and [illegible] ulcers which occur in cattle are the [illegible] tive symptoms of grave febrile disorders depending upon a diseased state of the blood and always consecutive to the febrile symptoms and the inoculation of man with matter from such an ulcer is only equally dangerous as the blood, and possibly the milk, of the same animal in the febrile state before the ulcer appeared. Indeed, cases have occurred where the blood of animals not previously known to have been diseased, has caused malignant pustule in man by absorption. It is the opinion of some observers that malignant pustule may occur spontaneously, without [illegible] contact with poisonous animal matter. [illegible] from the fact that diseased animal matter is known to cause the great majority of cases, many ways will readily suggest themselves [illegible] which inoculation might take place without any knowledge of the circumstance on the part of the person affected. A favorite dog or [illegible] (animals not subject to the disease) might [illegible] transport it; a butcher's knife or hook might convey the poison from diseased to otherwise healthy meat; or even a fly might carry on its tiny feet all that is necessary for a fatal inoculation. As a general rule, cattle which feed on prairie meadows are exempt from malignant disease; while those which are fed upon dried clover, lucern, and vetch, are peculiarly liable to carbuncle. The same may be said of cattle that are fed upon semi-decomposed grain, the refuse of distilleries and breweries. All such things are actively predisposing agents to the blood diseases of cattle, and liable to engender malignant pustule in man.—*Treatment.* Promote suppuration in the pustule as rapidly as possible, and sustain the constitution. To this end, as soon as the nature of tho disease is ascertained, the vesication formed on its surface should be opened, the fluid contents removed, and the denuded part covered with a dossil of lint dipped in a strong solution of muriate of antimony or other caustic. Six hours afterward this may be removed and a poultice applied; and 24 hours after this, if pain and burning heat have nearly or quite ceased, and no areola has formed, it may be safely concluded that the caustic has effectually permeated the whole of the diseased tissue, and that it will proceed to a healthy suppuration by the continued application of poultice. But if, on the contrary, a hard and deep-seated painful tumor has formed around the primary seat of the vesicle, we may take it for granted at the disease is extending itself. The tumor ould be forthwith divided through its whole idth and depth by a crucial incision, the ganrenous parts removed if any have formed, and e nitrate of silver or fused potassa thoroughly plied to the freshly divided surfaces. This roceeding is equally requisite when the slough hich forms on the centre quickly becomes rd and impermeable, like a piece of dry de; this must be removed to admit of the nimpeded action of the caustic. Scarifications nd cauterizations, with the continued applicaion of poultice, should be repeated daily until ppuration is established, or until the extent f the pustule is clearly defined. Internally, he bowels being first cleared by a mild catharic, quinia (4 or 5 grains every 3 or 4 hours), ith wine or brandy, and as much food as the atient can be induced to take (there being enerally disinclination to take food), and opites with camphor, as much as may be necesary to allay pain and produce sleep, constitute he basis of treatment. In spite of every ing, the peculiar contagion of malignant pusle, being in the blood, frequently proceeds traight on to a fatal termination; and this is ometimes the case even when the pustule eems to have been checked in its progress. On ecovery from malignant pustule, the deformties consequent upon its ravages sometimes equire surgical operations for their relief.—*istory.* Malignant pustule was not unknown o the ancients. Celsus and Paulus Ægineta oth described it under the head of carbuncle. Ambroise Paré, in the 16th century, distinuished it from plague. Yet it was not until he latter part of the 18th century that phyicians began to appreciate its nature. Thonassin, Boyer, Fournier, Montfiels, Veson, Sanerotte, Chambon, and especially Enaux and haussier, contributed to make the medical world acquainted with the nature of malignant ustule. During the present century, Bayle, Bidault, Villiers, Reynier, Rayer, Branell, Wager, Raimbert, Manoury, and Salmon, and reently Bourgeois and Gaujot, have given valuale monographs of cases and epidemics. In he United States, it has at least twice preailed epidemically—in the vicinity of Philaelphia in 1834–'6, and in Louisiana in 1837–'9. It is also said to have prevailed in Louisiana at n earlier period, soon after its settlement by he French. It is not known to have occurred in the northern portion of the United States otherwise than sporadically; unless, possibly, he "malignant erysipelas" which prevailed in he northern part of the state of New York in 1825 was a variety of malignant pustule; it was immediately preceded by a fatal epizootic of slavers among horses. In the same region, and just subsequent to an epizootic mong horned cattle in 1842, there were several cases of genuine malignant pustule, yet no one seems to have recognized its source. Since hat time, and it may be added since the commion practice of feeding cattle on the refuse of distilleries and breweries, and the more general spread of epizootic diseases, particularly in the northern part of the United States, malignant pustule has become a more common disease. Both of the epidemics above referred to were in conjunction with epizootics. Essays have been published in the United States by Drs. W. M. Carpenter, C. W. Pennock, J. H. Baldridge, and Wainwright; and sporadic cases have been described by Drs. E. D. Ayres, J. B. Wilkinson, Pierson, A. N. Bell, D. C. Enos, C. E. Isaacs, D. Dana, E. M. Snow, S. B. Wells, J. J. Ellis, and J. F. Noyes.

PUTNAM, the name of counties in 9 of the United States. I. A S. E. co. of N. Y., bordered W. by the Hudson river, E. by Connecticut, and watered by Croton river and Peekskill creek; area, 234 sq. m.; pop. in 1860, 14,002. Its surface is mountainous, a number of ranges crossing the county from S. W. to N. E., and the deep valleys which lie between are fertile. There are several beautiful mountain lakes, the principal of which are Mahopac, Canopus, and Gleneida. Iron, granite, limestone, and other minerals are found in the mountains, and there are many mines and quarries, some in operation and others that have been abandoned. It contains the West Point foundery, in the village of Cold Spring, one of the most extensive establishments of the kind in the United States. The works consist of a moulding house with 3 cupola furnaces, a gun foundery with 3 air furnaces, 2 boring mills, and several shops connected with them. From 400 to 600 men are employed. The productions in 1855 were 224,259 bushels of wheat, 64,504 of potatoes, 27,158 of apples, and 493,696 lbs. of butter. There were 31 churches, and 4,976 pupils attending public schools. It is traversed by the Hudson river and the New York and Harlem railroads. Capital, Carmel. II. A W. co. of Va., touching the Ohio with its W. corner, intersected by the Great Kanawha, and drained by its tributaries; area, about 350 sq. m.; pop. in 1860, 6,301, of whom 580 were slaves. It has a rough and hilly surface and a generally fertile soil, and contains extensive beds of iron ore and bituminous coal. The productions in 1850 were 249,040 bushels of Indian corn, 50,079 of oats, 14,373 of wheat, 37,122 lbs. of tobacco, 10,468 of wool, and 59,862 of butter. There were 6 grist mills, 8 saw mills, and 13 churches. Value of real estate in 1856, $1,048,982, showing an increase since 1850 of 46 per cent. Capital, Winfield. III. A central co. of Ga., bordered E. by the Oconee, and drained by Little river and several creeks; area, about 350 sq. m.; pop. in 1860, 10,130, of whom 7,142 were slaves. It has a nearly level surface, abounding with forests of oak and pine, and a soil naturally fertile. The productions in 1850 were 392,821 bushels of Indian corn, 45,205 of oats, 63,089 of sweet potatoes, and 8,621 bales of cotton. There were 1 cotton factory, 8 grist mills, 6 saw mills, 4 tanneries, 12 churches, and 197 pupils attending public schools. Capital, Eatonton. IV. An E. co. of Fla., bounded S. by St. John's river, and drained by its tributaries; area, about 450 sq. m.; pop. in 1850, 687; in 1860, 2,712, of whom 1,047 were slaves. Its surface is low and level and soil fertile. The productions in 1850 were 4,610 bushels of Indian corn, 32 bales of cotton, 74 hogsheads of sugar, and 7,030 gallons of molasses. Capital, Pilatka. V. A N. co. of Tenn., drained by affluents of Cumberland river; area, about 500 sq. m.; pop. in 1860, 8,558, of whom 682 were slaves. It has a hilly surface, and much of it is covered by forests. It has been recently formed from Jackson and White counties. Capital, Monticello. VI. A N. W. co. of Ohio, drained by Auglaize river and its tributaries, the Ottawa and Blanchard's fork; area, about 400 sq. m.; pop. in 1860, 12,808. It has a level surface, is covered with large tracts of timber, and its soil is fertile. The productions in 1860 were 189,165 bushels of Indian corn, 68,853 of wheat, 31,723 of oats, 4,478 tons of hay, and 15,123 lbs. of wool. There were 2 grist mills, 7 saw mills, 11 churches, and 3,068 pupils attending public schools. It is intersected by the Dayton and Michigan railroad. Capital, Kalida. VII. A W. co. of Ind., drained by a branch of Eel river and several creeks; area, 486 sq. m.; pop. in 1860, 20,729. It has an undulating surface and fertile soil. The productions in 1850 were 1,813,209 bushels of Indian corn, 82,965 of wheat, 81,423 of oats, 5,015 tons of hay, and 85,837 lbs. of wool. There were 10 grist mills, 11 saw mills, 9 newspapers, 62 churches, and 4,311 pupils attending public schools. It is intersected by the Indiana and Illinois canal, and the Indianapolis and Terre Haute and the New Albany and Salem railroads, both of which pass through the capital, Greencastle. VIII. A N. co. of Ill., intersected by the Illinois river and drained by its branches; area, 200 sq. m.; pop. in 1860, 5,587. It has an undulating surface and fertile soil. The productions in 1850 were 279,260 bushels of Indian corn, 88,771 of wheat, 29,671 of oats, 8,732 tons of hay, 10,774 lbs. of wool, and 48,494 of butter. There were 6 grist mills, 8 saw mills, 8 churches, and 880 pupils attending public schools. It is intersected by the Illinois central railroad. Capital, Hennepin. IX. A N. co. of Mo., bordering on Iowa, bounded E. by the Chariton river and drained by its branches; area, about 300 sq. m.; pop. in 1860, 9,208, of whom 31 were slaves. It has an undulating surface, diversified by prairies and forests, and a fertile soil. The productions in 1850, since which its population has very largely increased, were 49,940 bushels of Indian corn, 680 of wheat, 2,020 of oats, 2,208 lbs. of wool, and 9,843 of butter. There were 200 pupils attending public schools. Capital, Putnamville.

PUTNAM, Israel, an American general in the revolutionary war, born in the part of Salem now constituting the town of Danvers, Mass., Jan. 7, 1718, died in Brooklyn, Conn., May 19, 1790. He was the 11th in a family of 12 children, and in his boyhood was noted for his physical strength and bravery; but his literary advantages were not great, nor were the few he possessed very zealously improved. As soon as he was out of his minority he removed to Pomfret, Conn., where he bought a farm. Here occurred the famous encounter with the she wolf, which made the name of Putnam at once well known throughout the country. This animal had for years ravaged the property of the farmers in that region, and in one night had destroyed 70 sheep and goats from Putnam's flock. A strong party of the residents of the neighborhood at last resolved to continue the pursuit of the wolf until she had been killed. Having followed her tracks over the snow for 40 miles to the banks of the Connecticut, and then back again to Pomfret, they discovered her den, and spent the whole day in fruitless efforts to suffocate the enemy with burning sulphur, straw, and brushwood. The dogs were repeatedly sent into the cave, and returned wounded and dismayed. Putnam now declared his purpose of destroying the beast at whatever cost. The entrance to the cavern was about 3 feet wide and 2 feet high, and the passage continued of about the same dimensions for 30 or 40 feet. Providing himself with a torch of birch bark, and stripping off his coat and vest, Putnam next fastened a rope about his legs, in order that he might be drawn out at a given signal, and crept slowly in until he discovered at the further extremity the glaring eyes of the wolf, whose growls had been heard for some time. Having made a thorough survey of the situation, he gave the signal to his friends, who drew him forth with such celerity that the few clothes he had on were torn to rags and his skin severely lacerated. He then loaded his musket with 9 buckshot, and with torch and gun reëntered the den, and adjusted himself for the onset of the animal, which, howling, rolling her eyes, and lashing her tail, lowered her head to spring. At this instant, aiming at the eyes of the wolf, he fired, and was instantly drawn out, stunned by the shock and half suffocated by the smoke. After an interval of rest he loaded again, entered for the third time, and seeing the wolf prostrate on the floor of the cave applied the torch to her nose. Perceiving that she was dead, he seized her by the ears, again gave the signal, and the hero and the victim were drawn forth together. This adventure took place when Putnam was 25 years old. The 12 following years were spent in the pursuit of his calling, and with such success that when he entered the military service he was enabled to leave his family well provided for in case of his death. In 1755 he was appointed by the legislature a captain in Col. Lyman's regiment, and formed a strong company from among his neighbors, who were employed chiefly on special service as rangers. His first expedition was under Sir William Johnson against Crown Point. In 1756 he

s reappointed under his old commander Ly-
o, and in 1757 the legislature of Connecticut
ve him the commission of major. Perhaps
e most important service rendered by him
ring that year was the saving of the powder
agazine of Fort Edward at the conflagration
the barracks. For an hour and a half he
ntended with the fire until it was conquered,
many weeks of suffering elapsed before he
covered from the injuries he received. In
58, to escape from a strong party of Indians,
was obliged with a few men to descend the
ls of the Hudson at Fort Miller in a bateau.
e savages with admiration beheld him un-
rmed by their balls steering his boat down
pids never before passed, and conceived him
be an especial favorite of the Great Spirit.
e same year, when returning to Fort Ed-
ard from an expedition to watch the enemy
the neighborhood of Ticonderoga, his corps
s surprised by a party of French and Indians,
d he himself captured and bound to a tree.
hile in this situation a battle between his
n party and the enemy raged around him
r an hour. The tree against which he was
ced was part of the time in the hottest fire.
French officer, passing by, struck him in the
w with the butt of his gun. An Indian
mused himself for some time hurling his toma-
wk into the trunk of the tree to satisfy him-
f how near he could come to the prisoner's
dy and yet miss it. At length the party of
ench and Indians were forced to retreat, but
rried with them their captive, whom the
vages determined to roast alive. He was
d to a tree, and the fire was already blazing
riously, when his life was saved by the inter-
ntion of the French commander, Molang.
e next day he was taken to Ticonderoga and
terward to Montreal, where among other
isoners he met Col. Peter Schuyler, through
hose intervention he was treated according
his military rank and suffered to be ex-
anged. In 1759, having meanwhile been
ised to the position of lieutenant-colonel, he
rved under Gen. Amherst. In 1762 he com-
anded a Connecticut regiment in the expedi-
on against Havana, which was successful in
e object designed, though large numbers of
oops were destroyed by the climate. In
64 Putnam, who had now received a com-
ission as colonel, at the head of 400 Connec-
ut men accompanied Col. Bradstreet to De-
oit in the Pontiac war. The Indians however
tired without a battle, and a treaty was made.
or some years afterward he kept an inn at
ooklyn, the capital of Windham county, and
ring the same period frequently represented
e town in the legislature. In 1773 he was
gaged in the expedition that went up the
ssissippi to survey a tract above Natchez
r settlement, but Putnam himself never de-
ved any advantage of consequence from the
dertaking. The revolutionary war was now
ening, and Putnam from the beginning em-
aced zealously the cause of the colonists. In
April, 1775, at the alarm occasioned by the battle of Lexington, he left his plough in the field, turned loose the oxen, and mounting his horse rode to Boston in one day, a distance of 65 miles. Learning that the British had retreated and were besieged in Boston by the gathering hosts of militia, he went to Hartford to meet with the legislature, of which he was a member. By that body he was elected brigadier-general, and returning home he promptly gathered and organized a regiment, and after drilling them for some days marched with his men to Cambridge. Arriving there, he was soon sought after by the British officers, who offered him a commission as major-general in the royal service and a large pecuniary compensation, both of which he indignantly rejected. In May, 1775, he led a battalion of 300 men to Noddle's island, now East Boston, and succeeded in burning a British schooner, capturing a sloop, killing and wounding 70 of the enemy, and bringing off several hundred sheep and neat cattle. It was in great measure through his wish to bring on a general engagement, while the spirit of the troops was high, that the determination was taken to fortify Bunker hill. In the battle known by that name he acted a conspicuous part. When Washington arrived at the camp to take command in July, 1775, he brought with him commissions from congress for four major-generals, one of whom was Putnam; and to him alone did he deliver his commission, the others being withheld on account of the general dissatisfaction attending these appointments. In March, 1776, Washington being about to take possession of Dorchester heights, Putnam was ordered to attack Boston with 4,000 men in case the enemy should attempt to dislodge the Americans. Soon after the evacuation of that city he was ordered to take command in New York. He participated in the disastrous battle of Long Island, Aug. 27, 1776, and afterward went to Philadelphia to prepare for the defence of that place against an expected attack. After completing the necessary fortifications, he was stationed at Crosswick and subsequently at Princeton, where he remained until May, 1777. In that month he was ordered to take command in the highlands of New York. While there he sent back the following famous reply to Sir Henry Clinton, who claimed a lieutenant of a tory regiment as an officer in the British service: "Edmund Palmer, an officer in the enemy's service, was taken as a spy lurking within our lines; he has been tried as a spy, condemned as a spy, and shall be executed as a spy, and the flag is ordered to depart immediately. Israel Putnam. P. S. He has been accordingly executed." In the summer of this year the British troops surprised and took Forts Montgomery and Clinton, and obliged Putnam to retire to Fishkill. Subsequently he was removed from his command in the highlands, as Washington says, "on account of the prejudices of the people," and the dissatisfaction of

Hamilton and other officers, and also from the fact that a court of inquiry had been ordered to investigate the causes of the loss of Forts Montgomery and Clinton. This court decided unanimously that no blame could be attributed to Putnam, who not long afterward was stationed in Connecticut. In March, 1779, a corps of 1,500 British troops under command of Tryon made an incursion into that state, and approached Horseneck, one of Putnam's outposts. To oppose him were 150 men with two pieces of artillery, and with these Putnam took his position on the brow of a steep hill. After exchanging shots, as he saw the enemy's dragoons were about to charge, he ordered his men to retire to a swamp inaccessible to cavalry. He himself was hotly pursued, and finding that the dragoons were gaining upon him, he rode down a steep declivity, receiving on his passage a ball through his hat. Riding on to Stamford, he called out the militia, and effecting a junction with his little party he hung upon the rear of Tryon in his retreat and took about 50 prisoners, whom he treated with a humanity customary on his part, but so unexpected that the British general sent him a letter of thanks. During the summer of 1779 Putnam held command of the Maryland, Pennsylvania, and Virginia troops in the highlands of New York, and, assisted by his cousin Rufus Putnam and others, completed the fortifications at West Point. This was his last campaign. After the army went into winter quarters he returned home, and on setting out again for camp was attacked on his way by paralysis of his left side. He then took up his residence on his farm in Brooklyn, and there remained until his death. He was of medium height, of great physical strength, and his personal daring was of the most marked character. "He dared to lead where any dared to follow," is the inscription upon his tombstone.

PUTNAM, Rufus, one of the pioneer settlers of the state of Ohio, born in Sutton, Mass., April 9, 1738, died in Marietta, O., May 1, 1824. At the age of 16 he was apprenticed to a millwright, but by his own unaided efforts he managed to acquire some education. In 1757 he enlisted as a private soldier in the war against the French, and with occasional intervals was in active service until the close of 1760, in the beginning of which year he was made ensign. The following years he spent in farming and building mills, with the exception of about 8 months in 1773, when he went on an exploring expedition to the newly created government of West Florida. In 1775 he entered the continental army as lieutenant-colonel, was employed chiefly in the engineer department, and in 1776 was appointed by congress engineer with the rank of colonel. In 1777 he resigned his position as engineer, becoming colonel of a regiment in the Massachusetts line; in 1778 superintended the construction of the fortifications at West Point; and in Jan. 1783 received a commission as brigadier-general. In 1782 he had bought and removed his family to fiscated estate of Col. Murray in Rutla there lived for some years, serving as of the legislature and engaged in supe ing surveys ordered by the state of Ma setts and by congress. Early in 17 junction with Benjamin Tupper, he p a notice to the officers and soldiers of war, that from personal inspection he w isfied that the land in the Ohio country a much better quality than that of N land, and that with others he had dete to form a settlement there, and invited wished to do the same in the several of Massachusetts to send delegates to B A convention accordingly met in that March 1, over which Putnam presided, a Ohio company was formed. At a sub meeting 3 directors, of whom he was one appointed to make application to congress private purchase of lands, and the com procured from that body 1,500,000 acres rate of 66⅔ cts. an acre, although in they became possessed of somewhat le 1,000,000. A city was projected in th at the confluence of the Muskingum an rivers, and Putnam was intrusted with perintendence of the survey. On April he landed at the mouth of the Muskingu laid out the city of Marietta, the first nent settlement made in Ohio. From th he took an active interest in every thing lated to strengthen the infant colony a velop the resources of the country. On 9, 1788, he presided over the first court o eral quarter sessions which sat in that On March 31, 1790, he was made a ju and over the territory of the United Sta W. of the Ohio, and in 1796 was app surveyor-general of United States lands held the office until removed by Jeffers 1803. In May, 1792, he was also creat brigadier-general in the U. S. army, and commissioned to make a treaty with the tribes on the Wabash river. The foll year he resigned his commission in the as his health did not permit him to enga active service. In 1803 he was elected a ber from Washington county of the conv which on Nov. 29 of that year formed the constitution at Chillicothe.

PUTREFACTION (Lat. *putreo*, to be rot and *facio*, to make), the spontaneous deco sition of nitrogenous bodies, accompanied the evolution of fetid gases. The process sometimes treated as a variety of fermenta and called the putrefactive fermentation; it differs from fermentation, as ordinarily un stood, in commencing and continuing wi the addition of any other substance alread a state of decomposition. Putrefiable sub ces, when used to induce in other bodies change taking place in themselves, are term ferments. Putrefaction is either limited those organic substances which contain ni gen, or, if it occurs in others, is unattended ose noxious exhalations which most strikingly characterize the process. Vegetable sub- ances which contain much nitrogen, as the uciform plants, are subject to this change, but nimal matters of an albuminous character dis- lay its phenomena in the most marked degree. lesh, blood, milk, cheese, and wheaten flour the moist condition of dough and bread, hen exposed to an atmosphere moderately arm and damp, soon begin to experience a ovement in the molecules of their elements, nd new combinations of great variety are pro- uced, both liquid and gaseous. The active gent in this movement is the oxygen of the ir. It seizes upon some of the elements of he unstable compounds, and, breaking up the rrangements in which they were loosely held, ives rise to a multitude of new mixtures, some f them of extremely evanescent character, xisting only as stages in the progress of the lements back from their complicated organic ombinations to the simpler and more perma- ent inorganic compounds. The most conspic- uous among these products are the noisome aseous compounds of sulphur, hydrogen, phos- horus, ammonia, and carbon; carbonic acid lso is largely produced, and a variety of or- anic acids. Beside these are principles not ecognizable by their chemical reactions, but hose presence is made known by their terri- ly virulent effects upon the human system. uch are the poisons developed in animal bod- s within a few hours after death induced by isease, and retained within the tissues and uids during the continuance of putrefaction. he effluvia are also often extremely noxious nd infectious, but for the most part their effects re easily neutralized by chlorine or other dis- nfectants. The process of putrefaction may e checked in various ways, as by perfect ex- lusion of oxygen or air. The presence of wa- er or moisture being essential to it, the rapid emoval of this either by heat or absorption revents its initiation or continuance. At a emperature as low as the freezing point the hemical changes cease to take place, the ingre- ients remain unaltered for any length of time, nd when by the rise of temperature they are gain set free, putrefaction may ensue. The emperature of boiling water arrests putrefac- ion by coagulating the albumen; and at still ower degrees, even to 100° F., it is doubtful whether the true putrefactive process goes on. A great variety of antiseptics or antiputrefac- ive compounds are employed to arrest decay, ome of which, as salt, sugar, alcohol, &c., derive their efficacy chiefly from their property of absorbing moisture, and others from their forming with the organic ingredients combinations of a more stable character. This branch of the subject is further treated in the articles Antiseptics and Preservation of Food.

PUTTY, a composition of whiting and linseed oil worked by hand into a doughy mass, and then beaten with a mallet until it becomes of uniform consistency. It is used by glaziers to secure panes of glass in the sashes, and by carpenters for stopping holes in their work.

PUTTY POWDER, a preparation of the oxides of tin and lead used for polishing glass, mineral, and metallic surfaces. The best kinds contain the least oxide of lead; the poorest consist of this chiefly, and are prepared by the process described in the article Litharge. The lumps of oxide obtained are ground to powder and sifted. They are of various colors. That preferred by opticians and marble workers is a heavy white powder; it is the smoothest and at the same time the most cutting. A pure oxide of tin, superior to any other sort of polishing putty, is prepared by dissolving metallic tin in diluted *aqua regia*, and after filtering causing the oxide to be precipitated by ammonia. It is then collected, washed with water, and pressed dry in a cloth filter. The mass is broken up, dried in the air, levigated on a glass plate, and then heated in a crucible to a low white heat. The fine particles thus assume crystalline forms with cutting edges.

PUY, Le (anc. *Anicium Vellavorum*), a town of France, capital of the department of Haute-Loire, 270 m. S. S. E. from Paris; pop. in 1856, 14,428. It is one of the most picturesque towns of France, being situated at the junction of the valleys of the Loire, Borne, and Dolaison, and built in the form of an amphitheatre upon the steep southern acclivity of Mont Anis, which is crowned by a mass of volcanic rock with a flat top, called Rocher de Corneille. The Borne is crossed by a bridge, near which is the Rocher de St. Michel, a remarkable conical rock rising to the height of 265 feet above the stream. The Rocher de Corneille has on its summit a colossal statue of the Virgin, cast from cannon captured at Sebastopol in 1855, and the Rocher de St. Michel an old chapel in the Romanesque style. The principal part of the town occupies a series of terraces upon which the houses rise one above another, and the streets in many places are impracticable for wheeled conveyances. The cathedral is a Gothic structure of the 10th century, standing in a very conspicuous situation, and reached by a stairway of 118 steps. The manufactures consist of lace, woollen goods, leather, and nails; and there are also fulling mills, dye works, and a bell foundery. It is a place of great antiquity, and during the middle ages several ecclesiastical councils were held in it.

PUY-DE-DOME, a S. E. department of France, in the old province of Auvergne, bounded N. by the department of Allier, E. by Loire, S. by Haute-Loire and Cantal, and W. by Corrèze and Creuse; area, 3,070 sq. m.; pop. in 1856, 590,062. It is divided into 5 arrondissements, and Clermont is the capital. With the exception of a small part of the S. W., which is drained by tributaries of the Garonne, the waters of the department flow to the Allier, which traverses it in a N. and S. direction and belongs to the valley of the Loire. The surface consists of an undulating basin, called the valley of Limagne, with a general inclination toward the N. The mountains of Forez, an offset of the Cévennes, bound the valley on the E., and are covered with pine forests interspersed with some poor pastures, and a few patches of oats and rye. The W. limit is formed by a portion of the Auvergne mountains, here divided into two principal groups, that to the N. being known as the Monts Dômes and that in the opposite direction as the Monts Dores. The most elevated point in the first of these groups is Puy-de-Dôme, from which the department takes its name, and of the last Puy-de-Sancy, the highest mountain in the interior of France, which are respectively 4,846 and 6,225 feet above the sea. These mountains are all of volcanic origin, and many of the extinct craters and the course of the lava which flowed from them are plainly visible. Mineral springs are numerous, and traces of many metals are found, but the only mines worked are lead, antimony, and coal. The soil of the Limagne is fertile; the hillsides are covered with orchards and vineyards; there are extensive chestnut plantations, and the forests contain pine, oak, and beech. The manufactures of the department are not very important. Puy-de-Dôme forms the see of the bishop of Clermont, has numerous schools, and returns 6 members to the legislative chamber of the empire.

PYAT, Félix, a French journalist, dramatist, and politician, born in Vierzon, department of Cher, Oct. 4, 1810. He studied law in Paris, and was admitted to the bar in 1831, but gave up his profession to devote himself entirely to literature and politics. He contributed to *Figaro*, the *Charivari*, the *Revue de Paris*, *Artiste*, *Livre des cent-et-un*, *Paris révolutionnaire*, and *Salmigondis;* furnished Jules Janin with one of the most striking chapters of his *Barnave;* and was connected as *feuilletoniste* with the *Siècle*, and afterward for several years as political editor with the *National*. His first play, which he composed in conjunction with his friend Théodore Burette, *Une révolution d'autrefois*, was brought out at the Odeon, March 1, 1832, but was suppressed at once on account of its bold political allusions. *Une conjuration d'autrefois*, printed in 1833 in the *Revue des deux mondes*, and *Arabella*, in which, under assumed names, he branded the supposed accomplices in the death of the duke of Bourbon, were of a similar political character. In conjunction with Luchet, he produced in 1834 *Le brigand et le philosophe*, and in 1835 *Ango*. Politics now engaged his attention for about 6 years. Returning to the drama in 1841, his *Deux serruriers* had an extraordinary run; and his *Cedric le Norvégien* (1842), *Diogène* (1846), and *Le chiffonnier* (1847), his last play, were also successful. In 1844, for a violent pamphlet, *Marie Joseph Chénier et le prince des critiques*, against his former friend Jules Janin, he was sentenced to 6 months' imprisonment. He left the *National* for the more revolutionary *Réforme*, and on the proclamation of the republic in 1848 sided with the soc Elected to the constituent assembly, h came one of its secretaries, and voted w party of the mountain. After his re in 1849, he signed Ledru-Rollin's "Ap Arms," June 13, accompanied him to th *servatoire des arts et métiers*, and mak escape first took refuge in Switzerl then removed to Belgium, where he occ ally wrote political pamphlets in the f letters to the count de Chambord, Bar prince de Joinville, the president of the F republic, &c. He became connected w "European revolutionary committee," last pamphlet was an apology for the a to assassinate Napoleon III. He is one of who refused to profit by the amnesty g by the emperor in 1859.

PYGMALION, in Greek legendary hi a king of Cyprus, whom the licentious co of his countrywomen so disgusted that he ceived a hatred against the whole sex. cording to Ovid, he made an ivory f statue of such exceeding beauty that h desperately in love with it himself, and p to Venus to endow it with life. The g granted his request. Pygmalion then m the object of his affections, and by her son called Paphus, who founded the ci that name. Rousseau's musical play of *malion* is founded upon this legend.

PYLOS, the name of 3 towns of an Greece, one of which was situated in another in Triphylia, and the third and important in Messenia, on the promont Coryphasium. The last was probably the los spoken of in the poems of Homer as residence of Nestor. The earlier city on promontory was forsaken by the inhab after the close of the second Messenian and the promontory remained deserted the Peloponnesian war, when in 424 B. was taken possession of and fortified b Athenian general Demosthenes. It be memorable for the defeat of the Spartans long after, but at the close of the war p again into the hands of the Lacedæmon The modern city of Navarino is situated the site of the old town.

PYM, John, an English patriot and or born at Brymmore, Somersetshire, in 1584. in London, Dec. 8, 1643. He was of a family, and was educated at Pembroke col Oxford, but left without taking his degree. applied himself to the study of common la one of the inns of court. He became a c in the office of the exchequer, entered pa liament in 1614, and in 1620 became consp ous as a leader of the country party. In he was one of the 12 commissioners sen James I. at Newmarket in behalf of the p ileges of parliament, and at the close of year was sentenced with Coke, Philips, Mallory to imprisonment for his oppo to the measures of the court. In the first liament of Charles I. he was indefatigabl

support of the rights of the people, and in
26 was one of the managers of the articles
impeachment against the duke of Bucking-
m. In 1639 he held communications with
commissioners sent to London by the
otch Covenanters, and accompanied Hamp-
n through the country to incite the people
send in petitions. In the short parliament
1640 he was one of the most active mem-
rs, and in the long parliament exerted great
luence not only by his eloquence and knowl-
ge of common law, but by his zeal in re-
icting the royal authority. At the opening
the session he made a speech upon griev-
nces, as regarded the privileges of parliament,
ligion, and the liberty of the subject. On Nov.
he moved to impeach the earl of Strafford for
gh treason, and as one of the managers on
part of the house of commons he bore a
ominent part in the proceedings which led
the execution of that minister. In the sub-
quent trial of Laud he also made a violent
eech against the prisoner, and was the mover
the grand remonstrance, which enumerated
faults of the royal administration from the
ession of Charles. He was one of the 5
mbers of parliament whom the king attempt-
in person to seize; and after the departure
Charles from London, he assisted in carrying
the executive branch of the government.
t in 1643 he put forth a vindication of his
nduct in answer to the charges brought
inst him, from which it was thought doubt-
with which of the two parties then divid-
the kingdom he would go. In Nov. 1643,
was appointed lieutenant of the ordnance;
d dying not long after, he was buried in
stminster abbey "with wonderful pomp
d magnificence," 10 members of the house
commons carrying his bier. Pym was in re-
gious sentiment a strong Calvinist and zeal-
usly opposed to Arminianism. In consequence
his popularity and his influence he was nick-
med King Pym. "His parts," says Lord Clar-
don, "were rather acquired by industry than
pplied by nature or adorned by art; but beside
exact knowledge of the forms and orders
the house of commons, he had a very comely
d grave way of expressing himself, with great
ubility of words, natural and proper. He
derstood likewise the temper and affections
the kingdom as well as any man, and had
served the errors and mistakes in govern-
ent, and knew well how to make them ap-
ar greater than they were."

PYNAKER, Adam, a Dutch painter, born
Pynaker, between Delft and Schiedam, in
21, died in 1673. In his youth he resided
several years at Rome, where he acquired
ideal or pastoral style of landscape painting.
s pictures contain charming effects of sun-
ght, with clear, warm skies, and trees and
her natural objects are painted with a broad,
e pencil, and great richness of color. The
of his works are of cabinet size, and many
these are owned in England.

PYRAMID, in mathematics, a solid whose base is a plane figure of any number of sides, and whose other faces are plane triangles all terminating in a point above called the vertex. It is triangular, quadrangular, pentagonal, and so on, according as the figure of the base is triangular, quadrangular, pentagonal, &c. It is called right when, having for its base a regular polygon, a perpendicular from its vertex falls upon the centre of the polygon. It is called regular when it is bounded by 4 equal equilateral triangles, and is then known as a regular tetrahedron. The pyramid corresponds among plane solids to the cone among curve solids. As popularly understood, it is a solid whose base is a square and its faces isosceles triangles, or triangles having two equal sides.

PYRAMID, a structure in masonry, usually of a square base with sides meeting in a point at the top, much used among the earliest nations in different parts of the world, either as a sepulchral monument or for religious purposes. By reason of the simplicity of the figure such edifices were easily raised of the largest dimensions; and owing to their solidity, as well as the durability of the materials employed, they have stood longer than any other works of man. The most famous pyramids in the world are those of the ancient Egyptians, standing near the W. margin of the valley of the Nile, a few miles above Cairo, and found at short intervals usually in groups for some 60 or 70 m. further up the river, and not far back from it. As many as 60 have been counted, the ruins of many more are to be seen, and great numbers have without doubt disappeared in the long period of nearly 40 centuries since they were constructed. In the early Egyptian dynasties the capital, Memphis, stood about 10 m. above Cairo on the W. bank of the river. The burial places of the multitudes with which the valley was peopled were along the edge of the rocky tract known as the Libyan range, which intervenes between the cultivated lands of the Nile and the great desert, whose drifting sands now cover the region around the pyramids. In the rocks they excavated their tombs and built them up of the materials at hand, and over those designed for the king and probably other important personages they raised the pyramids, some of which from their vast size have ranked among the principal wonders of the world. From Cairo several groups are in full view. The nearest group is that of Ghizeh, consisting of three pyramids, two of which exceed all others in their dimensions. Beyond these are seen the three pyramids of Aboo Seer, then the great pyramid of Sakkarah, showing its construction in steps, and accompanied by several smaller pyramids. Some distance beyond these are discerned the two majestic pyramids of Dashoor, and others still appear yet further to the S. From the investigations which have been made to determine the character of these structures, it appears that they date from the period of the 3d dynasty to the

12th, after which the Egyptians ceased to build them. Each one was commenced over a sepulchral chamber excavated in the rock, and during the life of the king for whom it was intended the work of building up the structure over this chamber went on, a very narrow and low passage way being kept open as the courses of the stone were added, by which access from the outside was secured to the central chamber. At the death of the monarch the work ceased, and the last layers were then finished off and the passage way closed up. The piles were constructed of blocks of red or syenitic granite from the quarries of Asswan, and also of others of a hard calcareous stone from the quarries of Mokattam and Tourah. They were of extraordinary dimensions, and their transportation to the pyramids and adjustment in their proper places indicate a surprising degree of mechanical skill. Their thickness varied from more than 4 to less than 2 feet, and when arranged one upon another forming steps up the outer slopes, the thickness of the stones determined the height of these steps. Those near the top are of the thicker stones, but the blocks are of moderate length compared with those near the base. The foundations for the structures were excavated in the solid rock, sometimes to the depth of 10 feet, and upon this the great stones were arranged and built up layer upon layer, and one shell succeeding another, the spaces within being filled in with smaller stones closely packed. To quarry and move the immense blocks to the pyramids and then raise them to their places must have been a work calling in play no little engineering skill, notwithstanding an unlimited amount of human labor was at command. Near the summits however the number of men that could aid in raising the huge stones must have been comparatively small for want of room, and it seems that some mechanical power must have been employed beside any which we know they possessed. The probability of this is confirmed by the fact that cavities in the stones have been found, which appear as though they might have been worn by the foot of derricks turning in them. The 3 pyramids of the Memphis group stand upon a plateau about 137 feet above the level of the highest rise of the Nile, not far apart from each other, and nearly on a N. E. and S. W. line. Like the other pyramids of Egypt, their 4 sides are directed toward the cardinal points. The largest of them, known as the great pyramid, covers at present an area of between 12 and 13 acres, the side of its square measuring 746 ft.; and its height is 450 ft. 9 inches. Its dimensions have been reduced from a base of 764 ft. and a height of 480 ft. by the removal of the outer portions to furnish stone for the city of Cairo. Thus despoiled, the walls have lost their smooth finished surface, in which state they were left by their builders, who, commencing at the top, filled in with small stones the angles formed by the recession of each upper layer, and bevelled off the upper edges of the great blocks, till reaching th they left each side of an even surface s at an angle of 51° 50′. By stripping o outer casing the courses of stone appear form of steps, which, though ragged an equal, can be ascended even by ladies. great pyramid has 203 of these steps, th ones being 4 ft. 10 inches high. The hor surfaces were nicely finished, and the s were joined together with a cement o without sand. The structures are so nearly that the spaces occupied by the chamb passages are of little account in estimatin contents. Those of the great pyramid an to about 82,111,000 cubic feet of mason side about 7,000,000 more which have be moved, and the total weight of the st estimated at 6,316,000 tons. The only en is on the N. face, 49 ft. above the bas about 24 ft. E. of the central line. The m ry about it is much broken away, and the of broken stones reach up from the nearly to its level. A passage way, only 11 in. high and 3 ft. 5½ in. wide, leads f down a slope at an angle of 26° 41′ a dis of 320 ft. 10 in. to the original sepulchral ber, commonly known as the *subterr* apartment, and beyond this 52 ft. 9 in. in rock, with an area in this portion of only 7 in. in width and 2 ft. 8 in. in height. supposed that it was intended to excavat other chamber at the end of this passag that it was not done on account of the m continuing to live until it was found exp to close up the mouth of the passage wit external casing of masonry. The sep chamber is 46 ft. long by 27 ft. in widt its height is 11½ ft. The entrance passag ft. long, connects with a branch passage, w rises at an angle of 26° 18′, and thus ex 124 ft., when it becomes level and runs 1 further. This connects with several cham and passages, the position and nature of w cannot be described without the aid of illus ed plans. One of the former, situated ne in the central portion of the pyramid, and ft. above its base, is known as the qu chamber. This measures 17 ft. by 18 ft. 9 i and 20 ft. 8 in. high, and has a groined r It appears to have been intended for a sar agus; but the only one found was in wh called the grand or king's chamber. This is apartment lined with red granite highly p ished, single stones reaching from the floor the ceiling, and the ceiling is formed of 9 la slabs of polished granite, extending from w to wall. It is 34 ft. 3 in. long, 17 ft. 1 in. wi and 19 ft. 1 in. high. Over it are 5 sma chambers apparently built to shelter the larg room beneath from the weight of the masonry. The room is perfectly plain, and contains only a sarcophagus of red granite, which is 7½ ft. long, 3 ft. 3 in. wide, and 3 ft. 5 in. high, too large to have been introduced through the entrance passage, and must therefore have bee placed in the room when this was built. It is

pposed that it contained a wooden coffin with
mummy of the king, and that these long
ce disappeared when the pyramids were first
ened and plundered. In the construction of
e pyramids arrangements were made for
ooking up the important passages with huge
asses of granite, and the obstacles thus inter-
sed have greatly impeded their exploration,
d sometimes rendered it necessary to open
w passages past the obstructions. It is prob-
le that on account of these extraordinary pre-
utions there are yet undiscovered apartments
no little interest in the immense body of
ese structures. Notwithstanding they have
centuries been objects of great curiosity,
d have been visited, explored, and plundered
people of different nations, new apartments
ere discovered in 1835 by Col. Howard Vyse,
also hieroglyphics upon the stones, made by
quarrymen, and which when deciphered
oved to be the name and titles of the rul-
g monarch Shufu, the Cheops of Herodotus.
he second pyramid stands on a base 33 ft.
ove that of the great pyramid, and in an ex-
vation made for it in the rock. It measured
iginally 707 ft. 9 in. square, and 454 ft. 3 in.
gh; but these dimensions are now reduced
spectively to 690 ft. 9 in. and 447½ ft. The
gle of its slope is 52° 20′. The upper portion
its casing is still preserved, and persons can
cend this, though not without danger, espe-
lly if liable to become dizzy by losing sight
the lower portion of the structure. This
yramid has two entrances, one 37 ft. 9 in.
ove the base, and the other built out in front
the base, each leading by an inclined pas-
ge of about 100 feet in length to the same
pulchral chamber. This has a roof of the
ape of the pyramid itself, and measures 46
2 in. by 16 ft. 2 in., and is 19 ft. 3 in. high.
contains a granite sarcophagus 6 ft. 7 in.
ng, 3½ ft. wide, and 2 ft. high. It was
ached with great difficulty by Belzoni in
818, who found a Cufic inscription recording
he visit of the caliph Othman and the open-
g by him of the pyramid, A. D. 1196-'7.
he only remains met with were those of a
ll. The third pyramid is only 354½ ft. square
nd 203 ft. high. It was explored in 1837 by
l. Vyse, who discovered several apartments,
one of which were a highly finished sar-
ophagus, a mummy case, bearing the name
King Menkaré, and the body of a workman.
he last two are now in the British museum,
t the sarcophagus was lost on the passage.
his pyramid, though the smallest, is the best
onstructed of the three, and indeed the style
the work is more costly than that of any of
e other pyramids of Egypt. In the same
cinity are 9 smaller pyramids, supposed to
ave been the tombs of some of the relatives
the kings who constructed the larger pyra-
ids, and an immense number of tombs, some
uilt up above the surface, some excavated in
e rock, and some subterranean channels. Near
e great pyramids is also the famous sphinx,
a figure of a recumbent lion with the head of a man fashioned out of a projecting rocky ledge, 188 ft. 9 in. long. Some defective portions, as also the legs, are made up by masonry. In front are steps leading up to the sanctuary and tablets; but the drifting sands of the desert keep these mostly concealed. Of the other pyramids further S., the largest are of the Dashoor group, of which there are 5, 2 of stone and 3 of rough brick. One of the former is now reduced from 719½ to 700 ft. square, and from 342½ to 326½ ft. high, and the other is 616½ ft. square and 319½ ft. high.—The pyramids were described very particularly by Herodotus, to whom they were of great interest for their antiquity even in his time, and also as the most wonderful monuments of human labor. He states that the great pyramid was built by Cheops, who stopped all other works connected with religious rites, and compelled his people to the number of 100,000 at a time to labor in this undertaking, and at the end of 3 months their places were supplied by the same number of fresh hands. To facilitate the transportation of the stone from the Tourah quarries, a causeway was built 3,000 ft. long, 60 ft. wide, and 48 ft. high, which required 10 years for its completion. The subterranean chamber was in an artificial island formed by a canal brought up from the Nile. This seems improbable, considering the elevation of the ground, about 140 ft. above the highest rise of the river. The construction of the pyramid required, according to Herodotus, a further period of 20 years, and he describes the method of building by steps and raising the stones from layer to layer by machines, and finally of facing the external portion from the top down. Diodorus calls this monarch Chemmes or Chabryes, and Manetho and Eratosthenes call the builder of this pyramid Suphis or Saophis I. Pliny makes mention of the great pyramid and of persons ascending it in his day, though at that time the casing had not been removed. The builder of the 2d pyramid is said by Herodotus and Diodorus Siculus to have been the brother and successor of Cheops and named Cephren. The builder of the 3d pyramid was King Menkaré, variously given by different writers, the 3d king of the 4th dynasty. The date of these structures is thus not far from 2,500 B. C. When they were first explored in more recent times is not known; but it is suggested that they were rifled by Cambyses, who is spoken of by Herodotus (iii. 27) as having opened ancient sepulchres at Memphis. They were visited and described by Belminus, A. D. 1053; and more recently by numerous travellers, as Belzoni, Denon, the expedition accompanying the army of Napoleon, Salt, Caviglia, and Col. Howard Vyse, who spent a fortune in their exploration, aided by Perring. Many of the works in which they are described are referred to at the close of the article EGYPT, to which may be added as particularly relating to this sub-

ject Vyse's "Operations carried on at Ghizeh in 1837" (3 vols. 8vo., London, 1837 *et seq.*)—Pyramids are frequently met with in the upper part of the valley of the Nile. There are many in Nubia about lat. 17° and 18° N., the sepulchres of the monarchs of Meroë and of Ethiopia; a single group N. of Gebel Barkal comprises no fewer than 120. Others are met with in other ancient countries of the East. At Birs Nimroud is the step-shaped pyramid built by Nebuchadnezzar of bricks of different colors, known as the temple of seven spheres, for an account of which see BELUS, TEMPLE OF. This was 235 ft. high with a perimeter of 2,286 ft. The same monarch built the pyramidal brick structure of Mujellibe at Babylon, the ruins of which still remain. At Benares in India are also the ruins of pyramids; and others were built in ancient times at Peking, and again at Suka in Java. At Rome one was constructed 20 or 30 years B. C., in honor of C. Certius; an imitation of the Egyptian monuments, and furnished with a sepulchral chamber. It is 120 ft. high on a base of 95 ft. diameter, built of hewn stone and marble-faced.—In Mexico are similar structures far exceeding in the area they cover the dimensions even of the great pyramid of Egypt. The principal one of these is described in the article CHOLULA. The two pyramids of Teotihuacan, in the same country, are situated in the centre of the plain of Otumba, 7 leagues N. E. of the city of Mexico, and called respectively *tonatiuh itzaqual*, and *metzli itzaqual*, or "houses of the sun and moon." The first named is of 4 stages, 680 ft. square at its base, 221 ft. in vertical height, with a level area at its summit, where was anciently a great statue of the sun. The house of the moon is 144 ft. high, with relatively small base, but with the same number of stages. They seem to have been built of sun-dried bricks, faced with stone, and finally covered with a layer several inches thick of a close and hard cement. The lesser pyramid contains a number of chambers, reached by an adit which enters on the S. side between the 2d and 3d terraces, and descends at an angle of 30°, almost precisely as in the case of the great Egyptian pyramid of Ghizeh. The sides of these pyramids coincide with the cardinal points. A great number of smaller pyramidal structures or mounds are scattered over the plain around them, some of which are ranged in squares, and others in parallel lines, constituting what the Mexicans called *micoatl* or "path of the dead." It has been conjectured from this name, that this was a general burial place of the distinguished dead among the people who built the great pyramids. Boturini, however, conjectures that as the larger structures were dedicated to the sun and moon, the smaller ones were dedicated to the planets and stars. Near the base of the pyramid of the sun lies a great sculptured stone, 10 ft. 6 in. in length by 5 ft. broad, which it is supposed once crowned the pyramid. Clavigero says that two idols of great bulk, carved of stone, and covered with gold, surmounted both structures; and that the breast of the idol of the sun was hollowed out so as to contain a massive image of the planet in solid gold. He adds that the conquerors immediately possessed themselves of the gold, and that the idol was destroyed by order of the bishop of Mexico.

PYRAMUS AND THISBE, a youth and maiden of Babylon, whose love and fate are celebrated by Ovid in the *Metamorphoses*. Their parents opposed their union, but the lovers, living in adjoining houses, found means to converse with each other through a hole in the wall, and once made an agreement to meet at the tomb of Ninus. There Thisbe arrived first, but, terrified by a lioness which had just torn to pieces an ox, she hid herself in a cave, and in her flight lost her mantle, which was rent by the lioness and soiled with blood. When Pyramus came and found the garment torn and bloody, he imagined that Thisbe had been killed, and thereupon fell upon his sword. When Thisbe returned and found the body of her lover, she slew herself with the same sword. This tragedy was enacted under a mulberry tree, the fruit of which, before white, has ever since been of the color of blood.

PYRÉNÉES, the chain of mountains which separates France from Spain, commencing on the Mediterranean at Cape Creux and running out to the S. E. extremity of the bay of Biscay. Under the name of the Cantabrian mountains, the same chain continues near the N. border of Spain and Portugal to the Atlantic ocean at Cape Finisterre. The distance from the Mediterranean to the bay of Biscay is 270 m. The breadth of the mountain range is from 20 to 60 m., the narrowest portion being near the Mediterranean, and here it is crossed by the carriage road through Figueras. At the W. extremity the pass is through the town of Irun. The mountains consist of a few parallel main ridges, with numerous spurs and transverse elevations, the chain being unbroken throughout its length by the passage of any river across its line. The mountains attain their greatest height and breadth near the central portion of the range. On the S. side the transverse valleys extend down between the tributaries of the Ebro, which stream, rising near the W. extremity of the chain, receives nearly all the waters whose source is on the S. side of the mountains and discharges them into the Mediterranean. These valleys, traced toward their head, sometimes terminate in long depressions reaching far into the axis of the main ridge, the height of which is thus so reduced that the gaps or breaks, called *cols* (necks) and *portes* (gates), serve for passes, rarely however fitted for carriage roads. Sometimes the valleys terminate abruptly in the heart of the mountain, where they are bounded by precipitous walls that rise to great heights. The circular basins thus formed are designated *cirques* or *oules*. The height of the chain is remarkably uniform for long distances. Toward the extremities it falls away, but in the interior much of it exceeds 8,000 or 9,000 feet, within which is the line of perpetual snow. The highest peak is Néthou, 11,068 feet above the sea; after this Mont Perdu, 10,891 feet; Le Cylindre, 10,790; Maladetta, 10,764; Vignemale, 10,716; Montcalm, 10,663; Pic du Midi, 9,350; and many others above 9,000 feet. The mean elevation of the summit line is estimated at 7,990 feet. On the N. side glaciers are occasionally met with upon the highest slopes, but they do not fill up the deep valleys as do those of the Alps. The geological formations are the metamorphic granites and slates, granular limestones, &c. They give a rugged aspect to the higher portions, which, seen from the plains on the French side, appear notched and serrated, whence the term *sierra* applied to such forms. On the Spanish side the same formations are exposed in the deep precipitous cross valleys. Among the mineral products of these rock formations are ores of several of the metals, none of which however have proved of much importance except those of iron. From remote times they have been actively worked, and the most economical method of producing wrought iron direct from the ore was first practised in this region in the furnace still known as the Catalan forge. Beside these products the mountains have afforded large supplies of timber of excellent qualities for ship building. The forests are still extensive, and serve as haunts for bears, wolves, wild boars, foxes, wild goats, and other animals. On the French side are numerous mineral springs, hot and cold, some of which are famous watering places, known as *bagnères*. On this side the pasturage is most excellent and extensive, and on the smoother lands near the base of the mountains are fine orchards and vineyards. On the other side the hardier races are engaged in other occupations, among which smuggling is almost universal. Beside the main passes which connect France with Spain near the Mediterranean and the bay of Biscay, there are several secondary passes not so easily accessible, particularly with carriages. The chief of these are the Puerto de Maya and the Puerto de Roncesvalles in Navarre; those of Canfranc, Panticosa, Gavarnie, Vielsa, Brèche de Roland, and Marcandau in Aragon; and of Plan de Aose, Puigcerda, and Col de Pertus in Catalonia.—The inhabitants of the Pyrénées comprise a variety of people belonging to originally distinct races, several of which yet maintain striking characteristics. On the W. part of the range are the Basques, descendants of the ancient Cantabrians, still retaining the dress and manners of antiquity, and speaking a peculiar language. (See Basques.) The Aragonese are also a peculiar and hardy race, reputed for their obstinacy of character. But on the N. side the French possess the more ardent and volatile disposition belonging to their nation. From early periods of history the Pyrénées have been the scene of interesting military events. Among these are the passage of Hannibal and afterward of Cæsar by the Col de Pertus, and the defeat of Charlemagne in 778 by the Basques near the pass of Roncesvalles, toward the W. extremity of the range. By the same pass the Black Prince invaded Navarre with an English army, and Wellington in 1813 drove the French back into their own country.

PYRÉNÉES, Basses. See Basses-Pyrénées.

PYRÉNÉES, Hautes. See Hautes-Pyrénées.

PYRÉNÉES-ORIENTALES, a S. department of France, comprising the old province of Roussillon, bounded N. by Aude, E. by the Mediterranean sea, S. by Spain, and W. by Ariége; area, 1,571 sq. m.; pop. in 1856, 183,056. Capital, Perpignan. A wide plain stretches along the shore of the Mediterranean, and the Pyrénées, which extend along the S. and W. boundary, have 3 offsets that traverse the department in a general E. and W. direction, forming valleys that are drained by the Agly, the Tet, and the Tech, all of which flow into the Mediterranean, but none of them are navigable. The Aude rises in the E. part of Pyrénées-Orientales and flows N. Mines of coal, sulphur, and alabaster are worked. Iron ore is abundant and is extensively smelted. No part of the soil is very fertile, but the plain bordering the sea is extensively irrigated, and produces luxuriant crops of grass, grain, and vegetables. The vine and olive thrive well in the W. part of the department, and nearly 9,000,000 gallons of wine are annually produced. The principal manufactures are broadcloth, hosiery, moleskins, leather, iron, tin, and pottery.

PYRITES (Gr. πῦρ, fire), an ancient name of certain stones which gave fire when struck by steel; applied by Pliny to millstones, and by others to various minerals, as flint and the bisulphurets of iron and of copper. Dioscorides describes pyrites as a species of stone from which copper is melted. The term is now applied to a variety of native metallic sulphurets, such especially as have a decided metallic lustre; and particularly to the yellow bisulphuret of iron and that of copper. (See Copper, and Iron.) Iron pyrites is a very common mineral, of golden appearance, and is frequently mistaken by those unacquainted with minerals for the precious metal. Its sulphurous character is easily shown by the odor given out when the mineral is crushed and thrown upon a red-hot shovel. Its composition is: sulphur 53.3, iron 46.7. Being often met with in large veins and obtained in abundance in working other ores, of which it serves as a gangue, it is profitably employed for the production of sulphur.

PYROLIGNEOUS ACID (Gr. *πῦρ*, fire, and Lat. *lignum*, wood), also called pyroligneous and wood vinegar, the compound mixture of the volatile products from the destructive distillation of woody matters, and which when purified yield acetic acid, wood naphtha, creosote, tar, &c. The method of producing it is noticed in the article Acetic Acid, vol. i. p. 67, as also its use in the crude state for furnishing compounds useful as mordants in calico print works, as pyrolignate of iron, alumina, &c. It has also been applied to various other uses, as for example, in medicine as an antiseptic and stimulant in a wash for gangrene and ulcers; and its antiseptic qualities have led to its use in preserving articles of food, as herrings and other fish. The process is an auxiliary one to drying in the shade, which precedes the dipping of the articles in the acid. Herrings first cured by a sprinkling of salt left upon them for 6 hours, and then drained, being immersed a few seconds in pyroligneous acid and then dried for two months, are in an excellent condition for preservation and retain a smoky flavor. The addition of a quart of the acid to the common pickle for a barrel of hams will cause the hams to acquire this flavor as if they had been smoked in the ordinary way.

PYROLUSITE. See MANGANESE.

PYROMETER (Gr. πυρ, fire, and μετρον, measure), a thermometer for measuring degrees of temperature above the range of ordinary thermometers, appropriate for indicating the heat of furnaces, the melting point of metals and alloys, &c. The principle upon which most of the various forms of the instrument are based is the expansion of metals by heat, which, for want of any other standard of comparison, is assumed to increase proportionally with the increase of temperature. Musschenbroek, who was the first to construct a pyrometer, and introduced the name about the year 1730, employed a metallic bar fixed at one end, and connected at the other with wheel work which multiplied the movement caused by the expansion of the bar, as this was heated. This was improved by other physicists at subsequent times, their attention being especially directed to the mechanism by which the motion was communicated through wheel work and levers to the index. The principle of this instrument is still retained in the most perfect pyrometer now known, which is that of Professor Daniell, first described in the "Philosophical Transactions" for 1830, and a modification of a similar instrument previously used by Guyton-Morveau. The rod of platinum or of iron is dropped into a longitudinal cavity bored nearly through a bar of thoroughly baked black lead, and rests upon the solid portion at the bottom. A short cylindrical piece of porcelain (called the index) is set on the top of the platinum rod, and projects a little above the top of the black lead bar, to which it is bound by a strap of platinum, the front half of the rod at the top being cut away, so as to leave the porcelain rod partially exposed, and present a shoulder for the adjustment of the scale by which the exact position of the porcelain bar is measured before and after the heating of the apparatus. The index portion of this scale is constructed somewhat like a pair of proportional dividers, and one of the short arms being brought to the same point on the porcelain rods at the two observations, the long arm marks by a vernier upon a graduated arc attached to the extremity of the other long arm 10 times the change in length which the rod has undergone. The degrees on the scale being made with reference to the mercurial scale of the thermometer, the amount of heat to which the rod has been exposed may be immediately expressed in degrees of Fahrenheit. In the construction of the scale, several ingenious contrivances are introduced to increase its delicacy, which cannot be intelligibly explained without drawings. This part of the instrument not being exposed to the fire, its indications must be more accurate than those of other pyrometers, all portions of which are more or less heated in the trials. M. Brongniart employed in 1805 a pyrometer of somewhat similar character to Prof. Daniell's for indicating the comparative heat of the porcelain ovens, and thus the exact time for arresting this in the process of vitrifying the ware in coloring. The heat employed not exceeding the fusing point of silver, this metal was found for several reasons to be the best for the pyrometer. A bar about 8 inches long was inserted in a groove of porcelain, and the free end was made to press against a porcelain rod which moved a needle upon a graduated arc 10 times the distance traversed by the rod. The instrument was not regarded by Brongniart as a correct measurer of degrees of temperature, but only of the difference between the dilatation of a bar of silver and that of a bar of hard porcelain of the same length. The latter element, though small, still amounts to a certain unknown quantity.—A pyrometer was invented by Wedgwood, and described in the "Philosophical Transactions" for 1782, 1784, and 1786, of which much use was made for determining the fusing points of metals; and for a long time these were regarded as established by its very erroneous indications. On this account it is worthy of notice, though it is no longer used. Wedgwood assumed that clay, formed into cylinders, contracted in its dimensions in proportion to the degree of heat to which they were exposed; and his pyrometer consisted of such cylinders with a gauge for measuring their exact length. The principle was proved to be defective, not only from the variable qualities of the clays, and the different methods (as regards pressure especially) of forming the cylinders, but most decisively from the fact that a long continued moderate degree of heat produced as great an amount of shrinkage as a higher degree of shorter continuance.—Owing to the uncertain indications of pyrometers in furnace operations, and the inconveniences attending their use, the condition of furnaces as to the degree of heat is now commonly ascertained by trial pieces of the material operated upon, which pieces are so placed that they may be conveniently taken out for examination. They have a practical value, not attainable by instruments that merely indicate the degree of temperature, in showing the effect already produced upon the articles in the furnace.

PYROPHORUS (Gr. πῦρ, fire, and φέρω, to bear), a substance which takes fire on exposure to the air. This property is possessed by a number of substances and of mixtures specially prepared. Finely divided metals, as iron when reduced from the oxide at the lowest possible temperature by a current of hydrogen, exhibit it in a remarkable degree. The effect appears to be produced in all cases by rapid combination of the oxidizable substance with the oxygen of the air. An excellent pyrophorus is produced by calcining in a close crucible 6 parts of lampblack mixed with 11 of sulphate of potash; the product is a mixture of carbon and sulphuret of potassium. Homberg's pyrophorus is made by stirring a mixture of equal parts of alum and brown sugar in an iron ladle over the fire till it becomes dry; then heating the same in a red-hot vessel nearly closed as long as a flame appears at the aperture. It is then removed from the fire, and carefully stopped until required for the experiment. Tartrate of lead heated to dull redness in a glass tube becomes a brown powder, which when shaken out into the air instantly ignites. It is prepared from the solution of acetate or nitrate of lead by adding to it tartaric acid or a tartrate.

PYROTECHNY (Gr. πῦρ, fire, and τέχνη, art), the art of making fireworks for public exhibitions or for military purposes. Until the invention of gunpowder, and the properties of saltpetre were understood, fireworks may be said to have been unknown in Europe. But the Chinese from an early period were skilful in true pyrotechnic works. Their exhibitions of fireworks have long been of similar character to those now seen among the most advanced nations, and in their variety and the diversity of brilliant colors imparted to the lights they are still unsurpassed. Barrow in his "Travels in China" notices particularly the brilliant pyrotechnic exhibitions, and describes pieces unknown in Europe. One of striking effect was the descent from a box suspended at an elevation of 50 or 60 feet of strings of lanterns, which gradually unfolded themselves to the number of full 500, each one having a light of beautifully colored flame burning within it. From other boxes at the sides descended at the same time an immense network of fire divided into regular figures of the greatest diversity of form and colors, flashing in great splendor and constantly changing. "The whole concluded with a volcano or general explosion and discharge of suns and stars, squibs, crackers, rockets, and granadoes, which involved the gardens for above an hour in a cloud of intolerable smoke." From these exhibitions without doubt useful hints have been afforded for our own fireworks, and some of the materials employed, as the crackers particularly, have been largely exported from China to other countries.—In Europe the pyrotechnic art was first cultivated by the Italians; and it was described by Biringucci Vannoccio in his work, *De la pirotechnia*, published in 1540. In France the subject was treated by J. Hanzelet in his *Traités militaires* (1598). This writer recommended the use of the rocket in war, thus anticipating Congreve. The Chinese, however, had from an unknown period employed the rocket as an offensive weapon, affixing to its front end a pointed barb like that of an arrow. Among the earliest pyrotechnic displays of much note in Europe were the exhibitions at Fontainebleau by Sully in 1606, and by Morel, commissary of artillery, in 1612. The rejoicings at the establishment of peace in 1739 gave occasion for splendid exhibitions at the Hôtel de Ville and the Pont Neuf in Paris, and at Versailles. In the middle of the 18th century the Ruggieris, father and son, acquired great celebrity as artificers of fireworks, and their exhibitions at Rome and at Paris are considered to have been among the most brilliant ever witnessed. At Rome there is at Easter a famous annual exhibition of fireworks on the ramparts of the castle of San Angelo.—The compositions prepared for fireworks are too numerous to be even named in this article, and reference can be made merely to the materials commonly employed, with exemplifications of the manner in which they are compounded in a few of the principal pieces. Gunpowder and its ingredients, nitre, sulphur, and charcoal, are the chief constituents of fireworks. Iron and steel filings and cast iron borings, which must be free from rust, are used to increase the vividness of the combustion, and produce what is known as the Chinese "brilliant fire." It is these which are thrown out by rockets as they explode, and produce the bright sparks as they meet the oxygen of the air. Copper filings and the salts of copper give a greenish tint to the fire; zinc filings, a fine blue; sulphuret of antimony, a light greenish blue with much smoke; amber, rosin, and common salt protected against dampness, are used to give a yellow fire; a red is produced by lampblack, and a pink by nitre in excess; the salts of strontian also give a red color, and those of barytes a green. The fine seeds of *lycopodium clavatum*, one of the club mosses, burn with a vivid flash of a rose color, and are used in theatres to represent lightning, being blown from a tube through the flame of a lamp.—The most useful piece of fireworks is the sky rocket, employed as a signal, and under favorable circumstances visible no less than 30 leagues. (*Bulletin d'encouragement*, Aug. 1821.) As a warlike missile it will be treated under ROCKET. In exhibitions of fireworks the rocket is a luminous projectile, made to dart upward with immense velocity and a loud hissing sound, and explode at the top of its flight. It is sent up singly or in volleys of great numbers together, and as they explode each one commonly discharges colored lights which descend in brilliant showers, or dart forth in every direction with the irregular motions of the so called fusees and serpents. It is made of various compositions, which are packed in tubes formed by rolling paper hard round a cylindrical core and strongly pasting. The following are the compositions recommended for tubes respectively of ½ (A), ¾ to 1 inch (B), and 1½ inches diameter (C):

Ingredients.	Common rocket.			Brilliant fire.			Chinese fire.		
	A	B	C	A	B	C	A	B	C
Nitre	16	16	16	16	16	16	16	16	16
Charcoal	7	8	9	6	7	8	4	5	6
Sulphur	4	4	4	4	4	4	3	3	4
Fine steel filings	..	..	..	3	4	5	..	..	..
Fine borings of cast iron	..	..	..	.	..	..	3	4	5

At what is to be the lower end the tube is pinched in or "choked" to one third its diameter, and in this end is inserted a long, slightly conical iron spike, its upper pointed end reaching very near the top of the case. The spike is merely a temporary core, around which the composition is packed, and which being finally removed leaves a cavity of its own dimensions in the axis of the rocket. Sometimes the case is filled up solid and the cavity is bored out in the composition. As the composition must be powerfully rammed, the case is supported in a cylindrical mould of wood or copper, which it exactly fits. The rammer is of gun metal or of some material which will not strike fire, and is made hollow to admit the spike. It is driven with well regulated blows upon the composition, which is introduced a little at a time. The regularity of movement of the rocket depends on the charge being uniformly compact throughout. When the point of the spike has been entirely covered, a disk of doubled paper is laid over the charge, and the inner part of the case projecting above is turned down and rammed, thus making a close cover. This is, however, pierced with a few holes, and in the remaining receptacle are placed, together with some gunpowder, or with the same composition already employed, ornamental objects, as stars, sparks, &c., or for signal rockets merely gunpowder slightly rammed and connected by a single hole with the charge below. The top of the case is then turned in and securely pasted down. As this end is to go foremost, a cone of paper is attached to it to lessen the resistance of the air. For rockets carrying more of the "decorations," as serpents, crackers, &c., a cylindrical case of greater diameter than that of the rocket itself is fitted upon the upper end, which it encloses, and to which it is tightly secured by twine and paste. The match by which the rocket is to be fired is introduced into the cavity at the bottom, and the whole exposed surface of the composition forming the walls of the cavity is instantly ignited. The gaseous products, being violently ejected from the open end, react with equal force, carrying the rocket forward in the other direction. The movement however would be extremly wild if not controlled by some regulator. This is furnished in a long balance stick firmly tied to the rocket and projecting several feet behind. It is made of light wood, and when it is set free after the explosion it rarely falls with sufficient velocity to do any harm. Long triangular pieces of pasteboard have been secured by the edge to the sides of the rocket as a substitute for the stick, and have also served to steady its movement. Among the decorations or garnitures for the rockets are stars, small cylindrical or cubical bodies variously compounded, as of 1 part of sulphuret of antimony, 2 of quartz, 2 of gunpowder, 15 of nitre, 6 of sulphur, and 3 of zinc filings. The materials, being separately pulverized, are mixed into a stiff paste with gum water or glue, made into the desired shapes, rolled in gunpowder, and dried. Other compositions, which before using should be soaked in alcohol, are nitre 16, to 8 or 7 of sulphur, and 3 or 4 of gunpowder; or for golden showers, to the same proportion of nitre may be added sulphur 10 or 8, charcoal 4 or 2, gunpowder 16 or 8, lampblack 2. The selection of the latter figures, where there is a choice, will give showers more yellow.—Roman candles are cylindrical cases charged with stars alternating with a composition like that of the rockets, and with gunpowder. A small quantity of the composition is rammed into the bottom of the case, upon this a little gunpowder, and a star is then pushed down upon the powder. These charges are repeated in the same order until the case is filled. The end is then closed with a piece of match paper pasted round the outside and drawn to a point at the top. When this is fired the charges are shot at short intervals successively from the tube into the air. The effect is heightened by varying the compositions and colors of the stars. A red fire adapted for this or other pieces may be made by mixing 4 parts of dry nitrate of strontia with 15 of pulverized gunpowder; or this may be varied with 40 parts of the strontia, 13 of sulphur, 5 of chlorate of potash, and 4 of sulphuret of antimony. The usual precautions should be observed in pulverizing and mixing the chlorate of potash. A green fire like that burned in theatres, and which gives to every thing upon the stage a death-like aspect, is produced by 77 parts of nitrate of barytes, 13 of sulphur, 5 of chlorate of potash, 3 of pulverized charcoal, and 2 of arsenic.—Bengal lights, also called blue lights, and used by ships as night signals, are compounded of nitre 7 or 5, sulphur 2, antimony 1; or for the sparkling ones, 4 each of sulphur and nitre, 1 of antimony, and 2 of fulminating composition (of fulminating mercury and gunpowder). The proportions of these ingredients may be variously modified from those given.—Some of the most brilliant pyrotechnic displays are of wheels affixed to frames by a pin upon which they turn freely, the motion being caused by the reaction of discharges from tubes secured to the periphery or spokes. By varying the charges and introducing different colors, and by combinations of wheels, the most diversified and curious displays are produced. The Ruggieris were exceedingly ingenious in their devices of this character, and among other improvements they invented the method of causing one piece to ignite another and thus keep up a succession of exhibitions.—The published works on pyrotechny are mostly of the 17th and 18th centuries. Those of more recent date are: *L'art de faire à peu de frais les feux d'artifice* (Paris, 1825); *Manuel de l'artificier*, by A. D. Vergnaud (Paris, 1829); and "Pyrotechny," by G. W. Mortimer (London, 1852). The fullest work in English is an American book, "System of Pyrotechny, comprehending the Theory and Practice, with the Application of Chemistry," by James Cutbush (large 8vo., Philadelphia, 1825).

PYROXENE (Gr. πῦρ, fire, and ξένος, a stranger), a mineral species of Dana's augite section of the silicates, comprising numerous varieties. That to which the name was first applied, though found in the so called igneous rocks, did not occur, it was supposed, in modern lavas; whence the name. The species is an interesting one for its many varieties, which differ from each other in physical characters and chemical constituents, and consequently have been separated by different mineralogists among several species. They were first brought together under the head of pyroxene by Haüy, who recognized the identity of the crystalline form common to them all; and though for a time the relationship among them was not admitted by chemists, it was at last found that the differences in their composition resulted from the substitution of one isomorphous element for another, and that one general formula might be used to express the combination of silicic acid with one or more of the following bases (one replaced for another in any proportions), viz.: lime, magnesia, protoxide of iron, or manganese, and sometimes soda. Alumina may also enter into the composition, replacing it may be a portion of silicic acid, without essentially changing the crystallization. Among the varieties comprised in this species are the augites, coccolite, diopside, sahlite, Jeffersonite, and many others.

PYROXYLIC SPIRIT (also known as pyroligneous spirit or ether, wood spirit or naphtha, methylic alcohol, hydrate of methyle, &c.), a spirituous liquid, not a product of fermentation, but forming one of the most volatile constituents of pyroligneous acid, from which it is obtained in the process of purifying this acid by distillation. (See Acetic Acid, and Naphtha.) When purified, wood spirit is a colorless liquid of a penetrating empyreumatic odor, and a disagreeable burning taste. It is very inflammable, burning like alcohol with a blue flame. It mixes with water, alcohol, and ether in all proportions. It boils at 150°, and at 68° its specific gravity is 0.798; at 32°, 0.8179. The substance was first recognized by P. Taylor in 1812; but its properties were first explained by Dumas and Peligot in 1835. In Great Britain wood naphtha, not being subject to the excise duty, has been a valuable substitute for alcohol in various manufactures. By repeated rectifications over lime or chalk, and rejecting the latter portions in the distillations, it was obtained of strength varying from 60 to 90 per cent. of pure spirit, and of specific gravity from 0.87 to 0.82. From its property of dissolving the resins it was much used in the production of varnishes, lacquers, &c., and by the hatters for their solutions of shellac. The government now permitting the mixture of 90 parts of alcohol with 10 of purified wood naphtha to be employed free of duty under the name of "methylated spirit," the demand for the naphtha has greatly fallen off. The medical properties of wood naphtha are narcotic, sedative, and anti-emetic; and it has proved efficient in arresting or greatly mitigating chronic vomiting; also as a remedy in diarrhœa and dysentery, in doses of 10 to 40 drops in water 3 times daily. Though formerly recommended in pulmonary consumption, it is found to have no further effect than to palliate the cough and lessen the febrile excitement.

PYRRHA. See Deucalion.

PYRRHO, a Greek sceptical philosopher, a native of Elis, born probably in 375 B. C., died in 285. He was successively a poor painter, a poet, a disciple of the Megaric school, a student of the writings of Democritus, and a companion of the Democritean philosopher Anaxarchus, under whose patronage he joined the eastern expedition of Alexander the Great. He addressed a poem to that monarch, which was munificently rewarded with 10,000 pieces of gold. He accompanied the Indian campaign, and thus became acquainted with the doctrines and practices of the Indian gymnosophists, as well as those of the Persian magi. In the most active and important period of Greek philosophy he surveyed the results alike of Greek and oriental speculation only as a preparation for the establishment of a complete system of scepticism. He returned to Greece weary of the falsehood and vanity of the camp and court, and cherishing as the highest good the utmost repose and peace of mind. He lived in retirement, probably in his native city, and apparently in indolence, yet was honored by his countrymen with the office of high priest. For his sake, also, a law was passed exempting philosophers from the payment of taxes. His disciple Timon, who reported many conversations with him, extols with admiration his divine repose of soul, his independence of every thing external, and his lofty indifference to sophistry, and compares him to the imperturbable sun god dwelling above the earth. The only condition which he deemed worthy of a philosopher was that of suspended judgment. He would neither assert nor assent to any proposition. He and his followers were called inquirers, who sought the truth; sceptics or examiners, who always considered and never discovered; ephectics, from the state of suspense which they cherished; and doubters, from the logical dilemmas out of which they could not extricate themselves. Suspense was rather a practical than a speculative principle with him, and he refused to undertake any philosophical justification of it. His merit as a sceptical philosopher consists only in his rigorous adherence to the sceptical idea, which he developed into no system. No writings are attributed to him, except his poem addressed to Alexander. His doctrines were expounded by Timon, called by Sextus Empiricus his prophet.

PYRRHUS, son of Achilles. See NEOPTOLEMUS.

PYRRHUS, king of Epirus, born about 318 B. C., killed at Argos in 272. He was the son of Æacides and Phthia, and traced his descent from Pyrrhus, the son of Achilles, and was also connected with the royal family of Macedon. His father having been dethroned by the Epirotes, Pyrrhus was rescued and brought to Glaucias, king of the Taulantians, who educated him with his own children. When Cassander's power in Greece was weakened, his protector was enabled to restore Pyrrhus to his throne; but he did not long enjoy his sovereignty, as he was again expelled by the Epirotes, and fled to his brother-in-law Demetrius Poliorcetes, who was then in Asia. He distinguished himself at the battle of Ipsus in 301, and subsequently went into Egypt as a hostage for Demetrius. There he gained the good will of Ptolemy's wife, Berenice, married her daughter Antigone, and was furnished by the king with a fleet and troops to recover Epirus. He found Neoptolemus in possession of the throne, and the two consented to hold it in common; but presently, to prevent his own destruction, Pyrrhus put Neoptolemus to death (295). He now interfered in the quarrels of Antipater and Alexander, the two sons of Cassander, and took the part of the latter on condition that Acarnania, Amphilochia, and Ambracia should be ceded to himself, with the Macedonian districts of Tymphæa and Parauæa. He then placed Alexander on the throne of Macedon, but the latter was soon after dethroned and put to death by Demetrius, to whom he had also applied for aid, and who made himself king in his place. Hostilities soon arose between these two powerful neighbors, who had formerly been close friends. War broke out in 291, in which year Thebes revolted from Demetrius; and while the Macedonian king was engaged in the siege of that place Pyrrhus marched into Thessaly, but was forced to retire. Thebes having fallen in 290, Demetrius invaded Epirus in 289, leaving Pantauchus in Ætolia with a large force to keep the Ætolians in subjection. Pyrrhus, advancing to meet Demetrius, but taking a different route, entered Ætolia, encountered Pantauchus, and defeated his army, vanquishing him in single combat. The next year he invaded Macedonia, and marched as far as Edessa, but was driven back, and soon after concluded a peace with Demetrius, who was now anxious to regain his father's dominions in Asia. Hereupon Seleucus, Ptolemy, and Lysimachus entered into an alliance which they persuaded Pyrrhus to join, to attack the Macedonian king in his European dominions. Demetrius was forced to flee, and his kingdom was divided, a large share of Macedonia falling into the hands of Pyrrhus. Soon, however, the Macedonians drove him out again, and put themselves under Lysimachus. In 281 an embassy from the Tarentines implored Pyrrhus to come over to Italy and assist the Greek inhabitants against the Romans. He set out in 280 with an army of 20,000 foot, 3,000 horse, 2,000 archers, 500 slingers, and a number of elephants. But a great storm arose and scattered the fleet, and Pyrrhus arrived at Tarentum after nearly losing his own life. There, while waiting for the dispersed ships to come in, finding the inhabitants indisposed to take their proper share in the war, he compelled them to enter the army, closed their theatres, and soon showed himself their master as well as ally. Failing to negotiate with M. Valerius Lævinus, the Roman general, Pyrrhus met him on the river Siris and won a victory with the loss of a large number of his best troops. "Another such victory," he is reported to have said, "and I must return to Epirus alone." He now sent Cineas to Rome offering peace on condition that the independence of the Italian Greeks should be recognized, and that the Samnites, Lucanians, Apulians, and Bruttians should regain the possessions they had lost in war. Although many of their allies had deserted them at this time, and their condition seemed critical, the Roman senate rejected the terms. Hereupon Pyrrhus marched to within 24 miles of Rome, plundering the country as he went; but the arrival of the Roman army from Etruria placed him under the necessity of retiring. Taking up his winter quarters in Tarentum, he took the field in the spring of 279, and gained a hardly won victory at Asculum. Few of his Grecian troops were now left; and, unable to obtain reënforcements from home, he was willing to conclude a truce in order to drive the Carthaginians from Sicily. Previously the Roman consuls Fabricius and Æmilius had sent back to Pyrrhus a servant who had deserted and promised to poison his master, and in return for this Pyrrhus released all the Roman prisoners. He now passed over into Sicily, and at first was so successful that the Carthaginians agreed to assist him with ships and money against the Romans on condition of peace. But rejecting this offer, and shortly after failing in an attack upon Lilybæum, his credit so much declined, and with it his fortune, that he was glad to return to Italy in 276. His fleet was attacked by the Carthaginians, and 70 of his ships destroyed. He remained in Italy, carrying on an indecisive war, until 275, when he was routed near Beneventum by Curius Dentatus, and obliged to return to Epirus, having become poor both in troops and resources. In 273 he invaded Macedonia, and for the second time gained possession of that country. At the instance of Cleonymus, who had been excluded from the Spartan throne, he marched into Laconia in 272 with 25,000 foot, 2,000 horse, and 24 elephants. Against such a force resistance seemed useless. He arrived before Sparta at the close of day, but deferred the attack until the following morning. During the night the Spartans succeeded in fortifying themselves so strongly as to be able to hold the city until relieved by the arrival of reinforcements. Taking up his winter quarters in Laconia, Pyrrhus was induced to interfere in the affairs of Argos, and in a conflict in the streets of that city he received a slight wound from a javelin. He was about to cut down the Argive who had attacked him, when the mother of the man, seeing the danger of her son, hurled down from the roof of a house a large tile which struck Pyrrhus on the back of the neck. Stunned by the blow, he fell from his horse and was killed by some of the soldiers of the enemy, by whom he had been recognized. Pyrrhus wrote commentaries, which were used by Dionysius and Plutarch, and also composed a treatise on the art of war, which was extant in the time of Cicero.

PYTHAGORAS, a Greek philosopher, founder of a philosophical, religious, and political association in southern Italy, born in Samos about 580 B. C., died probably in Metapontum about 504. The absence of any writings proceeding from himself, the few contemporary memorials of him, the mystery which veiled the constitution and conduct of his brotherhood, the extravagant legends which prevailed concerning him and were adopted by his Neo-Platonic biographers, and the consequent confusion of different ages of Pythagoreanism, make him one of the most obscure personages in Greek history. A uniformity, however, prevails throughout his philosophy, by whomsoever developed, the germs of which, at least, must have been derived from himself, while his personal authority appears also in the sway which his societies long exercised over the Italian cities. He was the son of Mnesarchus, an opulent merchant, was a disciple of Pherecydes of Syros, and perhaps also of Thales and Anaximander, and is said to have spent 30 years in wide-reaching travels for the purpose of collecting all attainable knowledge, especially the esoteric doctrines of priests concerning the worship of the gods. Egypt, Arabia, Phœnicia, Judæa, Babylon, and even Gaul and India, are mentioned among the countries in which he travelled. Grote decides that he probably visited Egypt, and that he may there have derived from conversation with the priests, and from initiation into the various mysteries, his turn for symbolical ceremonials and ascetic practices. It is asserted by a few scholars that nothing either in his doctrine or institutions implies an oriental origin or any foreign influence. His contemporary Heraclitus said of him: "He has made more inquiries than any other man; he has acquired wisdom, knowledge, and mischievous refinement." Xenophanes, also his contemporary, related that he believed in the metempsychosis, or transmigration of souls, and that seeing a dog beaten, and hearing him howl, he begged the striker to desist, adding: "It is the soul of a friend of mine, whom I recognized by his voice." Later authorities ascribe to him the discoveries that the triangle in a semicircle is right-angled, and that the square on the hypothenuse of a right-angled triangle is equal to the sum of the squares on the other two sides, and also discoveries in the theory of music and in medicine. Apart from authentic testimony, it is probable from the character of his followers that he was especially skilled in geometry and arithmetic, and that the Pythagoreans were taught by him to regard numbers as in some mysterious manner the basis and essence of all things. It was however rather as a religious teacher than a philosopher that he made his profound impression upon his contemporaries; and while the druids of Gaul, the gymnosophists of India, or the priests of Egypt and Phrygia have been regarded as the source of his religious doctrines, it is supposed by Ritter that he derived by tradition a secret mystical cultus which he rather developed than modified. He is said to have returned to Samos when about 40 years of age, with religious zeal the predominant element in his character. His native island, under the despotism of Polycrates, was unfavorable to the dissemination of his doctrines, and he emigrated to Crotona in Italy, then distinguished for the superiority of its physicians and the excellent *physique* of its citizens. There is no evidence to confirm the statements of Porphyry and Iamblichus that he withdrew because the public honors conferred on him by the Samites interfered with his schemes in behalf of religion and philosophy. He immediately acquired personal ascendency on reaching Crotona. At his first eloquent discourse no fewer than 2,000 persons are said to have been converted, and the aristocratic council of 1,000 persons, in which the supreme authority was vested, offered to him its presidency. From the marvellous stories of his biographers there is reason to believe that he was received as a person favored by the gods and as a revealer of divine secrets; that he was at once revered by the multitude and honored and obeyed by numerous adherents of the powerful and wealthy classes; that he formed a brotherhood of 300 bound by a vow to a peculiar diet and by common religious observances and hopes; and that this club of influential men gradually and successfully mingled political with religious and scientific motives. That he required a long novitiate of silence, possessed a remarkable skill in reading character, instituted a peculiar diet and discipline, rigidly cared for sobriety as conducive to physical vigor, and employed music to soothe the passions, are mentioned among the sources of his power. The whole discipline was designed to produce a lofty serenity and self-possession, and to raise its votaries above the level of mankind. It does not appear, however, that all were subjected to the same training or studies, since Milo, the most famous wrestler of his age, was among them, and could not have dispensed with animal food. The Pythagoreans soon became ascendant in the government of Crotona, and exerted their power in favor of the aristocratic party. Proud of the religious ideas and ethical tone of their master, they were haughtily exclusive, physically and intellectually efficient, and politically domineering. Kindred clubs were established at Sybaris, Metapontum, Tarentum, and other cities, and the doctrines and influence of Pythagoras spread rapidly over Magna Græcia. Concerning the internal administration of the brotherhood little is certainly known, since every thing that was done and taught was kept a profound secret. The members are usually divided into the esoteric and the exoteric, the former being, according to Ritter, specially instructed in the religious rites and doctrines, in the more recondite Pythagorean speculations. The daily routine, as given by Iamblichus, resembles the discipline of Spartan citizens. Müller calls the Pythagorean discipline the expression of Grecian Dorism as opposed to Ionic tendencies. Lobeck maintains the identity of the Pythagorean and the Orphic life, regarding the latter as only the modification of the former after it was transplanted to Greece. The political prominence of the Pythagoreans, and the democratic jealousy caused by their aristocratic exclusiveness, led to their overthrow. The war which resulted in the conquest of Sybaris (510 B. C.) was undertaken by their advice, and the Crotonian forces were commanded by their athlete Milo. The victory encouraged them to resist more actively than before the attempt of the popular party to obtain a share in the government of Crotona, and they gave signal offence by refusing to divide among the people the territory of the recently conquered city. Their enemies ventured upon determined opposition to them, and the result was a revolution by which a new senate was constituted, taken by lot from all the people. The popular party was now unrestrained, and the Pythagoreans were attacked in their assembly house, the building set on fire, and all but the younger and more vigorous members perished. The order was in like manner violently suppressed in the other cities of Magna Græcia, having endured about 20 years. Yet it continued to exist as a philosophical sect, devoted to religious and scientific interests. Pythagoras himself is variously stated to have been burned in the temple with his disciples, to have died a short time previously, and to have perished long afterward in exile at Metapontum after 40 days of voluntary abstinence from food. According to Müller, "the influence of the Pythagorean league upon the administration of the Italian states was of the most beneficial kind, which continued for many generations after the dissolution of the league itself."—The first publication of the Pythagorean philosophy was made by Philolaus and Archytas, contemporaries of Plato, and among the last members of the expiring sect, from whom nearly every thing trustworthy on the subject seems to have been derived. It was exaggerated and distorted by Apollonius of Tyana and the Neo-Pythagoreans from the age of Cicero, who were rather thaumaturgists than philosophers, and who were gradually confounded with the Neo-Platonists. The fundamental doctrines are, that the essences of all things rest upon numerical relations; that numbers are the principle of all that exists; and that the world subsists by the rhythmical order of its different elements. Everywhere in nature appear the two elements of the finite and the infinite, which give rise to the elementary opposites of the universe, the odd and even, one and many, right and left, male and female, fixed and moved, straight and curved, light and darkness, square and oblong, good and bad. The essence of number is unity, which is at once odd and even, and contains in itself in germ all the universe. It is at once the form and the substance of all things, and identical with the Deity. Proceeding from itself it begets duality, and returning upon itself it begets trinity. Added to itself it produces the line; a third point placed on the other two gives the surface; and a fourth point placed on the other three gives the pyramid or solid. The quadrate or tetractys and the decade are, like unity, sacred numbers and first principles. The universe was produced by the breathing of the first principle into the infinite void of the world, which thus became both finite and infinite, and therefore capable of development into a multiplicity of numbers or things. In the actual world every single whole is a unit, capable of further development by the vital process of breathing. Every abstract idea is a number, and material objects are symbols of numbers. There are 5 elements, the earth, fire, air, water, and ether, represented respectively by the cube, pyramid, octahedron, icosahedron, and dodecahedron. The universe is a harmonious whole, consisting of 10 great bodies revolving in a choral dance around a common centre, and producing by their harmonious movements the music of the spheres. The centre is the sun, the seat of Jupiter, the principle of life, and the most perfect object in nature. The stars also are divinities, and men and even inferior animals are akin to the Supreme Being. The souls of men are moving numbers, light particles from the universal soul, capable of combining with any body, and destined to pass successively through several. With the theory of metempsychosis he combined the doctrine of moral retribution. The reason and understanding have their seats in the brain; the passions are placed in the heart. Moral good was identified with unity, evil with multiplicity; virtue was the harmony of the soul and its similitude to God. The aim of life was to make it represent the beautiful order of the universe. The whole practical tendency of Pythagoreanism was ascetic, and inculcated a strict self-control and an earnest culture. Though it seems to have been founded on the mysticism of numbers, yet it was regarded as a scientific doctrine by Aristotle, who called the Pythagoreans a school of mathematicians.—Pythagoreanism was of little account in the scholastic philosophy, but its doctrines of numbers were recognized in the mysteries of alchemy, and in the symbols of mystical architecture. To Albert of Strasbourg was attributed a complete scientific, moral, and architectural system founded on numerical relations. At the revival of learning Pythagorean tenets lay at the basis of the speculations of Nicholas of Ousa, and mingled with those of Giordano Bruno. In the present century Joseph de Maistre has developed anew the mysterious qualities of numbers, and Leroux's doctrines of the triad and of the metempsychosis recall the speculations of Pythagoras.

PYTHEAS, a Greek navigator of Marseilles, who flourished about the age of Alexander the Great. He is said to have made two voyages, in one of which he visited Britain and Thule (perhaps Iceland), and in the second passed along the western and northern coast of Europe. He also wrote two books, one of which, describing the ocean, was probably an account of his first voyage, and the other, entitled *Periplus*, of his second. In these works he stated that he had visited Britain, and that it was 40,000 stadia in circumference. Moreover, he said that in Thule the days and nights were 6 months long, and that in the summer solstice the sun never disappeared from the horizon. The Tanaïs to which Pytheas refers is probably the Elbe. By many ancient writers, especially Polybius and Strabo, the statements of Pytheas are treated with contempt, the latter in several places calling him a great liar; but in modern times it has become evident that he was a bold navigator and sagacious observer. He was the first who determined the latitude of a place from the shadow cast by the sun, obtaining the position of Massilia by means of a gnomon. He was also aware of the influence of the moon upon the tides. The few fragments of Pytheas now extant were collected by Arvedson (Upsal, 1824).

PYTHIA. See DELPHI.

PYTHIAN GAMES, one of the 4 great national festivals of Greece, held at Delphi, which was originally called Pytho from the serpent Python killed by Apollo near there. The legendary account attributed the origin of these games to Apollo, although there were traditions also referring them to Amphictyon, Diomedes, and other heroes. At first the Delphians themselves decided the disputes and adjudged the prizes, but after the Crissæan war the management came into the hands of the Amphictyons. Once, in Ol. 122, the games were held in Athens by the advice of Demetrius Poliorcetes. They appear to have lasted as long as the Olympic games, or till about A. D. 394. They were held in the Crissæan plain, which had a theatre for the musical contests, a race course, a stadium 1,000 feet long, and probably a gymnasium, prytaneum, and similar buildings. Some ancient writers tell us that they were first called Pythian games in Ol. 48, when the Amphictyons assumed their management. Previously they had been held at the end of every 8 years, but afterward at the end of every 4. They were probably solemnized in the spring, and lasted several days. There were other Pythian games of less importance held in various places in Greece, in Asia Minor, and Italy, where the worship of Apollo was established.

PYTHIAS, See DAMON.

PYTHON (Daudin), a genus of large tropical, non-venomous serpents, replacing in the old world the boas of the new. (See BOA.) The pythons differ from the boas in having 4 teeth in the intermaxillary bone, and in most of the subcaudal scales being in pairs. Most of the species of these large serpents have been exhibited alive in European and American zoological gardens and menageries, though in this country they are far less commonly seen than the South American boas. The python of Java (*P. reticulatus*, Gray) is one of the handsomest of the genus, being laced with brilliant golden and black; it attains a length of 30 feet, and possesses sufficient strength, it is said, to overcome the buffalo. The Indian rock snake (*P. molurus*, Gray) attains a similar size; it is marked above with yellow, black, and brown, and is white beneath spotted with black; it is the *oular sawa* of the Malays; it frequents rice fields and marshy places, and feeds principally on hogs and muntjacs. In Africa belongs the Natal python or rock snake (*P. Natalis*, Smith), from the vicinity of Port Natal; it attains a length of more than 25 feet and the thickness of a man's body; the South Africans have such a superstitious dread of it that they will seldom attack it even when powerless from being gorged with food. Seba's or the two-banded python (*P. bivittatus*, Kuhl) has 2 brownish black bands along the sides of the back; it attains a length of more than 20 feet, and is especially abundant in the Senegal region. The royal python (*P. Bellii*, Gray), from the same localities, is a brightly marked species, of a shorter and thicker form.

Q

Q, the 17th letter and 18th consonant of the English alphabet. It corresponds with the Hebrew and Phœnician *koph*, and as it is seldom used except in conjunction with *u*, most grammarians are disposed to regard it as a superfluous letter whose place could be supplied by *k*. It does not occur in the Greek, old Latin, Slavic, Irish, or Saxon alphabet, though it was introduced into the Latin at a pretty early period. The words which are now written with a *q* were spelt by the ancient Romans with *c*, as *anticus* for *antiquus*, *cotidie* for *quotidie;* and some words are still spelt indiscriminately with either, as *locutus* or *loquutus*. Varro and some other grammarians never consented to admit this letter into the Roman alphabet. Others regarded it not as a simple letter, but as a contraction of *cv* or *cu;* thus *quis*, according to them, was originally *cvis* or *qis*. The Anglo-Saxons for *qu* wrote *cw*. Q never ends a word in English, but it does in French, as *cinq*, and in other modern European languages. The letters with which it interchanges are *c* and *k*. As a numeral it stands for 500, or with a dash over it ($\bar{Q}$) for 500,000. Used as an abbreviation, it signifies *quantum*, *quod*, *quæ*, *que* (and), Quintus, &c.

QUA BIRD. See Night Heron.

QUACKENBOS, George Payn, an American educator, born in New York in 1826. He was graduated at Columbia college in 1843, and soon after commenced teaching in North Carolina. He has continued in this profession with a brief interval ever since, having in 1847 opened a private school in New York city, and has beside been connected with various journals as contributor, correspondent, and editor. In 1848 he established the "Literary American," which he conducted for two years. He has published a number of popular school books, including an "Advanced Course of Composition and Rhetoric" (1854); "Illustrated School History of the United States" (1857); "A Natural Philosophy for Schools and Academies" (1859); and "Primary History of the United States" (1860); and has prepared an American edition of Spiers and Surenne's French and English dictionary (1852).

QUADI, an ancient powerful people of S. E. Germany, of the Suevic race. They inhabited the country between Mount Gabreta, the Hercynian forest, the Sarmatian mountains, and the Danube, their neighbors being the Gothini and Osi on the N., the Jazyges Metanastæ on the E., the Pannonians on the S., and the Marcomanni on the W. With the last named people they were on terms of alliance. In the reign of Tiberius the Romans erected a kingdom of the Quadi between the rivers Marus (March?) and Cusus (Waag?), gave the
to Vannius, who belonged to that tribe
kept it for a long time under their prote
but in the reign of Marcus Aurelius the Q
joined the great German confederacy a
the empire, and in 174 were on the poi
destroying the imperial legions in a great b
when a sudden storm, attributed to the pr
of the Christian soldiers in the emperor's a
enabled the Romans to recover from their
fusion and achieve a complete victory. I
independence of the Quadi was recogniz
Commodus in 180. They disappear from
tory about the close of the 4th century.

QUADRANT, the fourth part; com
applied to the fourth part of the circle
arc of 90°, and also to instruments em
for measuring angles in any plane. The u
quadrants has been for surveying and for
ing astronomical observations, and espec
navigation for determining the meridian
tude of the sun and through this the lati
of the observer. They have been constr
of a great variety of forms and dimen
adapted for their several uses; but at pre
the interest attached to them is historical
as they have been entirely superseded either
sextants or the full circle. The former
more portable form than the quadrant, by
use of two reflecting mirrors double the
included between the direct and reflected
of light, and thus with an arc of 60° or
the circle include a range of 120°; while
circle, on account of the symmetry of its
and the completeness of its graduated ar
around, secures greater exactness in its rea
ings, and is less liable to the introductio
any unsuspected source of error. Quadr
were employed as far back as the time
Ptolemy, who made use of one for determi
the obliquity of the ecliptic. Tycho Br
had a large mural quadrant (so called from
being suspended upon an axis secured in a
wall of masonry) with which he observed a
tudes, and also another on a vertical axis
measuring horizontal angles. The mural quad-
rants of that period were large instruments
6 or 8 feet radius, and for some time continu
to be employed in the principal observatories.
Sir Isaac Newton is said to have constructed a
reflecting quadrant as early as the year 16
but the first instrument of this character brou
before the public was that afterward known
Hadley's, the invention of which was claimed
by Godfrey, a mechanician of Philadelphia.
(See Godfrey, Thomas, and Hadley, John.)
This instrument, which has been in general
use in navigation, is a graduated octant of
half degrees, reading as 90° With the radi

bars at each extremity of the arc it forms a triangular frame, which is made of convenient dimensions for holding in the hands. A movable radial bar or index revolves in the plane of the sector upon a pin passing through the centre. At the centre it carries a mirror, the face of which is perpendicular to this plane, and which in making an observation is turned toward the object, as the sun or a star, and at the other end it carries a vernier for subdividing the angles on the graduated limb. Upon the outer edge of the radial bar, back of the movable mirror, is set the sight vane, which is directed across to a second mirror fixed upon the opposite bar, its plane perpendicular to that of the bar, and its face so adjusted that a ray reflected from the first mirror to the second is transmitted from this to the eye at the sight vane. Only half of the glass of the second mirror, called the fore horizon glass, is silvered, and consequently rays passing through it from any object, as the horizon at sea, meet the eye in a direct line; and if at the same instant, while the instrument is held in this position, the index is moved so as to bring the reflected image of the sun upon the silvered part of the glass and from this to the eye, the reading of the vernier is the elevation of the sun above the horizon. Various other appendages are introduced in the quadrant, as a telescope for the sight vane, colored glasses for diminishing the intensity of the light, and a third mirror called the back horizon glass, with its sight vane, for taking a back observation. (For Gunter's quadrant, see GUNTER.)—In gunnery, the quadrant or gunner's square is a rectangular frame with a graduated arc between the two limbs. One of the limbs is extended beyond the arc, so as to be set into the mouth of the piece, the elevation of which it is to measure. A plummet suspended from the point of meeting of the two arms marks by the intersection of its line on the graduated arc the degree of elevation.

QUADRATURE, the finding of a square equal in area to that of any given figure. No mathematical problem has excited so great interest as the quadrature of the circle, or the determination of a square of the same area. As it is proved that the area of a circle is equal to that of a right angled triangle, the altitude of which is the radius of the circle and the base its circumference, and as the side of the square of equal surface with the triangle is a mean proportional between the height and half the base of the triangle, the problem would be solved if the circumference could be immediately calculated from the radius which is known. Thus the question of the quadrature of the circle is reduced to finding the proportion between the diameter and circumference. Archimedes undertook the solution of the problem on the principle of calculating the peripheries of two polygons of many sides (as 96), one circumscribed about the circle and the other inscribed, between which must lie the circumference of the circle. He thus found that the ratio of the diameter of the circumference lay between $1 : 3\frac{10}{71}$ and $1 : 3\frac{1}{7}$, and he adopted the former, which is also expressed 7 : 22. The Hindoos at some early period—certainly before any improvement was made upon this result in Europe—obtained the proportion 1,250 : 3,927, or 3.1416, which is much more exact than that of Archimedes. Ptolemy gives 3.141552, which is not quite so correct. In modern times the first great step in extending this calculation was made by Peter Metius, a Hollander, and was published by his son Adrian Metius. By calculating from polygons of about 1,536 sides he found that the proportion was less than $3\frac{17}{120}$ and greater than $3\frac{15}{106}$; and presuming that the mean of these was nearer the truth than either limit, he happily hit thus by chance on a near approximation, and determined a ratio convenient for practical purposes, and easy to recollect from its terms being made up of successive pairs of the first 3 odd numbers, viz.: 113 : 355. The error involved in this expression in a circle of 1,900 miles circumference is less than one foot. Ludolph van Ceulen, another Hollander, in 1590, about the same time that Metius made his calculations, extended the calculation to 36 figures, which are engraved upon his tombstone in Leyden. These are 3.14159265358979323846264338327950289. The last figure is too large, and 8 would be too small. This was obtained by calculating the chords of successive arcs, each one being half of the preceding; for the above result this was carried out so far, that the last arc was one side of a polygon of 36,893,488,147,419,103,232 sides. The method of calculation was greatly simplified by Snell, who carried the computation to 55 decimal places by means of a polygon of only 5,242,880 sides. By other mathematicians the computation was carried on, reaching successively during the last century 75, 100, 128, and 140 places of decimals; and Montucla received from Baron Zach 154 figures, said to have been obtained from a manuscript in the Radcliffe library at Oxford, of the existence of which there is no other evidence. The figures, however, except the last two, have since been proved correct. (See Montucla, *Histoire des recherches sur la quadrature du cercle*, 1754.) Notwithstanding that Lambert in 1761, and still later Legendre in his *Éléments de géométrie*, proved that the ratio of the diameter to the circumference cannot be expressed by any numbers, the wish to satisfy those who still sought the exact expression of this ratio led other mathematicians to continue to add to these figures; and some must have derived a singular gratification in the computation itself and its never terminating result. In May, 1841, a paper was communicated to the royal society by Dr. Rutherford of Woolwich, presenting 208 figures of decimals, of which however 56 were afterward proved to be wrong, so that the series was not really carried beyond the result obtained from the Oxford MS. In 1846 200 decimals were correctly made out by Mr. Dase; and the next year 250 by Dr. Clausen of Dorpat. In 1851 Mr. William Shanks of Durham calculated 315 decimals, which Dr. Rutherford verified and extended to 350. Mr. Shanks soon carried these to 527 decimals, of which 411 were confirmed by Dr. Rutherford. Finally in 1853 Mr. Shanks reached the number of 607 decimals, and gave the result in his "Contributions to Mathematics" (London, 1853).—When it was made evident that the arithmetical expression was impossible, it was still hoped by many that the ratio might be determined by geometrical construction; and the bare possibility of this, which a few mathematicians have admitted, has given encouragement to some to seek the solution in this direction. But this, too, is now generally admitted to be impracticable.—Little benefit has resulted from the vast amount of time and labor that have been expended upon this famous problem. Wallis, investigating it at a time when the nature of the subject was not so well understood, and the investigation was consequently a proper one, was led to the discovery of the binomial theorem; but most of those who have since interested themselves in the question understood too little of the mathematical sciences to avail themselves of any opportunity that might be presented of increasing the means of mathematical research. The academy of sciences at Paris in 1775, and soon after the royal society in London, to discourage this and other similarly futile researches, declined to examine in future any paper pretending to the quadrature of the circle, the trisection of an angle, the duplication of the cube, or the discovery of perpetual motion.—The fullest and latest *resumé* of the history of the quadrature of the circle is to be found in Knight's "English Cyclopædia" (London, 1861).

QUADRIO, Francesco Saverio, an Italian scholar, born in the province of Valtellina in 1695, died in Milan in 1756. At the age of 20 he entered the society of Jesus, taught philology at Padua and theology at Bologna, preached at Venice and Modena, and at Padua engaged in the work of writing a general history of poetry in all ages and countries, which was completed after many years under the title of *Storia e ragione d'ogni poesia* (7 vols. 4to., Bologna and Milan, 1741-'52).

QUADRUMANA (Lat. *quatuor*, four, and *manus*, hand), a division of mammals including the apes or monkeys and lemurs, so called from their having a grasping hand on each of the 4 extremities, as distinguished from the *bimana* or the human races in which the anterior limbs only have hands. The characters of the different families are given in the articles Ape, Baboon, Chimpanzee, Gorilla, Lemur, Lori, Macaque, Marmoset, Monkey, and Orang-Outang. While the chimpanzee and gorilla approach the human type in many points of organization, being however more distant from man than is the rudest savage from the most cultivated scholar, others, like the lemurs, seem to form the links between bats, carnivora, or insectivora, and the monkeys proper; all are truly quadrupeds, for anatomical reasons given under Anthropology and Ape. For details on the anatomy and physiology and extensive bibliography of the order, see the article "Quadrumana" by Vrolik in vol. iv. of Todd's "Cyclopædia of Anatomy and Physiology" (London, 1848). They are almost exclusively confined to the tropical regions of the earth, and feed mostly on vegetable food in a state of nature, even the largest and most ferocious species, and are generally arboreal in habit and gregarious. The quadrumana have in a few instances been found fossil, in the tertiary strata of Europe and Asia, and in the caverns of Brazil; their remains have been discovered in England and France, in a climate where now they could not exist in a wild state; it is worthy of notice that their fossil distribution is in one respect the same as the present, the *catarrhini*, or those with a thin partition between the nostrils and 32 teeth, being peculiar to the old world, and the *platyrrhini*, with more widely separated nostrils and 36 teeth, to America. In 1860 two new varieties, if not species, of large anthropoid apes were described by Mr. P. B. Du Chaillu, who discovered them in equatorial Africa. One of these is a chimpanzee-like animal, called *kooloo-kamba* by the natives from its peculiar cry, and found in the mountainous region of the interior near the head waters of the Ovenga river, in the almost uninhabited Ashankolo range. The height is about 4½ feet, and the general color is black; the features are more human than in the chimpanzee or gorilla, the head being rounded, the frontal ridge not very prominent, the cheeks rather hollow with projecting malar bones, the muzzle not very full, and the chin rounded, resembling very much a black Chinaman; the face is surrounded by whiskers meeting under the chin, adding still more to the human expression; chest broad; the arms reaching below the knee and indicating great muscular strength, the hands long and narrow, the thumb very short, and the knuckles callous as in the gorilla; legs short and without calf, and toes free like the fingers, indicating its arboreal habits. This rare animal its discoverer names *troglodytes kooloo-kamba*. The other large ape is the bald-headed nshiego, named *T. calvus* by Mr. Du Chaillu; it is about 4½ feet high, of a general blackish color, with the lower part of the back grayish, and a tendency to the latter color in old age; the most striking peculiarity is the baldness of the top of the head, found even in young specimens; a very scanty beard under the chin; the face is black in the adult, but pale in the young. It is found in the interior of Africa, south of Cape Lopez, especially in the Camma country; it builds a shelter in trees 20 to 30 feet from the ground; it ties branches together with wild vines and attaches them in an umbrella-like form to the trunk at a convenient distance above a horizontal branch on which it rests and sleeps; the male lives under one shelter, and the female under another, on a neighboring but not contiguous tree; the horizontal branch is always high, and the first from the ground, probably to secure the animal against the leopard of the country. Both of these animals will be found more minutely described in Mr. Du Chaillu's "Explorations in Equatorial Africa" (8vo., New York, 1861).

QUÆSTOR (Lat. *quæro*, to accuse), the name given to two classes of officers at Rome, the *quæstores parricidii* and the *quæstores classici*. The former of these, who have sometimes been confounded with the *perduellionis duumviri*, had their origin in the time of the kings, although under which monarch is uncertain. Their duty was to bring accusations against any person charged with a capital offence, and if he were found guilty to execute the sentence. After the establishment of the republic, *quæstores parricidii*, who seem before to have been appointed only at critical periods, were elected regularly every year by the curies, on presentation of the consuls. After the decemvirate they were appointed by the centuries, and at the passage of the Licinian laws they ceased to exist, their functions being transferred to the *triumviri capitales* and also to the ædiles and tribunes. From their early disappearance from history they were frequently confounded with the *quæstores classici*, the officers who had the charge of the public money. These registered and exacted all fines, provided accommodations for foreign ambassadors and for persons connected with the republic by the ties of hospitality, took charge of the funerals and monuments of illustrious men who were buried at the public expense, and kept the books in which the copies of the senate decrees were registered, the original documents being in the care of the ædiles until the time of Augustus, when they were given into the hands of the quæstors. This office is said to have been instituted by Valerius Publicola, and could only be held by patricians until 421 B. C., when the number, which previously had been two, was doubled, and the choice was not confined to either order. It was not until 10 years later, however, that any plebeians were elected. Afterward the consuls in their campaigns were attended each by one quæstor, who originally took charge only of the sale of the spoils, but subsequently became the paymaster of the army. The two quæstors who remained at Rome were distinguished by the title *urbani*. In 265 B. C. the number of quæstors was raised to 8, one of whom resided at Ostia and had the important duty of supplying Rome with corn. After this the number varied. By Sylla it was raised to 20, and by Julius Cæsar to 40. In 49 B. C. the latter also transferred the administration of the public treasury to the ædiles, no quæstors being elected; and thenceforth the treasury was sometimes under the charge of the prætors, sometimes of prefects of the treasury, and sometimes again of the quæstors. During the empire the number of quæstors varied, and among them are mentioned those entitled *candidati principis*, whose sole duty was to read to the senate the communications which the emperor made to that body. From the reign of the emperor Claudius it became the custom of quæstors on assuming their office to give gladiatorial spectacles to the people, so that none but wealthy men were eligible; and the custom also prevailed in Constantinople, after it became a capital of the empire.—Every prætor or proconsul was attended in his province by a quæstor, who, beside being paymaster of the army, was charged with the raising of that portion of the revenue which was not farmed out to the *publicani*, and with the control of the latter also. When the quæstor died in the province, the prætor appointed a proquæstor in his stead; and when the prætor was away, the quæstor took his place, in which case he was attended by lictors. In the provinces of the Roman people, the quæstor had the same jurisdiction as the curule ædiles at Rome, and therefore the power to promulgate edicts; but in the provinces of the emperor there were no quæstors, their places being supplied by procurators. During the reign of Constantine, the title of *quæstor sacri palatii* was given to an officer in the imperial court, whose functions were somewhat analogous to those of a modern chancellor.—Any person who had held the office of quæstor was entitled to a seat in the senate, unless excluded by the next censors.

QUAGGA, a species of zebra, belonging to the asinine division of the horse family, and to the genus *asinus* as defined by Gray, characterized by a tail furnished with long hair only at the tip, the absence of horny warts on the hind legs, and a short and upright mane. The quagga (*A. quagga*, Gray) is about 4 feet high at the shoulders; the neck and anterior parts of the body are dark brown, elegantly striped with broad black bands; the rest of the body paler brown, belly and legs white; a dark median line on the back extending to the tail. This beautiful species associates in large herds with the gnu and ostrich, but not with other zebras, on the plains of S. Africa, and is rarely found north of the Gariep or Orange river; it is the most horse-like in structure of any of the group, having the form, light figure, and small head and ears of the horse, with the tail of the ass; its appearance is so equine that Buffon regarded it as a hybrid between a horse and a zebra. It is swift, and rather shy in its native state, strong, robust, and bold when attacked by hyænas or dogs; the voice resembles a barking neigh more than a bray, and has given to the animal the Hottentot name of quagga. It is the most easily domesticated of the zebras, and is docile, generally good-natured, and obedient, disposed to kick, however, at the sight of a dog; in 1827 a curricle drawn by two quaggas was one of the most attractive equipages in Hyde park, London. A little care on the part of man would probably render the quagga a very serviceable beast of burden, and under a climate where horses suffer both from the heat and noxious insects. Its flesh is eaten by the natives and by hunters, and is considered very good, though the fibre is coarse.

QUAIL, the common name of several genera of the partridge division of gallinaceous birds. The American quails constitute the sub-family of *odontophorinæ* or *ortyginæ*, which have a short, high, and arched bill, compressed on the sides, with obtuse tip, the upper overhanging the lower mandible, and the latter with two teeth on each side concealed when the mandibles are closed; the wings moderate, concave, and rounded; tarsi generally slender, shorter than the middle toe, and covered with divided scales; toes long, the inner shorter than the outer; claws slightly curved and acute. In the genus *ortyx* (Steph.) the head is without crest, the bill broad, the 3d quill nearly as long as the 4th, 5th, and 6th, which are longest; tail short, broad, and rounded; toes slender, slightly united at the base by membrane; hind toe moderate and slightly elevated. There are about a dozen species, found in North and Central America and in the West Indies; they seek their food on the ground among the leaves, eating grains, seeds, berries, and insects, which they swallow with small pebbles or fine sand. The common quail, or Bob White (*O. Virginianus*, Bonap.), is about 10 inches long, with an alar extent of 15; the general color above is brownish red, especially on the wing coverts, tinged with gray and mottled with dusky on the upper back; chin, throat, forehead, and line through the eyes and along the sides of the neck, white; a black band across the top of the head, extending backward on the sides, and from the bill below the eyes crossing on the lower part of the throat; below white, tinged with brown anteriorly, each feather with black bands; the female has not the black marks, and the white on the head is replaced by brownish yellow. It is found abundant in the eastern United States to the high central plains; the northern birds are largest and lighter colored, the southern with more black on the head, wings, and back; a smaller and more grayish variety in Texas has been separated as a species. The flight is rapid, low, and with numerous quick flappings. It takes to trees when alarmed, a flock dispersing in all directions and afterward coming together at the call of the leader. The males are very pugnacious, and in the breeding season utter the well known notes, "Ah Bob White," the first syllable rather low, but the others loud and clear; by some these notes are thought to resemble "more wet," and are therefore regarded as omens of rainy weather. The eggs are 10 to 18, pure white; the young run about as soon as hatched, but follow the old birds till spring, when they acquire their full plumage, pair, and breed; only one brood raised in a season. They rest on the ground at night, arranged in a circle with their heads outward, so that each can fly off in a straight line, if alarmed, without interfering with others; they are easily caught in snares, traps or driven into nets; they are difficult to raise from the egg, chiefly on account of the impossibility of obtaining the insects on which the young feed, but adults fatten well in captivity, eating grain, seeds, and berries; the flesh toward autumn is fat, juicy, and tender, white and highly esteemed; many perish from cold and hunger and from being imprisoned under the snow during severe winters. There is great confusion about the name of this bird; it is called quail in the northern states, but in the middle and southern partridge; where the former name prevails the ruffed grouse is called partridge, and where the latter this grouse is styled pheasant; as neither the name of quail, partridge, nor pheasant is properly given to any American bird, Mr. Baird proposes to call this species Bob White, and the *other* mountain grouse.—The genus *lophortyx* (Bonap.) has a crest of about half a dozen lengthened feathers, the shafts in the same vertical plane and the recurved webs overlapping each other; the bill weak; tail lengthened and graduated, of 12 stiff feathers, and nearly as long as the wings. Here belongs the beautiful California quail (*L. Californicus*, Bonap.), about 9½ inches long, with back and wings olivaceous brown, the secondaries and tertiaries edged with brown, breast and neck above plumbeous, the imbricated feathers on the latter with an edge and middle stripe of black; top of head brown, and crest black; throat black edged with white. This takes the place of the Bob White in California and Oregon.—The genus *callipepla* (Wagler) resembles the last, but has the crest of broad, short, soft, and depressed feathers. The scaly or blue quail (*C. squamata*, Gray) is 9½ inches long; the general color is plumbeous gray, whitish below; the feathers of the neck, upper back, and lower parts edged with black, producing the effect of imbricated scales; it is found in Texas. In this genus Gray *places* the plumed quail (*C. picta*, Gould), for which Mr. Baird has established the genus *oreortyx*; it is about 10½ inches long, with stout bill, crest of two straight feathers, and short broad tail; the general color is olivaceous brown, tinged above with rufous, and anterior part of the body grayish plumbeous; throat orange chestnut; posterior half of body beneath white, with chestnut brown central patch. It is found on the mountain ranges of California and Oregon, toward the coast. The genus *cyrtonyx* (Gould) has a very stout and robust bill, and the head with a broad soft crest of feathers; the tail is very short and of soft feathers; wings long and broad, the coverts and tertials concealing the quills; feet strong, toes short, and claws long. Massena's quail (*C. Massena*, Gould) is about 9 inches long, having the head riped with white, black, and lead color; olor black; feathers above streaked centrally ith whitish; wings with two series of round- d black spots, and lower parts and sides with ound white spots on a plumbeous ground. It found on the upper Rio Grande.—The Euro- ean quail belongs to the genus *coturnix* (Möhr.) f the partridge sub-family; in this the bill is hort, elevated at the base and arched to the ob- use tip; wings moderate, with the 2d to the th quills the longest; tail very short, pendant, nd mostly hidden by the coverts. There are bout 20 species, scattered over Europe, Asia, nd Australia, migrating in large flocks to arm regions in winter; some prefer cultivat- d districts, among tufts of grass, others rocky laces, and others elevated table lands; the food nd habits are as in other partridges. The Eu- opean quail (*C. communis*, Bonn.) is 8 inches ong, with an alar extent of 14; the upper arts are variegated with reddish, gray, and rownish black, with whitish longitudinal treaks; throat of male dark brown, and a ouble interrupted black band on the fore eck; throat of female yellowish gray; head ompletely feathered, with a white streak over he eyes. It is abundant in southern Europe, ndia, and N. Africa; it was well known to he ancients, who employed it as a fighting ird for their amusement; if the quails which erved as food for the Israelites in the desert were birds, and not locusts (as some maintain), hey probably belonged to this species. The otes of the male, especially in moonlight ights in summer, are very clear and pleasing, nd have acquired for it the specific name of *dactylisonans*. The Chinese quail (*C. Chinensis*, Edw.) is a smaller species, used in the East Indies as a fighting bird, and also for the singular purpose of warming their owners' hands in winter.—The *turnicinæ* or bush quails of the old world have a moderate and usually straight bill, short wings, and tail almost concealed by the dorsal feathers; tarsi strong; toes usually 3, long, and free at the base. In the genus *turnix* (Bonn.) the bill is curved, the tertials shorter than the primaries, and the 1st, 2d, and 3d quills equal and longest. There are more than 20 species of small size, found in southern Europe, India and its islands, Africa, Madagascar, and Australia; they frequent open places near rivers, keeping near the ground when flying, and running rapidly among the grasses; the eggs are usually 4. The *T. pugnax* (Lath.) of Java has the body varied with reddish, black, and white, beneath streaked with white and black, and throat black.

QUAKERS. See Friends, and also appendix to this volume.

QUAKING GRASS (*briza*), a genus of ornamental grasses of little agricultural value, but esteemed in gardens on account of their elegant spikelets, which, many-flowered, ovate or heart-shaped, flattish, tumid, the florets closely imbricated, are suspended on delicate pedicels and are easily agitated by the wind. The most conspicuous is the *B. maxima*, a native of Europe, very handsome and much cultivated; it is an annual, with softish, light green leaves, and numerous large and many-flowered spikes. Another species is the *B. media*, a perennial, with slender, tall stalks, darker green leaves, and many small, purplish spikelets, which hang in a graceful nodding manner. It occurs sparingly in pastures of Pennsylvania, and is not uncommon in the rocky lands near Salem, Mass. Other species are known, but these are the principal introduced into floriculture.

QUARANTINE (It. *quarantina*, Fr. *quarantaine*, a space of 40 days), a police regulation for the exclusion of contagious diseases from a city or state. Quarantines of a partial character were used in the maritime towns of Italy in the 15th century as a means of preventing the importation of the plague. In 1720, when the same disease ravaged Marseilles, the French government established a rigorous quarantine, and the usage is now general in all commercial countries. The introduction from foreign ports of yellow fever, cholera, the small pox, and other epidemics, is thus resisted by detaining ships, passengers, and goods at the frontiers, without communication with the people, until they are believed to be no longer capable of communicating the disease. The period of such detention varies according to circumstances and special laws, and by no means extends in all cases to the original 40 days from which the name of the regulation is derived.

QUARLES, Francis, an English poet and prose writer, born at Stewards, Essex, in 1592, died Sept. 8, 1644. He was educated at Christ's college, Cambridge, studied law at Lincoln's Inn, was cup-bearer for a while to the queen of Bohemia, and in 1621 went to Dublin, where he became secretary to Bishop Usher. Returning to England after several years' absence, he was appointed chronologer to the city of London, and devoted himself to literary labors until the revolution plunged him into difficulties from which he never recovered. His best known writings are his "Divine Emblems" (1635) and "Enchiridion" (1641). The former, imitated from the *Pia Desideria* of the Jesuit Herman Hugo, consists of symbolical pictures with short moral lessons in verse; the latter is a collection of brief essays and aphorisms, in vigorous and occasionally eloquent language. Among his poetical works are: "Feast for Worms, or the History of Jonah;" "Argalus and Parthenia;" "Quintessence of Meditation;" "History of Queen Esther;" an "Alphabet of Elegies," in memory of his friend Archdeacon Aylmer; "Hieroglyphics;" "The Virgin Widow," a comedy; "The Shepherd's Oracles;" "The School of the Heart," &c. In most of these works he evinces strength of thought and considerable wit, but in his excessive eagerness for effect he frequently becomes absurd and grotesque. His "Enchiridion" has been republished in Smith's "Library of Old Authors;" the "School of the Heart" and "Hieroglyphics" were reprinted in London in 1858, and the "Emblems" in 1859.—JOHN, son of the preceding, born in Essex in 1624, died of the plague in London in 1665. He was educated at Oxford, where he assisted in defending the town against the parliamentarians, was afterward a captain of the royal forces, and retiring to London after the king's final overthrow commenced author for a living. He wrote "Regale Lectum Miseriæ, or a Kingly Bed of Misery;" "England's Sonnets;" "Fons Lachrymarum, or a Fountain of Tears;" a continuation of the "History of Argalus and Parthenia;" "Divine Meditations," and other works in verse and prose. Some of his poetry is well worth preserving, though inferior to his father's in originality.

QUARRY, an open excavation made for obtaining rocks, as granite, sandstone, marble, limestone, and slates; so named from the fact that the stones are usually squared (old Fr. *quarré*) for their use in building.

QUART, a measure of capacity, the fourth part of a gallon. (See GALLON.)

QUARTZ, the most abundant of all minerals, existing as a constituent of many rocks, as the granitic, the micaceous and silicious slates, composing of itself the rock known as quartzite or quartz rock, and some of the sandstones and pure sand, forming the chief portion of most mineral veins, and found interspersed in crystals and crystalline fragments throughout many rocks, and especially in their fissures and cavities. In composition it is silica in that state in which it is insoluble in strong potash solutions. Often the mineral is uncontaminated with any foreign intermixture, and then appears in clear transparent crystals like glass or ice. The presence of a little oxide of manganese gives to these a violet tinge, and they are then known as amethyst. Other impurities which variously affect the appearance and properties of quartz, even in the small quantities in which they enter into its composition, are oxide of iron, alumina, oxide of nickel, &c. Through all its varieties quartz is distinguished by the same chemical properties and degree of hardness. This, which enables the mineral to scratch glass and to give fire when struck with steel, is represented by 7 of the scale of hardness. Its specific gravity is 2.5 to 2.8. Its lustre is vitreous, its colors various according to the impurities present, and its fracture conchoidal. It is fusible only at the intense heat of the oxy-hydrogen blowpipe, and of the furnaces lately invented by M. H. St. Claire Deville; but it is readily fluxed with soda or lime. The quartz glass obtained by Deville, amounting to 30 grammes, possessed a density of only 2.2, or about ¼ less than that of the crystallized quartz from which it was melted. The colorless transparent crystals impress circular polarization upon a ray of plane-polarized light. They exhibit double refraction when the object is observed through two faces which are not parallel to each other. Milk-white varieties often give a phosphorescent light when rubbed together in the dark. The primary form of the crystal, which is very rarely seen, is a rhomboid. The common form is a hexagonal prism terminated by hexagonal pyramids. The crystals occur in groups of great beauty and of all sizes up to single crystals of several hundred pounds' weight. In the museum of the university at Naples is a group of nearly half a ton weight. In Milan is a crystal 8¼ feet long and 5½ in circumference, estimated to weigh 870 lbs. A crystal in the museum of natural history in Paris is 3 feet in diameter and the same in length, and weighs 800 lbs. Occasionally immense quantities of crystals are found collected together in cavities in the rocks and in caves, loose and incrusting the walls. Such a collection, discovered at Zinken more than a century ago, produced 1,000 cwt. of rock crystal, which at that period, when the article was more highly valued than at the present time, brought $300,000. In the United States some rich deposits have been met with in the Ellenville lead mine, Ulster co., N. Y., and in some of the southern gold mines; and large groups of fine crystals have been found in Moose mountain, N. H., and in Waterbury, Vt. Little Falls on the Mohawk in New York is a famous locality for the purest transparent crystals of complete forms, and they are met with in other places also in the same region, occurring in the cavities of the calciferous sand rock, which overlies the Potsdam sandstone. Trenton Falls also furnishes perfect transparent crystals, which are sometimes 5 inches long and contain drops of water. These are occasionally recognized in quartz crystals of various localities. In St. Lawrence and Jefferson cos., N. Y., in the deposits of iron ore, quartz crystals are found of dodecahedral forms. In Orange co., 4 m. E. of Warwick, they occur in the primary form. Many of the varieties of quartz are known by other names, under which they have been particularly described in this work. (See AMETHYST, AGATE, CARNELIAN, CATS' EYE, CHALCEDONY, FLINT, GEODE, JASPER, &c.)—Clear crystalline quartz, called rock crystal, was in former times esteemed as a beautiful material for ornamental objects. It was cut into vases, cups, lustres, &c., many of which are still preserved as curiosities. In the museum of the Louvre are great numbers of them, some belonging to the times of the ancient Greeks and Romans, but more generally of the period of the middle ages. The perfection to which the manufacture of glass and pastes has been brought and the cheapness of these materials have almost completely taken away the value of rock crystal, which requires a great amount of labor in its cutting and polishing, and after all is not really superior to the artificial products. Some use is however still made of it, as for buttons, seals, breast pins, &c. It is procured from Madagascar, Switzerland, and Brazil. In Switzerland quartz veins which occasionally yield rich cavities of crystals are regularly mined for this product. From Madagascar large clear masses are received which sell for from $1 to $10 per pound. When cut and set by the jewellers the stone is commonly sold as white topaz, and sometimes as "California diamonds." In the arts lenses of pure quartz are used for object glasses of astronomical telescopes; and by the French lenses are cut to give the double image by refraction, and set in telescopes for estimating distances by means of this property. Pure quartz is largely employed in the manufacture of glass, and is commonly obtained for this purpose in the form of sand. Quartz rock of the metamorphic group is sometimes found of a granular structure and crumbly consistency, and of great purity, well adapted for this application. (See Glass.) Varieties of quartz of a cellular texture and great tenacity are used for millstones, the roughness and hardness of their surface and sharpness of the edges of the cells giving them a powerful grinding capacity combined with great durability. (See Buhrstone.) Sandstones and conglomerates composed of quartz pebbles are refractory fire stones, and are used for the hearths and inner walls of furnaces.

QUASSIA, the wood of the *simaruba excelsa* (De Cand.), *quassia excelsa* (Willd.), or *picraena excelsa* (Lindley), a lofty tree growing in Jamaica and the Caribbean islands, where it is known as the bitter ash. Quassia was originally obtained in Surinam from the *quassia amara*, a small branching tree or shrub, all parts of which are excessively bitter, and of which the root bark and wood were formerly officinal for their tonic properties. The substance was brought into notice as a medicine about the middle of the last century by a negro of Surinam named Quassi, and being taken thence to Stockholm in 1756 it soon became a very popular medicine in Europe. But as the original source of supply failed, recourse was had to the similar product of the *quassia excelsa*, with which the demand has since been met. It is received in sticks of an inch to nearly a foot in diameter, which are pieces of the branches and stem; and in the shops these are kept split in small pieces or rasped. The wood has an intensely bitter taste, and imparts its properties to water and alcohol; and of late years drinking cups have been made of it for the use of invalids. Its decoction yields a peculiar bitter crystallizable principle, named quassine. The properties of quassia are those of the simple bitters, and as a medicine it is adapted to cases of dyspepsia and the debilitated state of the digestive organs which sometimes succeeds acute disease. The decoction was formerly used in England by some of the brewers as a substitute for hops, but this is now prohibited under severe penalties. When sweetened it makes an efficacious fly water.

QUATRE BRAS. See Waterloo.

QUATREFAGES, Jean Louis Armand de, a French naturalist, born in Valleraugue, department of Gard, Feb. 6, 1810. He was graduated doctor in medicine and science at Strasburg in 1829, published papers *Sur les aérolithes* (1830), and *De l'extroversion de la vessie* (1832), and, while assistant professor of chemistry in the medical faculty at Strasburg, wrote extensively for scientific periodicals. In 1839 he was appointed to the professorship of zoology at Toulouse, but soon resigned it to repair to Paris, where he found great facilities for study. Among his publications, most of which have appeared in the *Annales des sciences naturelles*, are: *Considérations sur les caractères zoologiques des rongeurs* (4to., 1840); *De l'organisation des animaux sans vertèbres des côtes de la Manche* (1844); *Recherches sur le système nerveux, l'embryogénie, les organes des sens et la circulation des annélides* (1844-'50); *Sur l'histoire naturelle des tarets* (1848-'9); and *Sur les affinités et les analogies des lombrics et des sangsues* (1852). He published in the *Revue des deux mondes*, under the title of *Souvenirs d'un naturaliste*, a narrative of scientific travels along the shores of the Atlantic and the Mediterranean. Part of these *Souvenirs* have been printed separately (2 vols. 12mo., 1854; English translation, 2 vols., London, 1857). In 1850 he became professor of natural history in the *lycée Napoléon*, in 1852 member of the academy of sciences, and in 1855 professor of anatomy and ethnology in the museum of natural history.

QUATREMÈRE, Étienne Marc, a French orientalist, born in Paris, July 12, 1782, died Sept. 18, 1857. He was a pupil of Sylvestre de Sacy and Chézy, acquired a knowledge of the Hebrew, Chaldaic, Coptic, Syriac, Persian, Turkish, and Armenian languages, in 1807 received a subordinate office in the MS. department of the imperial library, in 1809 was appointed professor of Greek in the faculty of letters at Rouen, in 1815 succeeded Laporte-Dutheil as a member of the academy of inscriptions, in 1819 was called to the college of France to teach Hebrew, Chaldaic, and Syriac, and in 1827 became professor of Persian at the school of the living eastern languages. He left many valuable works. To him is mainly owing the identification of the modern Coptic with the language of the ancient Egyptians, which gave the first clue to the interpretation of the hieroglyphics. His library, one of the most complete in oriental literature ever collected, was bought by the king of Bavaria and removed to Munich.

QUATREMÈRE DE QUINCY, Antoine Chrysostome, a French archæologist and writer on æsthetics, second cousin of the preceding, born in Paris in 1755, died in 1849. In 1785 a paper *Sur l'architecture égyptienne* secured for him a prize from the academy of inscriptions; he was then engaged as a contributor to the *Encyclopédie méthodique*, for which he wrote a "Dictionary of Architecture" (3 vols. 4to., 1795-1825). On the breaking out of the French revolution he sided with the moderate party, and was appointed a member of the commune of Paris, and elected a deputy to the legislative assembly in 1791. Imprisoned for 18 months during the reign of terror, he owed his life to the overthrow of Robespierre, became one of the council of 500 in 1797, and was suspected of being an active royalist. On the 18th Fructidor his name was placed on the proscribed list by the republican directors; but he avoided transportation by concealment. He reappeared under the consulate, became first a member and then chief secretary of the municipal council of the Seine, and under the Bourbons was appointed superintendent of public monuments in 1815, and in 1818 professor of archæology in the royal library. In 1820 he took his seat in the chamber of deputies, but he soon abandoned politics. He had early been admitted to the academy of inscriptions, and afterward to that of fine arts, of which from 1816 to 1839 he was secretary-general. Among his voluminous works are: *Le Jupiter Olympien* (fol., Paris, 1814), a restoration of the great work of Phidias; *De l'imitation dans les beaux arts* (1823; English translation by J. C. Kent, 8vo., 1837); and *Histoire de la vie et des ouvrages de Raphaël* (1824).

QUEBEC, a fortified city and port of entry of Canada East, now (1861) actual capital of Canada and the residence of the governor-general of the British possessions in North America, situated on the N. W. bank of the river St. Lawrence, at its confluence with the St. Charles, about 360 m. from the gulf of St. Lawrence, and 180 m. N. E. from Montreal, in lat. 46° 49′ 12″ N., long. 71° 16′ W.; pop. in 1861, exclusive of the suburbs, 51,134, nearly ⅔ of whom are of French extraction, and ⅘ Roman Catholics. The French is the prevailing language here as in Lower Canada generally. Quebec is built upon the slope of an elevated promontory or table land, which forms the left bank of the St. Lawrence for about 8 m., and has on that side an almost precipitous face, but declines more gradually to the St. Charles. This promontory is called Cape Diamond, from the numerous quartz crystals found in its rocks. The city is divided into the upper and lower towns. The upper town extends along the table land already mentioned, and inclines toward the river St. Charles, in a N. W. direction. It is surrounded by a wall 2¾ m. in circuit, mounted with cannon and having 5 gates. Here are situated the great hotels, the finest stores, the theatre, the parliament house, the bureaux of the officers of state, the court house, the city hall, &c. It is the quarter of fashion, and the residence of capitalists and officers of government. From its ramparts and terraces, the views of the lower town, the rivers, the island of Orleans, Point Levi, and the adjacent country are among the finest in America. To the W. of the walls, and extending along the heights, lie the populous faubourgs of St. Louis and St. John, reaching far beyond the official limits of the city, in lines of elegant country seats, surrounded by trees and gardens. At some distance from the barriers of these faubourgs two commemorative columns rise on the celebrated plains of Abraham; one, of stone, surmounted by a fasciculus of arms, is dedicated to the memory of Gen. Wolfe, who fell at this point; the other, of bronze, is consecrated to the memory of the soldiers who shed their blood in the second battle on the plains of Abraham. The citadel, which is built upon the culminating point of the cape and commands the whole city, is 345 feet above the level of the river. It covers about 40 acres, and is regarded as the Gibraltar of America. The approach from the west, in the direction of the plains of Abraham, is defended by 4 martello towers 500 or 600 rods apart, and placed about ½ of a mile from the walls of the city. The lower town lies at the foot of the cliff along the banks of the rivers, upon an alluvial soil, and is bordered with wooden quays. This is the seat of the principal business of the city, and here are to be found the great commercial houses, banks, insurance offices, the exchange, the custom house, &c. During the season of navigation, this quarter of the city presents a scene of great activity. The docks for the river vessels, the breweries, distilleries, foundries, gas works, tanneries, soap manufactories, and ship yards are upon the banks of the St. Charles, in the faubourg of St. Roch. This large quarter, though inhabited mainly by the working population, has some fine streets and elegant stores. The ascent from the lower to the upper town is made by flights of steps and by steep winding streets.—Quebec has many fine buildings. The custom house, on the bank of the river, is an imposing Doric edifice with a dome and a façade of noble columns, approached by a long flight of steps. Quebec is the seat of a Roman Catholic archbishop and of an Anglican bishop. The interior of the Catholic cathedral, the chancel of which is copied from the apsis of St. Peter's at Rome, is much admired; the walls are adorned with paintings, one of which is a superb Vandyke. The chapel of the seminary, near the church, has the best collection of religious paintings in America. The Protestant cathedral, a plain gray edifice surmounted by a tall spire, stands in the centre of a large square, enclosed with an iron fence. To the S. E. is the parade ground, a central point, adorned with a fine fountain; and to the S. of this is the Durham terrace, which travellers pronounce the finest point of view in the world. The garden of the fortress, another fine promenade, has an obelisk erected in 1828 to the memory of the two heroes, Wolfe and Montcalm. Montcalm's remains are buried in the chapel of the convent of the Ursulines, but the body of Wolfe was conveyed to Westminster abbey. The Chalmers church, the Wesleyan church (in the flamboyant style), and the chapel of the gray sisters, are good specimens of Gothic church architecture. The marine hospital, built after the model of the temple of the Muses on the banks of the Ilissus, the archbishop's palace, the university of Laval, the theatre, and the city hall are also worthy of notice.—Quebec has several scientific and literary societies and institutions. The literary and historical society, founded in 1824, has a good library, and a collection of records of the realm in 80 or 90 folio volumes, with many historical manuscripts; but it suffered a severe loss in the burning of a part of its museum and library in the fire of Feb. 1854. There are beside this several institutes, reading rooms, and library associations. The merchants' exchange has a large reading room, well supplied with newspapers and periodicals. The legislative library has over 60,000 volumes, and a valuable collection of historical manuscripts. The educational institutions are numerous, and highly creditable to the city. The university of Laval, opened in 1854 in connection with the seminary of Quebec, an old theological institution founded in 1663 by the first Catholic bishop, Mgr. Laval, has buildings valued at $400,000, a library of 20,000 volumes, a cabinet of physical science, an anatomical museum, &c. The law department has 6 professors, and the medical 6. The faculties of arts and theology, not yet fully organized, are to have 16 chairs. The high school of Quebec (Protestant) has 6 professors, 200 students, and a library of 1,200 volumes. The college of St. Michel has 5 lay Catholic professors and 142 students; and the college of Notre Dame de la Victoire, conducted by the order of Christian Brothers, has 13 professors and 345 students. There are 5 convents with 64 teachers and over 1,900 female pupils, and 23 academies and private schools. There are 8 newspapers published in Quebec, 2 of which are daily, 5 tri-weekly, and 1 semi-weekly; there is also a monthly literary journal. The principal benevolent institutions are the lunatic asylum, the marine hospital, and the Hôtel Dieu. The city is supplied with an abundance of pure water from Lake St. Charles, just above the fall of Lorette, 9 m. distant.—The St. Lawrence is about ¾ of a mile (1,314 yards) wide opposite Cape Diamond, but the mouth of the St. Charles forms with it a basin nearly 4 m. long and more than 1½ m. wide. The depth of the water is about 28 fathoms. The ordinary tide is 17 or 18 feet at new and full moon; but the spring tides attain a height of 23 or 24 feet. The harbor is safe and commodious, and the largest vessels can lie at the wharfs. The steamship Great Eastern during the summer of 1861 visited Quebec, and lay at anchor at the foot of the citadel. In the latter part of December the river is closed by ice, and navigation ceases till the latter part of April, when the ice usually disappears very suddenly; steamers arrive from Montreal about April 25, and sea-going vessels about a week later. There is a regular line of steamers plying between Quebec and Gaspé and the provinces of the gulf, and two lines of royal mail steamers between the city and British ports. There is also a steam ferry connecting the city with the terminus of the railroad S. to Point Levi and Richmond, which is a branch of the grand trunk line. Telegraphic lines also connect it with the principal cities of Canada, the gulf colonies, and the United States.—Quebec is a free port. From the annual official "Tables of the Trade and Navigation of the Province of Canada," we compile the following statistics of its commerce for 1858, 1859, and 1860:

Arrivals.				Departures.			
Years.	Ships.	Tons.	Men.	Years.	Ships.	Tons.	Men.
1858..	[illegible]	[illegible]	[illegible]	1858..	[illegible]	[illegible]	[illegible]
1859..	970	[illegible]	[illegible]	1859..	[illegible]	[illegible]	[illegible]
1860..	1,252	[illegible]	[illegible]	1860..	[illegible]	[illegible]	[illegible]

Of the arrivals in 1860, 836 vessels came from Great Britain, 176 from the English colonies, 24 from the United States, and 206 from other foreign countries; 548 brought cargoes, and 704 were in ballast. Of the departures, 1,166 were destined to the British islands, 144 to English colonies, 4 to the United States, and 9 to other foreign countries. Beside this movement by sea, there came from the United States in 1860, by way of the lakes and river, 3 steamboats and 22 barks, with a tonnage of about 4,119; and the departures by the same interior route were 2 steamboats and 27 barks, tonnage 5,427. Quebec is the principal centre of maritime commerce in British North America, and one of the largest timber and lumber ports on the American continent. But while its exports are larger than those of any other city in Canada, its imports are below those of Montreal and Toronto. The following are the imports and exports of the last 4 years:

	Imports.	Exports.
1857	[illegible]	[illegible]
1858	[illegible]	[illegible]
1859	[illegible]	[illegible]
1860	[illegible]	[illegible]

The principal articles of importation are woollen, cotton, and silk goods, iron, hardware, coal, groceries, and salt. More than ⅘ of the whole amount of imports comes from Great Britain; the goods brought from the United States amounted in 1860 to $687,567. The exports consist principally of ships, lumber, and grain. The ships built at Quebec are renowned for their beauty, solidity, and sailing qualities. The number and tonnage of vessels propelled by sails and steam, built at Quebec for the last 4 years, are as follows:

	Ships.	Tons.
In 1857	64	[illegible]
" 1858	[illegible]	[illegible]
" 1859	48	[illegible]
" 1860	[illegible]	[illegible]

In 1860 the amount of lumber exported was 596,995 tons, of the following kinds and values: white pine, $2,468,736; red pine, $507,803; oak, $271,490; elm, $206,607, &c. The average exportation of lumber during the last 5 years has been about 500,000 tons. The other principal exports were: deals, $1,591,149; standard staves, $310,600; masts, $73,420; laths, $36,264; spars, $24,006; flour, $298,724; wheat, $30,199; coin and bullion, $59,-

178. The timber, deals, and cabinet work are sent mainly to Great Britain, and the breadstuffs to the English colonies of North America. There are some manufactories of distilled and fermented liquors, leather, tobacco, soap, &c. The city has two banks of circulation, with a paid-up capital of $1,682,863, and authorized $4,000,000; circulation, $878,828. It has also branches of 5 foreign banks, and 16 insurance offices.—The municipal government of the city consists of a mayor and 24 councillors. It has one representative in the legislative council, and 8 deputies in the house of assembly. Quebec is also the county seat of the county of Quebec; area, 16,440 sq. m.; pop. 27,951, aside from that of the city.—Quebec was founded by Samuel Champlain in 1608. It was taken by the English in 1629, and restored to France by the treaty of 1632. In 1636 it had 100 inhabitants. It was the colony of a concessionary company, who did not fulfil their promises to the settlers, and hence its growth was slow. The magistrate, named by the company, was called a syndic, and had powers similar to those of a mayor. The king, dissatisfied with the management of the company, took the colony into his own hands, and in 1663 appointed a governor, and created the sovereign council of Quebec, who were charged with its government. During the war of the league of Augsburg, the neighboring English colonies made an unsuccessful maritime expedition against it (1690). In 1711 the attempt was renewed, with no better success. The first attempt at erecting stone fortifications was made after the first of these attacks, the place having been previously protected only by palisades. In 1734 it had, including its suburbs, only 4,603 inhabitants. In 1759, during the 7 years' war, the English Gen. James Wolfe attacked the city and bombarded it. On Sept. 13, 1759, took place the first battle of the plains of Abraham, in which both the contending generals fell, and England gained at one blow an American empire. On Sept. 18 Quebec capitulated after a siege of 69 days. The French attempted its recapture, and in the following spring the 2d battle of the plains of Abraham was fought, and victory sided with the French colonists; but at the treaty of peace in 1763 Louis XV. ceded the whole of New France to the English. Quebec rose slowly from its ashes, though its commerce increased. In 1764 the first newspaper, the "Quebec Gazette," published in two languages, made its appearance. In 1775 the city had only 5,000 inhabitants. In 1776 a small American force under Gen. Montgomery attempted its capture, but failed, with the loss of about 700 men and their commander. In 1792, the year of the inauguration of the representative system in Canada, the first Lower Canadian parliament was convoked at Quebec, and the city remained the seat of government for the lower province till the union of the Canadas in 1840. During this period its growth was steady and mod-
erately rapid; in 1844 its popul

been killed or driven into exile. Capital, Q
da; pop. about 2,000.

QUEEN (Goth. *queins*, *quens*, a wom
wife; Sax. *cwen*, *quena;* Gr. *γυνή*, a w
the wife of a king, or a woman who is
sovereign of a kingdom. In the former c
city she is regarded in most countries as a
son of dignity only inferior to that of her
band, and possesses all the privileges enjoy
a *feme sole*. Thus in England she can re
grants from or make them to her husband
purchase or convey land without *his* co
rence, can sue and be sued alone, and di
of her property by will. She has a sep
household and separate courts and offic
exempted from paying tolls and amercements
and has other extraordinary privileges; and
compass or imagine her death, or to violate
defile her person, even with her consent
treason. If accused of treason *herself*, s
tried by the peers of parliament. She is
entitled to be crowned with full regal sole
ties. In other respects she is on a footing
equality with the subjects of her husband
accordance with the maxim of the Roman la

esta legibus soluta non est. As a sovereign ess—a signification not originally compre- ed in the term queen—she possesses all attributes of a king. In France, where by Salic law a female cannot succeed to the ne, the mother of a sovereign has some- s exercised royal authority during the mi- y of her son, in which case she has been d the queen regent. The queen dowager e widow of a king, and as such enjoys most he privileges accorded to her during the ime of her husband. In England she does lose her rank, although she marry with a nmoner; but no one can contract a marriage h her without a special license from the reign. When the queen dowager is mother he sovereign, she is commonly called the en mother.

UEEN ANNE, an E. co. of Md., bordered y Delaware, W. by Chesapeake bay, and W. by Chester river, and drained by a num- of creeks, among which Tuckahoe is the gest; area, 400 sq. m.; pop. in 1860, 15,961, whom 4,174 were slaves. It has a rolling face and fertile soil. The productions in 0 were 697,159 bushels of Indian corn, ,003 of wheat, 59,885 of oats, 9,614 of rye, 730 lbs. of wool, and 97,183 of butter. There re 8 grist mills, 3 saw mills, 2 newspaper ces, 23 churches, and 729 pupils attending lic schools. Capital, Centreville.

UEENS, a S. E. co. of N. Y., in the W. t of Long island, bordered N. by Long nd sound and S. by the Atlantic ocean; a, 410 sq. m.; pop. in 1860, 57,391. Its sur- e is somewhat hilly; much of the soil is fer- , and nearly all is highly cultivated. The res are much indented by bays and inlets, l on the S. beach there are many small nds. The productions in 1855 were 337,685 hels of Indian corn, 102,217 of wheat, 199,- of oats, 71,019 of rye, 21,224 of buckwheat, .135 of potatoes, 51,395 tons of hay, and .983 lbs. of butter. There were 24 grist s, 7 saw mills, 5 newspaper offices, 73 rches, and 17,365 pupils attending public ools. It is intersected by the Long island road, and the Flushing railroad lies wholly hin the county. Capital, North Hempstead.

UEEN'S, a middle co. of Prince Edward nd, bounded N. by the gulf of St. Lawrence d S. by Northumberland strait; area, 756 m.; pop. in 1848, 32,111. It is deeply in- ted by a number of inlets and bays, by one which, Hillsborough bay, it is nearly inter- ed. This bay affords a safe harbor for the est ships. The surface is diversified and soil very fertile. Capital, Charlottetown.

UEEN'S, a S. W. co. of Nova Scotia, bor- ed S. E. by the Atlantic ocean, and drained Broad, Mersey, and Port Medway rivers; a, 950 sq. m.; pop. in 1851, 7,256. Its coast dented by a number of bays, and the in- or contains several beautiful lakes. Its sur- e is rugged, and the soil along the streams is le. Capital, Liverpool.

QUEEN'S, a S. co. of New Brunswick; area, about 1,500 sq. m.; pop. in 1851, 10,634. It is intersected by the river St. John, and drained by several of its tributaries, of which the more important are the Salmon river, the Washadon-rock, and the Nerepis. The St. John is navigable to Fredericton, 90 m. from its mouth. The Salmon flows into Grand lake, a beautiful sheet of water about 30 m. long and from 3 to 10 m. broad. Capital, Gagetown.

QUEEN'S, a S. E. county of Ireland, province of Leinster, bounded N. by King's county, E. by Kildare, S. by Carlow and Kilkenny, and W. by Tipperary; area, 664 sq. m.; pop. in 1851, 111,623. The principal towns are Mountmellick, Mountrath, Maryborough, and Portarlington. The surface is generally undulating, rising toward the N. W. into the Slieve-Bloom mountains, the highest summit of which is 1,734 feet above the sea. The principal rivers are the Barrow and Nore; and there is only one small lake in the county. Iron and copper ore are found; and anthracite coal mines are extensively worked. With the exception of the centre of the county, where there are extensive bogs, the soil is generally fertile. Queen's county returns 3 members to parliament, 2 for the county and one for Portarlington.

QUEENSTOWN, or COVE OF CORK, a town of Ireland, county Cork, situated on the N. side of Cork harbor, 9 m. S. W. from Cork; pop. in 1851, 11,428. There are no manufactures, and the town is supported principally by the naval and military establishments in its vicinity. The harbor is excellent. The name was changed from Cove to Queenstown in honor of a visit paid by Queen Victoria in 1849.

QUÉRARD, JOSEPH MARIE, a French bibliographer, born in Rennes, Dec. 25, 1795. He was placed in a bookseller's shop at the age of 12, and afterward was employed in the same business in Paris and Vienna, where he collected the materials for his first bibliographical work, *La France littéraire* (10 vols. 8vo., 1826–'42). This with its complementary publication, *La littérature Française contemporaine* (1837–'44), comprised a list of works printed in French since 1700, with biographical notices of the authors. So far, however, did the continuation promise to exceed its projected size, that the publisher took it by legal process, unfinished, out of Quérard's hands, and it was completed by others; and Quérard, mulcted in damages, passed several months in prison. He has since published various works, and projected an *Encyclopédie du bibliothécaire*, upon a very extensive plan. His most curious work is *Les supercheries littéraires dévoilées* (5 vols., 1845–'59), exposing the impostures, apocryphal authors, and plagiarisms in modern French literature.

QUERCITRON, the bark of the black oak, *quercus tinctoria*, used as a dye stuff. The black outer portion of the bark being removed, the inner portion is found to contain a coloring principle which stains the saliva yellow when the bark is chewed; this is extracted by boiling water, giving to it a brownish yellow color, which is deepened by alkalies and brightened by acids. The bark is largely employed in the United States as a dye, and it is also reduced to a coarse powder and shipped to Europe in great quantities for the same use, particularly in calico printing. When its decoction has been deprived of tannin by means of glue, a fine yellow color is obtained upon fabrics mordanted with alum, and various shades of olive with iron mordants. The coloring principle is called quercitrine, or from its acid reaction quercitric acid. Black oak bark is used for tanning also, but the yellow color is an objection to this use. Its astringent and tonic properties have led to its use in medicine, but white oak bark, having similar medical properties without the color, is preferred. On account of its tendency to irritate the bowels it is generally applied externally as a bath rather than internally, and is prescribed, particularly for children, in cases of cholera infantum, scrofula, intermittent fevers, &c.

QUERETARO, a S. state of Mexico, bounded N. by the state of San Luis Potosi, E. and S. by Mexico, and W. by Michoacan and Guanajuato; area, 1,820 sq. m.; pop. 180,000. It occupies a part of the plateau of the Cordillera, and is traversed by numerous mountain spurs; but though its general character is rugged, it contains much fertile land. The rivers are all small, and the Tula and Rio de Montezuma, which flow on the eastern frontier, are the only streams that deserve notice. Gold, silver, copper, quicksilver, tin, lead, and antimony are all found. Grain is extensively cultivated, and considerable numbers of cattle are reared. Woollen and cotton goods are manufactured, from materials produced within the state.—QUERETARO, the capital, is situated on a plateau 6,365 feet above the level of the sea, 110 m. N. W. from Mexico; pop. 47,570. It occupies the sides and summits of several hills. The streets are well laid out, the houses regular, and the city is considered next in rank to Mexico. The principal church is magnificently decorated. The city is supplied with water by an aqueduct 2 m. long, which crosses a plain upon arches 90 feet high, and in connection with a tunnel brings the water a distance of 6 m. The manufactures consist chiefly of woollen and cotton goods and leather. In 1848 the Mexican congress ratified the peace between Mexico and the United States at Queretaro.

QUERINI, ANGELO MARIA, an Italian scholar, born in Venice in 1680, died in 1755. He was of a patrician family, was educated at the college of the Jesuits in Brescia, and at the age of 17 became a Benedictine monk in Florence. In 1710 he set out on a tour through Europe, and travelled 4 years in France, England, Holland, and Germany. In 1721 he was made archbishop of Corfu, and in 1728 was transferred to the see of Brescia, created cardinal, and soon after made librarian of the Vatican. The remainder of his life was spent in Brescia. Voltaire dedicated to him his "Semiramis."

QUESADA. See XIMENES DE QUESADA.

QUESNAY, FRANÇOIS, a French physician and political economist, founder of the sect of the physiocrats, born near Montfort-l'Amaury, department of Seine-et-Oise, June 4, 1694, died in Versailles, Dec. 16, 1774. Although the son of an advocate, his early education was entirely neglected; but having a strong love of study, he found means to acquire a knowledge of Latin and Greek, and at an early age began the study of medicine. He first established himself in Mantes, from which place he returned to Paris about 1729 or 1730. There he became physician to Mme. d'Étioles, afterward the marchioness de Pompadour. In 1[illegible] he was made surgeon in ordinary to the king, then secretary of the royal academy of surgery, and in 1744 consulting physician to the king. He wrote a number of medical works, and finally devoted his attention to political economy. (See AGRICULTURAL SYSTEM, vol. i. p. 224, and POLITICAL ECONOMY, vol. xiii. p. 448.)

QUÉTELET, LAMBERT ADOLPHE JACQUES, a Belgian astronomer, statistician, and moral philosopher, born in Ghent, Feb. 22, 17[illegible]. When scarcely 18 years old he was appointed professor of mathematics in his native town, and 5 years later at the Athenæum in Brussels. In 1824 the king of the Netherlands sent him to Paris to complete his astronomical studies; and on his return home in 1826, he was charged with superintending the building of an observatory, receiving at the same time the directorship of that institution, which he still holds. Between 1827 and 1829 he visited England, Scotland, Germany, Switzerland, and Italy. He is now perpetual secretary of the academy of sciences of Belgium, and corresponding member of the French institute. He has published *Astronomie élémentaire* (1826); *Recherches statistiques sur le royaume des Pays Bas* (1830); *Recherches sur la réproduction et la mortalité, et sur la population de la Belgique* (1832); *Statistique criminelle de la Belgique* (1832); *De l'influence des saisons sur la mortalité aux différents âges* (1838); *Sur la théorie des probabilités appliquées aux sciences morales et politiques* (1846); *Du système social et des lois qui le régissent* (1848); *Sur la statistique morale et les principes qui doivent en former la base* (1848), and since 1838 the *Annuaire de l'observatoire de Bruxelles*.

QUETZALCOATL. See HUASTECAS.

QUEVEDO Y VILLEGAS, FRANCISCO GOMEZ DE, a Spanish author, born in Madrid in 1580, died at Villanueva de los Infantes, Sept. 8, 1645. He was educated at the university of Alcala, and took a degree in theology at the age of 15. Having killed a nobleman in a duel for insulting a lady, he fled to Sicily, where the viceroy, the duke of Ossuna, gave him honorable employment, and on his removal to Naples made him minister of finance. He several times visited Madrid on diplomatic business, was pardoned for his former offence and received a pension. He was concerned in the conspiracy of the duke of Bedmar against Venice, and being in that city when the plot was discovered narrowly escaped with his life. After the disgrace of his patron (1620) he was kept a prisoner at his country seat, La Torre de Juan Abad, for 3½ years, on charge of libelling the government, but was released without trial. He published in 1631 a collection of the poetry of Luis de Leon, and a volume of "Poems by the Bachiller Francisco de la Torre," consisting of sonnets, odes, *canciones*, elegies, and eclogues, forming on the whole one of the best collections of miscellaneous poetry in the Spanish language, and being probably the work of Quevedo himself. In 1639, having made another visit to Madrid, he was seized one night at the house of a friend and thrown into a damp dungeon in a convent. His alleged offence was the composition of some satirical verses which had been laid under the king's napkin at dinner; and though it was soon discovered that another had written them, he was kept for 4 years in rigorous confinement. His papers having been twice seized by the government, the greater part of his works have never been printed. Among his published writings are: "On the Providence of God;" "God's Politics and Christ's Government," in which he endeavors to collect a complete body of political philosophy from the example of the Saviour; "On a Holy Life;" "The Militant Life of a Christian," &c. His most celebrated works are his prose satires, in which he exhibits more wit than delicacy. Of these we may mention his "History and Life of the great Sharper, Paul of Segovia" (1627); his treatise "On all Things, and many more;" "The Tale of Tales;" and "Letters of the Knight of the Forceps" (*Cartas del caballero de la Tenaza*, 1635). His *Sueños*, or "Visions," perhaps the most popular and effective of his satires, were published collectively in 1635 and translated into English by Sir Roger L'Estrange in 1708. They display a great deal of bold and original thought, but are coarse, overdrawn, and affectedly epigrammatic. A collection of Quevedo's poetry was made by Salas in 1648, and another by Aldrete in 1670, under the title of "The Spanish Parnassus, divided into its two Summits, with the Nine Castilian Muses." The best edition of his works is that of Sancha (11 vols. 8vo., Madrid, 1790–'94). A translation of the satirical works appeared at Edinburgh in 1798.

QUIBERON, a town of France, in the department of Morbihan, situated on a peninsula of the same name, which forms with several small islands a fine bay; pop. about 3,000. In 1746, during the war of the Austrian succession, the English attempted a landing here, but were repulsed with great loss. On June 27, 1795, a body of French royalists under D'Hervilly and Puisaye landed here from an English fleet, and took possession of Fort Penthièvre, by which the peninsula is defended; but they were defeated and driven into the sea by Gen. Hoche, and the prisoners massacred after capitulating.

QUICHÉS, KICHÉS, or UTLATECAS, a semi-civilized nation of Guatemala, which was allied in blood and language with the Kachiquels and Zotugils, and connected more or less intimately with all the members of the great Tzendal or Maya family. At the time of the conquest, the Quichés occupied the greater part of what is now called Los Altos, or the highlands of Guatemala, including the districts of Quiché, Totonicapam, and Quesaltenango. The traditions of the Quichés indicate that they sprang from the Toltecan stock, either as a colony or as a fragment thrown off at the time of the disruption of the Toltecan power, which had its seat in the centre of Chiapas, and of which Palenque was probably the capital. Their records, as transmitted to us by members of the royal house, who wrote them out immediately after the conquest, give a long array of kings, and imply a high antiquity for the nation. It seems that the Kachiquels and Zutugils were once embraced in the Quiché kingdom, and that their separation was the act of the king Acxopil, who had two sons, between whom he divided his power, retaining to himself the capital and surrounding regions, which preserved the name of Quiché. These three divisions, subsequently becoming hostile, were easily conquered by the Spaniards. Alvarado encountered his most vigorous resistance in Quiché, where the king, Tecum-Umam, went out to meet him, according to the chroniclers, with 232,000 men. They fought with great bravery, but musketry and cannon, and above all the terror inspired by the Spanish horse, proved too powerful for resistance with the rude means at their command. The battle lasted 6 days, the Indians fighting as they fell back with furious desperation. The king at last was slain by Alvarado, and the subjugation of the Quichés was completed.—The ruins of the city of Quiché, described by Mr. Stephens, attest the grandeur and power of this people, and give a fair support to the early accounts of their numbers. The district which they occupied is the best populated portion of Guatemala, and is almost purely Indian, the ancient language being still in general use. The people are described by M. Arthur Morelet as "an active, courageous race, whose heads never grow gray, persevering in their industry, skilful in almost every department of art, good workers in iron and the precious metals, generally well dressed, neat in person, with a firm step and independent bearing, and altogether constituting a class of citizens who only require to be better educated to rise equal to the best." Their language is regarded as a purer dialect than either the Kachiquel or Zutugil, with which it is compared by Fray Ildefonso Flores, in his *Arte de la lengua Kachiquel* (Guatemala, 1753).

QUICHUAS, one of the four great families into which the aboriginal Peruvians were divided, the others being the Aymaras (Inca), the Atacamas, and the Changos, each speaking distinct languages, but those of the Quichuas and Aymares having so many affinities as to be regarded as dialects of a common tongue. The Quichuas were the especial subjects of the Incas, and the nucleus of their empire, occupying the capital, Cuzco, and a vast extent of the surrounding country. Numerically they were the dominant race of Peru, and their language was the most widely diffused of any spoken in the empire. At this day they compose nearly three fourths of the Indian population of Peru and Bolivia. Physically they are short, with broad chests, and capable of long and severe exertion. Their complexion has not the coppery hue of the North American Indians, nor the yellow tinge of the Indians occupying the lower regions of South America, but may be described as olive-brown or bronze. Their color as well as their physical peculiarities have been ascribed to the fact of their occupying a country elevated from 7,500 to 15,000 feet above the sea, where the climate is always cool and dry. Their features are strongly marked, and according to D'Orbigny have a closer resemblance to those of the Mexicans than those of any other American nations, from which they are further distinguished as having the least beard. What is known as Peruvian civilization, art, and religion, attests their intellectual and moral characteristics and capabilities. Previous to the conquest they had made considerable advances in science, apparently without foreign aid or suggestions. They had a decimal system of numeration, a circumstance which widely distinguishes them from the Mexicans, whose system was vigintesimal. They had observed the solstices and equinoxes, and accurately determined the length of the solar year. "They cultivated poetry and music," says Prichard, "and the roundelays of the Incas were celebrated by the Spanish writers for their pathetic and beautiful simplicity. Their language was harmonious, graceful, and formed by the most artificial system of inflections and combinations. Their religion was, if we may apply such epithets to any uninspired faith, the mere result of the inward light of an untaught human mind, in the highest degree spiritual and sublime. They recognized in Pachacamac the invisible God, the creator of all things, supreme over all, who governed the motions of the heavenly bodies, and whom they worshipped without image or temple in the open air; while to the sun, his visible creature, they erected temples, honored him with costly gifts, and with rites performed by consecrated virgins." Some authors classify the ancient Peruvians under three heads: the Aymares (including the Quichuas and Aymares), the Chinchas (corresponding with the Changos of Prichard), and the Huancas or Atacamas.

QUICKSILVER. See Mercury.

QUIETISM. See Molinos.

QUILIMANE, or Kilimane, a town of the Portuguese territory of Mozambique, on the E. coast of Africa, situated on the left bank of the river Quilimane, the N. arm of the Zambesi, 15 m. from the sea, in lat. 17° 52′ S., long. 37° 1′ E.; pop. about 15,000. It is irregularly built, some of the dwellings being of [illegible] some of mud, and many of reeds and grass. Its chief exports are gold and ivory.

QUILLWORT, a submerged aquatic plant with rush-like or quilled leaves, proceeding from a common contracted stem (*cormus*), which emits roots from beneath. From its evergreen condition throughout the year, it has received the generic name of *isoëtes* (Gr. ισος, equal, and ετος, year). Its organs of propagation are lodged in chambered conceptacles (sporocarps) enclosed in the bases of the leaves, and filled with minute, irregularly spherical bodies (*oophoridia*), which at first cohere in fours. The quillworts belong to the natural order [illegible]*dropterides* or water ferns, and are cellular cryptogamous plants. The lake quillwort (*I. lacustris*, Linn.) is the most common form, and is found on the bottom of ponds and in [illegible] streams in New England. Other species are known in the southern and western states.

QUILOA, a town of E. Africa, on an island of the same name off the coast of Zanguebar, in lat. 8° 57′ S., long. 39° 37′ E.; pop. about 7,000. It has a fort built of mud and [illegible] and whitewashed, and is partly surrounded with walls. The streets are narrow, and many of the houses are two stories high; and there is a large mosque with 25 domes. At one time an extensive trade was carried on, but it is of little importance now. Quiloa forms a dependency of the sultan of Zanzibar. When the Portuguese navigators first visited that part of the world, Quiloa was a large town, and the capital of a prince who ruled over Sofala and Mozambique. In 1505 it was taken and burned by Francisco de Almeida, and the Portuguese afterward built a fort, but were compelled to abandon it in consequence of the unhealthy nature of the climate. It subsequently became a slave depot, and continued to be enriched by that traffic till the early part of the 19th century, when the island was captured by pirates from Madagascar, who held it until they were expelled by a force sent from Zanzibar by the imam of Muscat.

QUIN, James, an English actor, born in London, Feb. 24, 1693, died in Bath, Jan. 21, 1766. His grandfather had been lord mayor of Dublin, and his father removing to that city after his birth, James was educated at the university there, and when 20 years old went to London, and commenced the study of the law in the Temple. Having obtained an engagement at Drury Lane in 1717, he at first acted subordinate parts, but gained some reputation in the character of Bajazet. In 1721 he secured his fame by acting Falstaff in the "Merry Wives of Windsor," and greatly increased it in 1731 by excelling Barton Booth in the part of Cato; and on the appearance of Garrick in 1741, he stood at the head of his profession.

In 1748 he retired from the stage, thereafter residing at Bath, but in 1749 appeared in Thomson's tragedy of "Coriolanus." He played for the last time, as Falstaff, on March 19, 1753, refusing to play afterward because he had lost his voice. He received a pension from George III., whom in his youth he had instructed in elocution. He once released Thomson the poet from imprisonment in a sponging house, paying his debts to the amount of £100, although he was personally unacquainted with him at the time.

QUINARY SYSTEM. See Entomology, and Ornithology.

QUINAULT, Philippe, a French dramatist, born in Paris, June 3, 1635, died there, Nov. 26, 1688. He was the son of a baker, and was patronized by the dramatist Tristan l'Hermite. When about 18 years old he produced on the stage a 5-act comedy, *Les rivales*, which was received with applause. He studied law, got rich by marriage, assumed the title of counsellor before the parliament, and bought an office as auditor in the court of exchequer, and afterward a post in the royal household. In 1665 he produced his best comedy, *La mère coquette, ou les amants corrigés*. He was less fortunate in the serious drama, *Astarte*, his only tragedy which is now remembered, owing its notoriety to the ridicule of Boileau. In 1672 he became acquainted with Lully the composer, and wrote lyrical tragedies to which Lully furnished the music. In conjunction with Molière and Corneille, he wrote some parts of *Psyché*, an operatic ballet extemporized for one of the royal festivals at Versailles. He was a member of the French academy. His complete works were published in 1739 and 1778 (5 vols. 12mo.); his *Œuvres choisies* in 1842 (2 vols. 8vo.).

QUINCE, the fruit of a low, straggling tree (*Cydonia vulgaris*, Persoon), belonging to the natural order *pomaceæ*, which likewise includes the medlar, apple, pear, &c. (See Pear.) The common quince tree has a crooked stem, rising to the height of 8 to 15 feet; irregular and twisted branches, its bark smooth and brownish black; leaves ovate, obtuse at the base, entire, dusky green above, tomentose beneath; the flowers large, the calyx tomentose, and the sepals serrulated and somewhat leafy; the corolla of 5 pale red or white petals, which are no longer than the sepals; stamens 20 or more in a single row; fruit large, globular, oblong or pear-shaped, of a rich orange or yellow color when ripe, and emitting a peculiarly pleasant smell, but which to many persons is disagreeably strong. The classical generic name of the quince tree indicates its connection with Cydon, a city of Crete, but it is thought not to have been indigenous to that country. At the present day it occurs spontaneously in the south of France and on the banks of the Danube.—The quince is mentioned by Columella and by Pliny, who gives directions how it can be kept for winter use. It was in much esteem and veneration among the ancients, and was regarded as an emblem of love and happiness. Many myths are connected with it, and from the rabbinical writings it is even thought to have been the forbidden fruit. The earliest herbalists make mention of the quince tree as very common in the gardens of England. There are several varieties, but the most distinct are the pear-shaped, which is doubtless the typical form, the apple-shaped, and the Portugal. The first is the most abundant bearer, but its fruit is not so much esteemed as that of the second; this however is only a seedling variation, and its seeds when sown produce the pear-shaped quince as frequently as its own form. To reproduce it with certainty, recourse must be had to other means. The Portugal is not so good a bearer as the others, nor is the color of its fruit of so deep an orange. The orange quince is a local sub-variety, and so is the large-fruited quince of the fruit catalogues.—The quince tree is readily propagated by its seeds, which ripen as well as those of the apple, and can be sown in the same manner; layers produce fine plants, and even cuttings, put in the ground in autumn or early in the spring in some moist shady situation, root easily. The better sorts can be also budded, using the inferior kinds for stocks, or even the common thorn. The tree used as a standard needs little pruning, removing the lateral branches merely, or thinning the top to secure larger fruit. It delights in a rich mellow soil, and will repay the cost of annual top-dressing with manures. Care should be taken to examine the base of the trunk for the ravages of the borer (*saperda bivittata*, Say), which prove very destructive. A remarkable yellow fungus (*ceratitium Cydoniæ*) sometimes attacks the young fruit and causes a considerable loss. The quince tree is used for stocks for budding or engrafting the pear when needed for dwarfs; the best sorts of quince stock are the Portugal, which has a more vigorous and free growth, and a variety called the Angers. As a fruit the quince is chiefly used for preserving with sugar, and in making marmalades, jellies, &c. A wine is made of it in England. The mucilage which envelopes the seeds is useful in relieving sore throat.—The Chinese quince (*C. Sinensis*, Thouin) is a very handsome species, growing 20 feet high in an arborescent manner; its leaves are ovate, acuminated at both ends, acutely serrate and shining, smooth when full grown; the flowers rosy, becoming red; fruit egg-shaped, large, hard, almost juiceless, and of a greenish color. The Japan quince (*C. Japonica*, Pers.) is one of the most desirable shrubs in cultivation, and is conspicuous for its rich and abundant crimson blossoms in early spring. It was known in England about 60 years ago, and has found favor widely in America for nearly the same period. Its stem is low, straggling, and bushlike, throwing up numerous spiny suckers, which fit it for use in making live hedges; its leaves are oval, somewhat wedge-shaped, crenately serrated, smooth on both sides, stipules reniform and serrated; flowers mostly 2 or 3 together, calyx smooth, the sepals short, obtuse, entire; corolla with 5 rich crimson petals; stamens in 2 rows; fruit small, hard, austere, with a singular aromatic and peppery perfume, and of a greenish yellow color. The Japan quince trained to a wall or upon a framework produces a very fine effect, and when trained to a single stem its drooping branches are very picturesque. It is propagated from pieces of its roots, from suckers and layers, or from cuttings. A very distinct variety with creamy and blush-tinted flowers, and another with semi-double red flowers, are known to gardeners. Other superior varieties are the results of the labors of floriculturists.

QUINCY. I. A township of Norfolk co., Mass., 8 m. S. by E. from Boston, bordering on Quincy bay, and on the line of the Old Colony and Fall River railroad; pop. in 1860, 6,788. About 3 m. from the bay, in an elevated range, are immense quarries of granite, employing over 800 men, and yielding to the annual value of about $250,000. The village is beautifully situated on a plain in the centre of the township. It contains a town house, a newspaper office, 2 banks, and 8 churches, viz.: 2 Congregational, 1 Episcopal, 2 Methodist, 2 Roman Catholic, and 1 Universalist. It was formerly called Braintree, and is noted as the birthplace of John Hancock, John Adams, John Quincy Adams, and Josiah Quincy, jr. In 1828 a stone church was erected, containing monuments to the memory of John Adams and his wife, and John Quincy Adams and his wife. A horse railroad is in process of construction connecting Quincy with Boston. II. The capital of Adams co., Ill., on the Mississippi river, 160 m. from St. Louis, 110 m. W. from Springfield, and 268 m. S. W. from Chicago; pop. in 1860, 13,718. It is handsomely situated on an elevated bluff commanding an extensive view of the river and country around, and has an active trade. It contains the court house, a number of manufacturing establishments, 3 banks, 5 newspaper offices, and 21 churches. It has very extensive railroad communications, being the W. terminus of the Chicago, Burlington, and Quincy, and the Quincy and Toledo railroads, and is also connected with St. Joseph, on the Missouri, by a railroad to Palmyra.

QUINCY. I. JOSIAH, jr. (so known to his contemporaries to distinguish him from his father of the same name, who survived him), an American lawyer, orator, and political writer of the period just preceding the revolution, born in Boston, Feb. 23, 1744, died at sea off Gloucester, Mass., April 26, 1775. He was graduated at Harvard college in 1763, and studied law with Oxenbridge Thacher, jr., a barrister in large practice, whom on his death in 1765 he succeeded in his business and took at once the highest rank in his profession. After the passage of the stamp act, notwithstanding the military occupation of Boston by the British, he fearlessly denounced the oppressions of the parliament and its violations of the rights of the colonists, in public meetings and through the press. Though of a slender frame and imperfect health, he had a voice of great compass and beauty, a graceful and passionate delivery, and a flow of thought at once fervid and logical, which placed him in the first rank of the orators of that day. His name was always joined by his contemporaries, and still continues to be so, with those of James Otis and Joseph Warren, as men who were most powerfully influential in causing the revolution, though death or calamity hindered them from assisting in its progress and its triumph. Beside his speeches in town meetings and other public assemblies, in Faneuil hall and the Old South church, he inflamed and directed the public sentiment of that critical time by his bold and animated appeals through the newspapers of the day, under various signatures, but with no real concealment of authorship. In May, 1774, he published his principal political work, "Observations on the Boston Port Bill, with Thoughts on Civil Government and Standing Armies." This was published with his own name on the title page, and produced a strong and permanent influence on the opinions and purposes of the period. In it, as in his anonymous writings, he distinctly states the inevitable necessity of the appeal to arms which soon followed, but which few were then ready to regard as unavoidable, and plainly shadows forth independence as the necessary result, which still fewer were then ready to contemplate. This work was republished in London, and excited much attention on the part both of ministerialists and the opposition. It bears marks of having been written in feverish haste at moments snatched from professional avocations. He had not even time to correct the proofs, which service was performed for him by Samuel Adams. An attempt was made to deter him from publishing this work by an elaborate and well written letter sent to him anonymously, but believed to have proceeded from a high functionary of the government. To this letter he made a brief but spirited reply through the "Massachusetts Gazette," and forthwith proceeded with the publication. Previously to this, however, after the "Boston massacre" of March 5, 1770, he gave the strongest proof possible of his moral courage and sense of professional duty. Immediately upon the arrest of Capt. Preston and the soldiers who fired upon the people, application was made on their behalf to Mr. Quincy and to John Adams to act as their counsel. This duty they accepted in the face of the strongest popular opprobrium, and in the case of the former of an impassioned remonstrance from his father. They were not deterred from their duty, however, and on the trials the next autumn the acquittal of the prisoners justified their course, and did honor to the sense of justice and self-control of the eople of Boston. In 1773 the severity of his rofessional labors and the political excitements f the time told so powerfully on Mr. Quin y's health, that he was obliged to remove imself from both for a time. He accordingly ailed for Charleston, S. C., and paid a visit of few weeks to that city, returning on horse ack in the spring. During this tour he put imself in communication with the principal higs of the southern and middle states, and tablished a plan of correspondence between hem and the Massachusetts patriots which was f material service in organizing the revolu ion. The health of Mr. Quincy again yield ng to his severe application to affairs, he was revailed upon in Sept. 1774, by the urgency f political as well as personal friends, to pro eed to England on a private mission for the opular cause, as well as for the good of his ealth. This visit, occurring at so critical a oment, excited considerable notice in London. e had interviews, at their own request, with ord North and Lord Dartmouth, and was in onstant intercourse with Dr. Franklin, Col. artley, Gov. Pownall, the earl of Shelburne, ol. Barré, Dr. Priestley, Dr. Price, and other minent friends of America. Lord Hills orough denounced him with Dr. Franklin, in is place in the house of lords, as a man who, the government did its duty, "would be in ewgate or at Tyburn." The results of his ission he and the English whigs regarded as f the utmost importance to the American ause; but they were of a nature that could ot be committed to writing with safety to the arties concerned. He accordingly prepared o return early in the spring of 1775, against he advice of Dr. Fothergill, postponing his hances of recovery to the discharge of a pub c duty. Unfortunately, however, he grew orse and died just before arriving. Almost is last words were that he should die content ould he have but an hour's interview with amuel Adams or Joseph Warren. The revo ution had been begun at Lexington, but he had ot the consolation of knowing it. His death aused a general grief throughout the country, s his labors in exciting the revolution were niversally acknowledged, and the loss of the ervices he was expected to render in its prosecu ion, had he survived, was universally lamented.

I. JOSIAH, an American statesman, son of he preceding, born in Boston, Feb. 4, 1772. e received his early education at Phillips cademy, Andover, Mass., and was graduated Harvard college in 1790. He studied law ith Judge William Tudor of Boston, but the ractice of the profession had fewer attractions r him than the stirring politics of that day, hen the people of the country had just begun organize themselves into parties, under the erce excitement of the French revolution. e joined the federalists at the birth of the arty, and remained constant in his allegiance it to the last. He was early selected as one ted by hereditary dispositions as well as by the turn of his talents and studies for public life. He was a candidate for congress in 1799, but was defeated in that year and twice afterward by the democratic candidate. In 1805 he was elected and served until 1813. During the whole term of his parliamentary life the federal party was in a hopeless minority. Its only service was one of protest, and Mr. Quincy was its most prominent and efficient member in the discharge of this duty. With great readiness in debate, earnestness and fervor of speech, quickness of wit, keenness of satire, and the most thorough personal intrepidity, he was a constant thorn in the side of the administrations of Jefferson and Madison. The embargo, the war of 1812, the erection of the Orleans territory into a state, which were the chief public measures of that period, he encountered with the most untiring hostility. He was one of the first, if not the first, among northern men to denounce the slaveholding interest as a rising and dangerous tyranny. In 1813 he declined a reelection, and returned to private life, dividing his year between Boston and his country seat at Quincy, where he applied himself with energy to scientific farming. He was immediately elected a member of the state senate, where his opposition to the war was as earnest as in congress, and quite as annoying to the administration, inasmuch as the federalists had a large majority in both houses. He joined in the protest of the legislature against the war and the admission of Louisiana, and reported the famous resolution, occasioned by a proposed vote of thanks to Capt. Lawrence for the capture of the Peacock, to the effect that in a war waged without justifiable cause and for conquest and ambition, it was not becoming a moral and religious people to express approbation of exploits not immediately connected with the defence of the seacoast and harbor. He remained in the state senate until 1821, when he was dropped by the federal managers under an impression that his uncompromising course had weakened his popularity. His immediate election to the house of representatives at the head of the ticket showed that they misunderstood the people, and he was elected speaker, which office he held while in the house. In 1822, however, he resigned to take the office of judge of the municipal court of Boston. During his short term of judicial office he first laid down the law in the case of Joseph T. Buckingham, indicted for a libel on John N. Maffitt, that the publication of the truth, with a good intention and for a justifiable end, is not libellous. This ruling excited great discussion and no small censure at the time, but is now the acknowledged rule of law in this country and in England. The next year, 1823, he left the bench to become the mayor of Boston, being the second incumbent of that office. In its administration he conducted himself with preëminent decision, energy, and capacity, and left to municipal magistrates everywhere an excellent example of industry, disinterestedness, and fidelity. In 1828 he lost his election through the influence of the fire department, which he had reorganized, in consequence of his refusal to appoint a person he deemed incompetent as the chief engineer. The presidency of Harvard university was then vacant through the resignation of Dr. Kirkland, and the corporation at once and unanimously offered it to him. There was some objection on the part of the clergy to the appointment of a layman to a post which had almost always been filled by one of their order; but the voice of the general public approved the selection, and the result justified it. He was inaugurated in June, 1829, and held the post until Aug. 1845, when he resigned, followed by the regrets of all the members and friends of the college. A man of the world and of business, as well as a lover of letters, he conducted the affairs of the college and administered its discipline in a manner which left it in a state of high prosperity. Since then he has lived a strictly private life, except in the year 1856, when he took a prominent and influential part, by speech and through the press, being then in his 85th year, in the effort to elect Col. Fremont to the presidency. He is still living (1861) in full possession of all his mental faculties and the thorough enjoyment of life, the patriarch of the public men of America. Beside many speeches in congress and orations on particular occasions, the chief of which are those on July 4, 1826, the jubilee of independence, on the second centennial celebration of the settlement of Boston, Sept. 1830, and the second centennial of Harvard university, Sept. 1836, Mr. Quincy has published the works named below: "Memoir of Josiah Quincy, Jr., of Massachusetts" (Boston, 1825); "History of Harvard University" (2 vols., Cambridge, 1840); "The Journals of Major Samuel Shaw, the first American Consul at Canton, with a Life of the Author" (Boston, 1847); "The History of the Boston Athenæum" (Cambridge, 1851); "The Municipal History of the Town and City of Boston during two Centuries" (Boston, 1852); "The Life of John Quincy Adams" (Boston, 1858); "Essays on the Soiling of Cattle" (Boston, 1859). III. **Edmund**, a political and miscellaneous author, son of the preceding, born in Boston, Feb. 1, 1808. He was graduated at Harvard college in 1827. He has published "Wensley, a Story without a Moral" (Boston, 1854), and has been a frequent contributor to literary periodicals and political newspapers. He has long been prominent among the Garrisonian abolitionists.

QUINCY, Quatremère de. See **Quatremère de Quincy.**

QUINET, Edgar, a French historian, poet, and philosopher, born at Bourg-en-Bresse, department of Ain, in 1803. Having visited Germany and acquainted himself with German philosophy, he published a translation of Herder's *Ideés sur la philosophie de l'histoire de l'humanité* (3 vols. 8vo., 1827), with an introduction, and in 1828 accompanied a s tific commission to the Morea, where h lected material for his *Grèce moderne et* *ports avec l'antiquité* (8vo., 1830). Becn contributor to the *Revue des deux mon* published in it in 1831–'2 a number of p beside an ambitious poem entitled *Aha* which was reprinted in book form in He also contributed to the same periodi *poëtes de l'Allemagne* (1834); *La poésie* *Homère*, *L'épopée Latine* (1836), and *L'* *Française* (1837), and published *Voyag* *solitaire* (1836), and two poems: *Na* (1836), and *Prométhée* (1838), in which tempted to realize what he conceived the "democratic epopee." The mythical and philosophical pretensions of these p being little in accordance with French they had but moderate success. He con his studies on epic poetry in a brilliant *Sur l'épopée Indienne*, and, under the tit *Allemagne et Italie*, published a collecti philosophical and poetical compositions 8vo., 1839). Although appointed in 18 fessor of foreign literature at Lyons, he wr 1840 a sharp pamphlet against the policy government and the war in the East, und title of 1815 *et* 1840, which was followed *Avertissement au pays* in 1841. This di prevent his appointment in 1842 to the p sorship of the literature of southern Eu just established at the college of France. now produced *Le génie des religions*, and Michelet began a vigorous crusade ag the Jesuits, whom they both assailed u ingly in their public lectures. *Les Jé* summary of these lectures, which they p lished in conjunction in 1843, had an imm sale; and Quinet's own pamphlets, *De la l* *de discussion en matière religieuse*, *Répo* *quelques observations de Mgr. l'archevêq* *Paris* (1843), *L'ultramontanisme, ou la s* *moderne et l'église moderne*, and *L'inquis* *et les sociétés secrètes en Espagne* (1844), w scarcely less successful. But the war had be pushed too far for the government to overl it, and Quinet was suspended from his pro sorship. He occupied his leisure in visi Spain, and printed on his return *Mes vac* *en Espagne*, and *Le Christianisme et la ré* *tion Française* (1846). The next year, bei elected a deputy by his native town, he p ticipated in the reform manifestations, t up arms in Feb. 1848, and triumphantly re sumed his professorship at the college of Fran where he was proud "to inaugurate the re public in the very chair of a king's lecturer." He was elected colonel of the 11th legion of the national guard of Paris, and sent by his department to the constituent and legislative assemblies, where he took his seat among the ultra radicals. In the mean time he published his *Révolutions d'Italie* (1848), and on the French expedition to Rome issued a pamphlet, *Croi* *Autrichienne, Française, Napolitaine et Espagnole contre la république Romaine.* This was followed by *L'état de siége* (1849), *L'enseignement du peuple* (1850), and *Révision* (1851). By the decree of Jan. 9, 1852, he was exiled from France, and retired to Brussels, where he married the daughter of Asaki the Moldavian poet. His dramatic poem, *Les esclaves*, appeared in 1853, and a historical essay, *Fondation de la république des États Unis*, in 1854. In 1855 he published a remarkable article in the *Revue des deux mondes*, entitled *Philosophie de l'histoire de France*. He has since prepared an edition of his *Œuvres complètes* in 10 vols. 8vo. and 12mo., and to these in 1860 he added the last of his philosophico-poetical performances, *Merlin l'enchanteur* (2 vols. 8vo.).

QUINIC ACID. See Kinic Acid.

QUININE, or Quinia, an alkaline substance discovered by Pelletier in 1820, and procured from that variety of the yellow bark of the cinchona tree known as *calisaya*. This bark is the product of the *cinchona calisaya*, and is exclusively obtained from Bolivia and the S. part of the adjoining Peruvian province of Carabaya. This yellow bark has been commonly referred to the *cinchona cordifolia*, but it is ascertained that this species of the tree, which is common in New Granada, is unknown in the region where the true quinine bark is obtained. Several other species afford some quinine, but the other alkaloid, cinchonia, being more abundant in their bark, they are less valuable than the *C. calisaya*. The forests in which this tree is found are in the Bolivian provinces, Enquisivi, Yungas, Larecaja, and Caupolican, at distances of 8 or 10 days' journey from inhabited places. They are visited by parties of Cascarilleros, men devoted to this business, who make an encampment and roam through the region around, cutting down the trees they find and gathering the bark. That of the branches, being laid in the sun, rolls up and forms the quilled variety; the larger pieces from the trunk are piled up together and pressed flat by weights. When dry they are carried into the camp, where they are assorted for transportation. La Paz is the principal town in the interior where the bark is collected. It is thence sent to Arica on the coast, and from this and other ports is largely exported to Europe and the United States.—The manufacture of quinine is extensively carried on in Paris, in Stratford, England, and in Frankfort, from which place Russia, Prussia, and Austria are chiefly supplied with this medicine. In Philadelphia the business of extracting it from the bark is conducted in chemical establishments also upon a very large scale. The quinine in the process of its extraction is commonly converted into the sulphate, which is the salt chiefly employed in medicine, and of which from 2.5 to 3 per cent. is usually obtained from the yellow bark. The processes employed vary somewhat in different countries. From a strong decoction of the bark in water, acidulated with hydrochloric acid and filtered, the quinine may be set free from its combination with kinic acid and precipitated by addition of lime water; some lime combined with coloring matter falls with it. The precipitates are well washed with water, and the residuum is pressed, dried, and pulverized. It is then repeatedly treated with alcohol, which dissolves the quinine and leaves most of the impurities. These being separated, the solution is concentrated by evaporation to a brown viscid mass, which is impure quinia; or the tincture in the distilling vessel may be neutralized with sulphuric acid, and the alcohol being then distilled off, an impure sulphate is obtained which crystallizes on cooling. This is expressed, and then dissolved in boiling water to which purified animal charcoal has been added. It is filtered while hot, and then allowed to cool and crystallize. The purification is completed by again dissolving and crystallizing. Sulphate of cinchonia is commonly present, but being more soluble does not crystallize so readily as the sulphate of quinia, and remains in the mother liquor. This also contains what Liebig regards as an amorphous variety of quinine, which is analogous in its properties to uncrystallizable sugar; it is known as quinoidine, and possesses the same medical properties as the sulphate. Sulphate of quinine, or more properly the disulphate, is the medicine commonly known as quinine. It consists of one equivalent of sulphuric acid 40, two of quinine 324, and 8 of water 72=436. It is in fine, white, silky crystals, which on exposure to the air effloresce and lose their form together with their water of crystallization. It dissolves in 30 parts of boiling water, but separates on cooling. In ether it is slightly soluble. Alcohol when cold takes up one part in 60, and the diluted acids, tartaric and oxalic, dissolve it freely. In water acidulated with sulphuric or other acid it readily dissolves, and this property is taken advantage of in administering the medicine in a liquid form.—The effects of sulphate of quinine upon the system are similar to those of Peruvian bark, and it is now in general use as a substitute for this drug, being not only more easily administered in large doses, and better retained by the stomach, but also acting when required through the pores of the skin. It is a very powerful tonic and the most valuable remedy in intermittent and remittent fevers. It is exhibited in pills and also in solution, and it is found that its extremely bitter taste may be neutralized without affecting its medicinal efficacy by the addition of ¼ of its weight of tannic acid. In malignant intermittents it has also been applied externally in the form of an ointment. Quinine in large doses powerfully affects the brain, and even as ordinarily administered its effects are soon manifest in a feeling of tightness or distention of the head, ringing or buzzing sounds, and dulness of hearing. Deafness is often induced, which however passes off; but in very large doses the most serious effects have followed its use.—Quinine is often adulterated, chiefly with gypsum and other alkaline or earthy salts, also with sugar, gum, starch, stearine, caffeine, and various other substances. Any mineral substance not volatizable is detected by exposing the quinine to a red heat, by which the pure salt is entirely dissipated. Treatment with alcohol and other solvents exposes those impurities which are not also soluble in them.

QUINSY (*tonsillitis*, *amygdalitis*, or *cynanche tonsillaris*; Fr. *esquinancie*), common inflammatory sore throat. Though called tonsillitis, the inflammation is rarely confined to the tonsils themselves, but involves the pharynx, the soft palate, and the uvula, and sometimes extends to the root of the tongue. It commences with a feeling of dryness and discomfort about the throat, and with pain in swallowing. On examination the mucous membrane lining the throat is found to be reddened and the tonsils more or less swollen. As the disease advances, the inflamed parts, at first preternaturally dry, become covered with visoid mucus, and the distress of the patient is greatly enhanced by the efforts which he is tempted to make to remove this secretion. In many cases suppuration occurs in one or both tonsils; when this takes place those organs are often enormously swollen, and together with the swollen and inflamed palate may render the breathing difficult and painful. In such cases the febrile reaction is strongly marked, the skin being hot and the pulse full and frequent; the patient is entirely unable to take nourishment, and the voice becomes thick and characteristic of the disease. The pain, exceedingly acute when the patient attempts to swallow, or to clear his throat of the viscid mucus which adheres to it, often extends to the ear, and sometimes is attended with partial deafness. The bursting of the little abscess formed in the tonsil is at once followed by great relief to the patient; the matter has a nauseous taste and often an exceedingly offensive smell. The disease, though very painful, is attended with little or no danger; it must be remembered, however, that the inflammation may by extension involve the larynx and thus prove fatal, and cases are on record in which death has occurred from the ulceration having involved a branch of the carotid artery.—The disease requires but little treatment. A mild purgative in the commencement and the use of warm water as a gargle are all that are necessary. Early in the attack powdered guaiac resin in doses of 20 or 30 grains, suspended in mucilage or sirup, several times a day, often gives great relief and seems to cut short the attack. Late in the disease stimulant and astringent gargles may be advisable.

QUINTANA, Manuel José, a Spanish poet and patriot, born in Madrid in 1772, died there, March 11, 1857. He was educated at Salamanca for the profession of the law, which he practised for a time at Madrid. His tragedy of "The Duke of Viseo," imitated from "The Castle Spectre" of M. G. Lewis, was performed in 1801, and was not successful. In 1802 he produced a small volume of lyric poems patriotic spirit immediately brought th favor, and in 1805 placed upon the s *Pelayo*, intended to rouse his countrym resist foreign oppression, which was well received. His "Lives of Disting Spaniards" (1807), and 3 volumes of se from Spanish poets, with critical notes prepared with the same patriotic motive the revolution of 1808 he published his to Emancipated Spain," and, both thro press and as secretary to the cortes regency, exerted himself to the utmost half of his country; but after the retu Ferdinand VII. from France in 1814, Q was confined for 6 years in the fortress peluna. After the revolution of 1823 mained in Estremadura until the acces Isabella II., whose education he had s tended, when he was recalled to office, a peer, and crowned with laurel. His plete works have been published in neyra's *Biblioteca de autores Españoles* (

QUINTILIAN (Quintilianus), Marc bius, a Roman rhetorician, born prob Calagurris in Spain about A. D. 40, died 118. He was educated at Rome, study der Domitius Afer, and after revisiting tive country returned with Galba, and the profession of an advocate, and al came distinguished as a teacher of ele Among his pupils were the younger Pliny the two grand-nephews of Domitian, by monarch he was invested with the co honors and title. He was the first wi ceived from the imperial treasury a re salary of 100,000 sesterces a year, whi given him by Vespasian. For 20 years taught oratory with such success, that his became synonymous with excellence in th His great work was a treatise on the edu of an orator, entitled *De Institutione Or Libri XII.* There are 164 declamations as to him; and he wrote also a work *De C Corruptæ Eloquentiæ*. The first complete of the "Institutes" was discovered by P Bracciolini in the monastery of St. Gall w attending the council of Constance. The *tio princeps* was printed at Rome by Phi Lignamine (fol., 1470); the best edition is begun by Spalding and finished by Zump vols. 8vo., Leipsic, 1798–1829). The "Insti tutes" have been translated into English Guthrie (2 vols. 8vo., London, 1756), by Pa sall (2 vols. 8vo., 1774), and by Wats vols., London, 1856).

QUITCLAIM, a word often used in de and usually in connection with words of g and conveyance, when the grantor or selle tends to convey to the grantee or buyer al right, title, interest, and estate of the gra but without any warranty whatever, wh of title, quantity, or any thing else. Sometim deed purports to be a deed of "grant and itclaim," when the grantor adds to the words grant and conveyance, words of limited warranty; as, for instance, warranty against himlf and all persons claiming by, from, through, under him. Even this limited warranty, nd still more a general warranty, would estop he grantor from ousting the grantee by any etter title, not coming through the grantor, hich the grantor might acquire subsequently his deed. But if the deed were one of grant nd quitclaim only, without any warranty, the rantor might then assert such a title. For xample, A sells and conveys to B, by grant nd quitclaim only, for a full price, an estate which it turns out that A has no title. But subsequently acquires title to it by inheritance from the true owner. A may now get he estate from B; but not if he granted with arranty, because if he then took the estate his better title, B would turn round upon im on the warranty and get the estate back gain. Quitclaim is also used in receipts, usully with such words as release and discharge, hen it is intended to signify that the party iving the receipt or release agrees never to ake any claim against the other party for any xisting debt.

QUITMAN, John Anthony, an American olitician and soldier, born in Rhinebeck, utchess co., N. Y., Sept. 1, 1799, died in atchez, Miss., July 17, 1858. His father was native of Prussia, his mother of Curaçoa. In is 16th year he was employed as tutor at Hartwick academy, near Cooperstown; at 18 s professor of English literature at Mount Airy college, Germantown, Penn.; and at 19 e travelled on foot to Chillicothe, where he ntered a law office, supporting himself meanwhile by teaching. He subsequently accepted clerkship in the U. S. land office, Delaware, O., where he was licensed to practise law. In 821 he removed to Natchez, Miss., became a artner of Mr. William B. Griffith, a prominent lawyer, was elected member of the legislature in 1827, appointed chancellor of the state n 1828, and subsequently continued in that office by election, and was chosen a delegate to the convention for revising the state constitution. Resigning the chancellorship in 1834, he was elected to the state senate, and chosen its presiding officer. While performing this duty, a vacancy happening in the executive office, its functions devolved on him in 1836; but he soon after withdrew from political life, and raised a small body of men with whom he joined the Texans in their struggle for independence. He remained in the field until the capture of Santa Anna, when, considering the war at an end, he returned to Natchez and resumed the practice of his profession. At the same time he discharged the duties of majorgeneral in the militia, director of the state hospital and of the Natchez lyceum, trustee for the state university, and president of the board of trustees for Jefferson college, beside superintending several large sugar and cotton estates. In July, 1846, he was appointed brigadier-general in the U. S. army, and ordered to report to Gen. Taylor at Camargo. Quitman's brigade consisted of the 1st Mississippi and 1st Tennessee regiments. At the battle of Monterey, which soon followed, he distinguished himself by his successful assault on Fort Teneria, and his daring advance into the heart of the city, fighting from house to house, and driving the Mexicans from barricades and batteries. Soon after the capitulation of Monterey, at his own request, he was ordered to report to Major-Gen. Scott at Tampico. At the siege of Vera Cruz, he commanded in the first sharp engagement with the enemy, and subsequently led an expedition against Alvarado, in conjunction with the naval forces under Com. Perry. He rejoined the army soon after the battle of Cerro Gordo, and formed part of the advance under Gen. Worth that took possession of the city of Puebla. Here he was breveted majorgeneral for gallantry at Monterey, and received a sword voted him by congress. In the attack on Chapultepec his division formed one of the assaulting columns. He stormed the formidable works at the base of the hill, and promptly pushed forward to the Belen gate, which he carried by assault, and planted the colors of the South Carolina regiment, thus taking possession of the city of Mexico, in advance of the general-in-chief, who, with Worth's division, was approaching by the San Cosme road. During the night, in the face of a tremendous fire, he erected batteries to support an attack upon the citadel, a formidable work immediately in his front; but early in the morning it surrendered. When the general-in-chief arrived, he appointed Quitman governor of the city. He retained the office until he had thoroughly established order and discipline, and then solicited leave to return to the United States. He was soon after, and almost by acclamation, elected governor of Mississippi. While exercising the duties of this office, upon the finding of a federal grand jury in Louisiana, he was threatened with arrest for alleged complicity with Gen. Lopez in organizing an expedition to Cuba. Denying the right of the federal government to arrest the chief magistrate of a state, he urged a suspension of proceedings until the expiration of his term of office, pledging himself then to demand a trial; but this being refused, he resigned his office, not wishing to provoke a collision with the federal authorities. He went to New Orleans in the custody of the U. S. marshal, but after an abortive effort to obtain evidence, the prosecution was abandoned. The democratic party in Mississippi immediately renominated him for governor, and he entered upon the canvass, his opponent being Gen. H. S. Foote. The adjustment or compromise measures of 1850 constituted the issue, Quitman being strongly adverse to them. While this canvass was progressing, the people of Mississippi having, at an intermediate election for delegates to a state convention called to consider these measures, condemned the political views he was known to entertain, Quitman withdrew from the contest, and retired once more to private life. In 1855 he was elected to congress by a large majority, and in 1857 was reëlected without opposition. During his whole term he remained at the head of the military committee. He took an active part in the general business and debates, but his parliamentary fame rests chiefly on his celebrated speech for the repeal of the neutrality laws, and his argument on the powers of the federal government, which gave him a position as the recognized head of the state rights party. He had never ceased to contemplate armed intervention in behalf of the Cubans as a duty, and he sympathized with every movement for the extension of American institutions in the western hemisphere. His life has been written by J. F. H. Claiborne (2 vols. 12mo., New York, 1860).

QUITO, the capital of the republic of Ecuador, and of a district of its own name, formed by a valley in the Andes, situated in lat. 0° 13′ S. and long. 78° 43′ W., on the E. flank of the volcano of Pichincha, 10,233 feet above the sea, being one of the highest inhabited points of the globe; pop. 80,000. Although almost immediately under the equator, its elevation imparts a degree of mildness and salubrity to its climate rarely found under the tropics. Its temperature averages about 60° F., and may be truly described as that of eternal spring. Fenced round by distant mountains, and immediately surrounded by plains and fertile valleys, the city forms the centre of one of the finest landscapes of the globe. Skirting the horizon may be discerned 8 snowy peaks of the Andes; and to the N. and S. of the city are the broad and beautiful plains of Añaquito and Turubamba, the first celebrated as the scene of the great battle between Gonzalo Pizarro and the viceroy of Peru, Blanco Nuñez de Vela, in which the latter was defeated. Quito has a number of large and beautiful public squares, of which the most celebrated are those of San Francisco, Santo Domingo, and Plaza Mayor, the last surrounded by the cathedral and government buildings. Each square has a stone fountain in its centre, supplied by subterranean aqueducts. There are many fine churches, of which the most famous are that of the Jesuits, adorned with columns, statues, and rich sculptures, and those of San Francisco and La Merced. The principal other edifices are the palace of the government, that of the archbishop, and the house of the Jesuits, now dedicated to various uses; one portion being occupied by the university; another by the seminary of San Luis, in which there is a public library of 15,000 volumes and a museum; a third by the mint; and a fourth by the barracks and armory. Quito is the residence of the sole archbishop of the country, and has, beside the university and the seminary of San Luis, a national college, a number of other educational establishments, 2 hospitals, and asylums for the insane and blind. The manufactures include coarse cotton and woollen goods, lace, hosiery, confectionery, and jewelry. There is a large traffic in grain, indigo, iron, steel, precious metals, wine, brandy, and oil, with Central America and Peru; and European manufactures are extensively imported.—The history of Quito goes back to a remote antiquity. Of its primitive rulers, tradition preserves the names of a number who were called Quita. About A. D. 280 the city is said to have been captured by certain foreign invaders, who, under the name of Siris, maintained their dominion until the invasion of the inca Huayna Capac, who subdued the old kingdom, destroying the last of the Siris in the sanguinary battle of Hatuntuati. Huayna Capac, in order to consolidate the kingdom, married the daughter of the Siri, and added to the red tassel of the incas the emerald which was the insignia of the kings of Quito. At his death he divided his kingdom between his two sons, Atahuallpa and Huascar, leaving to the first the sceptre of Quito, and to the second that of Cuzco. War however ensued between the brothers, in which Atahuallpa obtained control of the whole empire. But his triumph was of short duration, and he lived to find himself the prisoner of the Spanish adventurer Pizarro. Taking advantage of the capture of his king, Rumiñagui, one of the inca generals, usurped regal authority in Quito, but fled to the mountains on the approach of Sebastian Benalcazar. Under the Spanish dominion Quito, erected into a presidency, first formed part of the viceroyalty of Peru; afterward it was attached to that of Santa Fé, and subsequently restored to that of Peru, to which it remained attached until the independence of the country, when it was aggregated with Venezuela and New Granada in the republic of Colombia. On the dissolution of that republic in 1831, it was organized, with the districts of Azuay and Guyaquil, in a new republic under the name of Ecuador.

QUITRENT, certain kinds of rent, called quitrents, according to Blackstone, because the tenant thereby went quit and free of all other services. But this is the case with most rents; and the word came to be used generally in England to designate a small or merely nominal rent reserved, when the tenant or hirer paid in gross for the lease a large sum, about equal to the value of the land. The word is not much used in the United States, and cannot be said to have now any precise and definite technical meaning.

QUORRA. See Niger.

R

the 18th letter and 14th consonant of the English alphabet. It is a lingual and a uid, or semi-vowel, being pronounced both fore and after most other consonants. It is und in all languages except the Chinese and e tongues of some of the North American dians. The Romans borrowed it from the reek *rho* (P, ρ), which is derived from the ebrew and Phœnician *resh.* It is one of the st which children learn to pronounce, and ose who have been engaged in teaching perons deaf from birth to articulate, find the eatest difficulty in conveying any idea of its und to their pupils. The most common ode of pronouncing it is by an expiration hile the tongue touches the roof of the mouth ith a tremulous motion, as in the word rhetric. The tremulous sound is more distinct the Spanish *rr*, which indeed is not readily arned by Englishmen or Americans. It is equently exaggerated by the Irish and softned down by the English, who are more easily istinguished by their peculiar pronunciation f this letter than by that of any other.—The omans often added an *r* to words which they orrowed from the Greek, as *νυος*, *nurus;* *μαξ*, *murex;* and on the other hand often ropped it from the nominative case of nouns nd retained it in the oblique cases, as *æs*, *æris;* *s*, *oris.* It was interchanged sometimes with the words *arena*, *laribus*, *pignora*, *Furii*, *alerii*, and *Papirii* having been anciently ritten *asena*, *lasibus*, *pignosa*, *Fusii*, *Valesii*, nd *Papisii.* The same change is observed n some modern languages, as Eng. *hare*, Ger. *ase;* Eng. *was*, Ger. *war.* It is most frequently interchanged however with *l.* The hinese, who cannot pronounce *r*, always use n its place; the Japanese do exactly the rerse. (See L.)—As a Roman numeral R detes 80, or with a dash over it ($\bar{R}$) 80,000. he Greek P with a dash over it stands for 00, and with a dash under it for 100,000. As n abbreviation, R signifies *Roma*, *Romanus;* . P., *res publica;* R. C., *Roma condita.*

RAAB (Hung. *Győr* or *Nagy Győr;* anc. *rrabona*), a city of Hungary, capital of the unty of the same name, situated in a marshy ain at the junction of the Rabnitz and Raab, ear the entrance of the latter into the Danube, m. S. E. from Presburg and 67 m. W. N. . from Buda; pop. 18,000. It is the seat f a Roman Catholic bishop, has a cathedral d several other churches, and a number of her institutions for education, and carries on very active trade. Tobacco and cutlery, inluding swords, are manufactured. The town as a place of importance in the time of the mans. It was generally kept in a state of defence by the Hungarian kings, but after the battle of Mohács was twice taken by the Turks. A battle was fought under its walls in 1809, in which the French defeated the forces of the Hungarian nobles. The former fortifications of the town were razed after the French war. In the war of 1848–'9 the place was again very conspicuous. The Hungarians were defeated before it by Haynau, June 28, 1849.

RABATT, a town of Morocco, in Fez, at the mouth of the river Boo-Regreb, immediately opposite Salé, in lat. 34° 5′ N., long. 6° 46′ W.; pop. 21,000. The houses are well built, and it has some manufactures and trade. The environs are fertile, and figs, grapes, oranges, and cotton are produced.

RABBI (Heb., my master, lord, or teacher), a title of honor bestowed on the doctors of the Jewish law since the 1st century B. C. The Hebrew or Aramaic words *rab*, *rabba*, *rabban* (master), *rabboni* (my master), and *rabbenu* (our master), have also been employed in the same sense. In modern usage the title rabbi or rabbin is frequently applied to the distinguished Talmudic writers in general, including the authors of the Mishna and Gemaras, and sometimes in a more limited sense to the Jewish theological writers of post-Talmudic times, especially of the later periods of the middle ages, whose common dialect, a mixture of Hebrew and Aramaic, is therefore called rabbinical. The modern religious heads of Jewish communities or congregations are also called rabbis or rabbins, in which sense alone the title is sometimes used by the persons thus distinguished themselves. *Rab* is also used by the Jews of eastern Europe and others in the sense of the English Mr. or German *Herr*, being attached, both in conversation and writing, to the name of every married Jew enjoying a good reputation.

RABBIT, the common name of several species of the hare family, especially the *lepus cuniculus* of Europe and the *L. sylvaticus* of North America; the family and generic characters have been given under HARE. The European rabbit or cony (*L. cuniculus*, Linn.), the *lapin* of the French, is about 16½ inches long, with the tail 3 inches additional, and the ears also 3 inches; the tarsus shorter than in the hare; the general color gray brown, white below, the back of the neck rufous; tail white below, blackish above, but pencilled with dirty white; ears not tipped with black; compared with that of the hare, the skull has the muzzle, interorbital space, and incisive openings narrower; the mammæ are 5 pairs, 2 pectoral and 3 ventral. In the wild state the rabbit inhabits Europe, except the more northern portions, and N. Africa; it is thought to be originally from Spain, but, being hardy, has been carried to most parts of the world; it is easily distinguished from the hare by its smaller size, grayish color, and short feet and ears; it also differs from the hares in its burrowing habits. Unable to escape from its enemies by speed, it seeks safety in deep holes dug in dry sandy places, living in society in what are called warrens, with an ample supply of food at hand, in places suitable for burrows, such as sandy heaths covered by a prickly furze. Remaining concealed by day, they come out at twilight in search of food, and often do considerable mischief by digging up the newly sprouted corn and gnawing the bark from young trees; these warrens are often of large extent, and a source of great profit from the flesh and skins of the animals, which are caught in snares and traps, dug or drowned out, and hunted by dogs and ferrets. They are very prolific, beginning to breed at the age of 6 months, having several litters in a year and 5 to 8 at a time; the period of gestation is about 3 weeks, but, as the uterus is double, there may be two distinct litters at an interval of a few days; the young are born blind and naked, in a nest lined with the mother's soft fur; they are said to live 8 or 9 years. They seem to have social laws, the same burrow being transmitted from parent to children, and enlarged as the family increases. Rabbits and hares appear to be natural enemies; they are not met with in the same localities, and when they meet with each other almost always engage in deadly combat; when brought up together they do not produce a fertile offspring *inter se*, and hybrids probably never occur between them in the natural state. It has been estimated that in 4 years a single pair of rabbits would, if unmolested, become the progenitors of more than 1,250,000; but to check this increase we have the persecution of man and of carnivorous beasts and birds; their ravages are more than counterbalanced by their flesh, which forms a nutritious and easily digested article of food, and by their skins, which are used in making hats and are dyed to imitate more expensive furs. The name rabbit or cony is erroneously applied in the translation of the Hebrew Scriptures to the *shafan*, a small pachyderm with burrowing habits, described under Hyrax. Rabbits are easily domesticated, and in this state vary greatly in colors, size, and character of fur; black, white, and gray are the prevailing colors; in the silver-gray variety the hairs are white and black; the Angora rabbit is noted for the length and softness of its white fur; in the lop-eared varieties the size is 3 or 4 times that of the wild animal, and the ears are more or less bent downward from the base. When tame they do not pair like those in a wild state, and lose more or less the instinct of burrowing; their flesh is also inferior in flavor, though more delicate and digestible; the tame males not unfrequently kill the young.—The American gray rabbit (*L. sylvaticus*, Bach.) is about 16½ inches to the root of the tail, and to the end of the outstretched legs, that to the end of the hairs 2¼ inches; fur and soles of the feet full and soft; on the back lowish brown, lined with black, grayer on sides; on the rump mixed ash, gray, and pure white below; upper surface of the tail like the back, below pure cottony white; posterior edge of ears whitish, edges of the dorsal fur toward the tip black, the rest ashy brown, lead-colored at the base. This is among the largest of the short-eared *leporidæ* of America, being largest in the west and smaller and coarsest-haired in the south; it is found throughout the United States, from the eastern parts of New Hampshire to Florida, and to the upper Missouri, being most abundant in sandy regions covered with pines. It frequents woods and thickets, concealing its form, in thick bushes, or in holes by or under stones by day, coming out at night to feed; it is fond of visiting clover and fields, vegetable gardens, and nurseries of trees, where it does much mischief. It does not dig burrows like the European rabbit, but comes rather in the class of hares; when pursued it runs with great swiftness and with doublings to its hole in a tree or rock; though it will breed in enclosed warrens, it does not become tame, and has not been domesticated. It is very prolific, or else it would be exterminated by its numerous enemies; it often runs into the hole of the woodchuck, skunk, fox, or weasel, in the last 3 cases often falling a victim to the carnivorous inhabitant of the burrow; it is hunted by dogs, shot from its form, and caught in snares and traps; its flesh is much esteemed. It somewhat resembles the European rabbit in its gray color, but it does not change its colors like the latter; it is smaller and more slender. The sage rabbit (*L. artemisia*, Bach.), from the west and plains of Mexico and Texas, cannot be satisfactorily distinguished from the last species. The jackass rabbit or Texan hare (*L. callotis*, Wagn.) is so named from its very long ears, measuring about 5 inches, though the animal is rather smaller than the European hare; it is yellowish gray above, waved irregularly with black; upper part of tail black, sides gray, and whitish below; nape sooty black; it is found in Mexico, Texas, and Oregon. The long and slender legs indicate rapid locomotion and a capacity for making long leaps; it is a solitary and not very common species, and has not been found in California.

RABELAIS, François, a French author, born in Chinon, Touraine, in 1483, or perhaps a little earlier, died in 1553. The son of an apothecary or an innkeeper, apparently in good circumstances, he was sent at the age of 10 to the convent of Seuillé to be educated, but proved an idle pupil. At the monastery of La Baumette, where he was next placed, he showed equal distaste for study; but here he grew acquainted with the brothers Du Bel- the younger of whom was a fast friend protector to him in after life. How it pened that such a graceless young vagabond ered the order of Franciscans is not clear, probably it was in obedience to his father. mitted as a novice at Fontenay-le-Comte, he sed through the usual studies and ordeals, ordained priest in 1511, and made up for past laziness by devoting himself to the dy of ancient and modern languages, mas- ing the Latin, Greek, Italian, Spanish, Ger- n, English, Hebrew, and Arabic. Greek d especial attraction for him; and this in- lved him in serious quarrels with his fellow nks, who cherished such animosity toward t language that in 1520 the cells of Rabelais d his friend Ami were ransacked, and their cious Greek volumes confiscated. The ill ling grew so strong that the removal of the llenist became a necessity, and in 1524 he tained permission from Pope Clement VII. enter the order of Benedictines. He spent eral years at their house at Maillezais, but s no better satisfied than before, and in 30 abandoned the monastic life altogether, d repaired to Montpellier, the seat of the st celebrated medical school in France. re he attended lectures, and in 1530 was aduated as a bachelor in medicine and in 1537 a doctor. In 1532 we find him a hospital ysician at Lyons, and engaged in publishing notated and corrected editions of various med- l works of Hippocrates, Galen, and others. om 1533 to 1550 he published several editions a facetious production, in which he endeav- ed to destroy the faith in astrology which ll prevailed among the people. At Lyons o he published the first rough sketch of the range work upon which his fame rests: *Les its et dicts du géant Gargantua et de son fils ntagruel* (1533). Jean Du Bellay, his old hoolmate, now bishop of Paris, being on his y to Rome, where he had been appointed ench ambassador, took him in the capacity his physician, and thus enabled him to grat- y a long-felt desire of visiting Italy. In 534 he went back to Lyons for a short time superintend the printing of his edition of arliani's *Antiquitatis Romæ Antiquæ*. On s return to Rome he found that his patron d been promoted to a cardinalship; and rough his influence, aided by that of several her high dignitaries of the church, he suc- eded in obtaining from Pope Paul III. a bull, ted Jan. 17, 1536, which released him from e penalties he had incurred by the abandon- ent of his order. This instrument, which, ntrary to usage, was delivered to him gratis, lowed him "to return into any house of the Benedictine order which would receive him, d to practise physic on condition of doing so ithout hope of fee or reward." He now re- rned home and entered the abbey of St. Maur les Fossés at Paris, which was under the con- trol of Cardinal Du Bellay, and remained there in comparative ease and tranquillity until 1549, when he was presented by his protector with the comfortable living of Meudon. Here he applied himself faithfully to the duties of his ministry, and devoted his leisure hours to the completion of his great work, 3 books of which had already appeared. This being done in 1551, he once more repaired to Paris, published his 4th book, and spent his later years in devotional exercises at Meudon.—Such are the ascertained facts of a life which has been embellished by the most egregious fictions, originating generally in the idea that Rabelais was of necessity much like some of the characters he has depicted. He has been represented as a jolly buffoon, dreaming of nothing but good cheer and an easy life. There is not a particle of proof to substantiate this notion, while his profound and varied knowledge, the scientific works which he published, and his scholarly habits, are sufficient evidence of their falseness. The fanciful image of Rabelais that has lately been current must be set aside, and the writer must not be mistaken for one of his own heroes. No performance in French literature had greater success in its time, or has since attracted so much attention, as his "Gargantua and Pantagruel." It cannot be classed with any recognized order of works. It is a merciless attack upon monks, princes, kings, and all religious and political authorities. Amid its chaos of eccentricities and allusions to persons and events, of good sense and folly, of delicate thoughts and gross obscenities, commentators have tried in vain to find a historical explanation of the work. According to the most approved key, Gargantua stands for King Francis I.; Grandgousier for Louis XII.; Pantagruel for Henry II.; Picrochole for Maximilian Sforza, duke of Milan; Gargamelle for Anne of Brittany, the queen of Louis XII.; Badebec for Claude of France, queen of Francis I.; Grandgousier's... Grandejument de Gargantua for Diana of Poitiers; Panurge for the cardinal of Lorraine; and Frère Jean des Entommeures for Cardinal Du Bellay. Be this as it may, "the work was entirely in accordance with the taste of his age," as Vinet properly remarks; "and excellent minds which could appreciate its fine parts were also delighted with those that are repulsive to our taste." Lord Bacon styled Rabelais "the great jester of France;" while more recent judges have called him a "comic Homer." More than 60 editions of his great work have been published; the first complete one, containing the 5 books, appeared at Lyons in 1558. Among the subsequent editions, we may mention the two printed at Amsterdam in 1711 and 1741, with annotations by Le Duchat and La Monnoye (3 vols. 4to.); the standard modern *variorum* edition by Esmangart de Bournonville and Éloi Johanneau (9 vols. 8vo., Paris, 1823-'6); those of De l'Aulnay (3 vols. 8vo., 1835), of P. Lacroix (Bibliophile Jacob, 12mo., 1842, several times reprinted), and of Burgaud Des Marets and Rathery (2 vols.

12mo., Paris, 1857), the most convenient and acceptable of all, with a good biographical and critical notice, explanations, notes, &c. There are several English translations. That of Sir T. Urquhart, first published in 1653 (reprinted by the Maitland club, 4to., 1838), was adopted by both Ozell and Motteux as a basis. Their united translation is often reprinted; the last edition is by Bohn (2 vols., London, 1850). Sixteen private letters of Rabelais written while travelling in Italy were published in 1651.

RABUN, a co. at the N. E. extremity of Ga., separated from South Carolina on the S. E. by the Chattooga river, bordered N. by North Carolina, and drained by several small streams; area, about 350 sq. m.; pop. in 1860, 3,271, of whom 206 were slaves. It has an elevated surface, the Blue ridge extending along its S. E. border, and a considerable portion is covered with forests. The productions in 1850 were 64,699 bushels of Indian corn, 9,771 of oats, and 9,868 of sweet potatoes. There were 18 churches, and 644 pupils attending public schools. Capital, Clayton.

RACCOON (*procyon*, Storr), a genus of American plantigrade mammals of the bear family, of the section *subursinæ*. In this genus the size is comparatively small, the body stout, and the tail moderately long, bushy, and not prehensile; the muzzle is pointed, and the end very movable and slightly projecting; the teeth are: incisors $\frac{3-3}{3-3}$, canines $\frac{1-1}{1-1}$, premolars $\frac{4-4}{4-4}$, and molars $\frac{2-2}{2-2}$, in all 40, or with one upper true molar on each side less than in the bears. The shape is not unlike that of the badger, though the legs are longer; ears moderate, erect, and covered with hair; head broad behind and flat, with naked and large muffle; whiskers in 4 principal horizontal series, 5 or 6 bristles in each; feet 5-toed, with naked soles and no indication of webs; claws curved, not retractile, and sharp; though plantigrade when standing, the gait is rather digitigrade. The common raccoon (*P. lotor*, Storr) is 22 or 28 inches long, with the tail about a foot additional; the general color is grayish white, the tips of the long hairs black and giving this tint to the back; under surface dark brown; an oblique black patch on the cheeks, continuous with a paler one beneath the jaw, and another behind the ears; the end of muzzle, ears, and posterior part of cheek patch whitish; tail bushy, with the tips and 5 rings black, and the nearly equal interspaces rusty white; hind feet 4 inches long, dirty white above, the fore feet 2¾ inches; mammæ 6, ventral; there are anal glands which secrete a somewhat offensive fluid. Some varieties occur nearly black, others are nearly white. The raccoon is found generally over the United States, as far north as lat. 60° in the interior, as high as Newfoundland on the Atlantic, and further north on the Pacific; it is most abundant in the southern states, frequenting retired swamps covered with high trees and well watered. It is an excellent climber, in this way obtaining eggs and young birds; watching the soft-shelled turtle lay eggs in the sand, it uncovers and devours them; it seizes ducks as they come to the water; it is extremely fond of ripe and juicy corn, as well as of frogs and shell fish. It is not entirely nocturnal, and sometimes visits the fields and the poultry yard at midday; it feeds much on an inferior oyster in the southern states, hence called the raccoon oyster; in short the animal is truly omnivorous, eating, besides the above, rabbits, squirrels, and other mammals, fish, nuts, and honey. It has been generally supposed to dip its food in water before eating it, hence its specific name of *lotor* or washer; this it does not generally do in captivity, according to Bachman, and it is probably only an occasional habit of the animal. It hibernates during the coldest weather in the northern states; it is shy, and has an acute sense of smell; it brings forth about the month of May 4 to 6 at a time, in a nest in a hollow tree, about the size of half-grown rats, which utter a plaintive infant-like cry. It is a favorite sport of the southern negroes in winter to hunt "coons," driving them to a tree, and then climbing up and shaking them off, or felling the tree to bring them within reach of the dogs; they sell the skin to the hatters, and eat the flesh, which is generally very fat and tender, with a flavor of pig. Many are caught also in log and other traps, and are hunted by torchlight. In captivity it makes a very curious and interesting pet, being easily tamed so as to follow its master even into the crowded streets, ambling along in the manner of a bear, and picking his pockets adroitly of dainties.—The black-footed raccoon (*P. Hernandezii*, Wagl.), from Oregon, California, Mexico, and Texas, is somewhat larger, with the upper surface of the hind feet dark brown. The crab-eating raccoon (*P. cancrivorus*, Illig.), from Brazil and the northern parts of South America, is longer and more slender than the common species, grayish above shaded with brown and black, and yellowish below; the face is whitish, with a black band surrounding each eye; tail less distinctly annulated. Its habits are nearly the same as in the other species, but it is more arboreal; it is equally omnivorous, obtaining frogs, reptiles, and crustaceans when practicable; its flesh is also used as food. It is found on the sea coast and in the interior, and as far south as Paraguay; it has received its common name from one of its favorite articles of food.

RACHEL (Elisa Rachel Félix), a French actress, of Jewish parentage, born in Mumpf, Switzerland, Feb. 28, 1820, died at Cannet, near Toulon, Jan. 3, 1858. Her father, a peddler, pursued his calling in various parts of Switzerland and Germany, and was followed in his wanderings by his family, consisting of his wife, 4 daughters, of whom Rachel was the second, and a son. At Lyons, where they took up their residence temporarily, Rachel and her elder sister Sarah contributed to the common support by singing at the cafés and other pub-y resorts; and at Paris, whither the family moved in 1831, the two sisters similarly employed themselves on the boulevards. Choron, he founder of the royal institution for the udy of sacred music, struck by their performances, took them both under his instruction; ut finding that the talent of Rachel, to whom e gave the name of Elisa, was dramatic rather han vocal, he transferred her to the care of M. t. Aulaire, a teacher of declamation, who carefully grounded her in the chief female parts of he standard classical drama. Her admirable ersonation of Hermione at a private performance of *Andromaque* procured her admission in 1836 as a pupil of the *conservatoire*; and hortly after she obtained an engagement at the ymnase, where on April 24, 1837, she made er public début under the name of Rachel in La *Vendéenne*, a vaudeville written for her by Paul Duport. Whether the part was not adapted to her, or she had not yet acquired confidence in her own powers, the performance attracted little attention, and for upward of a year she did not again appear prominently before the public. In the mean time she studied assiduously under Samson, an actor and author of great experience, and on Sept. 7, 1838, startled the Parisian public by a personation of Camille in *Les Horaces* at the *théâtre Français*, so full of originality and tragic intensity as almost to obliterate the traditions of former actresses in the same part. Her merit, however, might not have been immediately appreciated had not Jules Janin, in the *feuilleton* of the *Journal des débats* of Sept. 10, declared that the tragedies of Corneille and Racine had become reanimated by the genius of Mlle. Rachel. At her third appearance the receipts rose from about 300 francs on the first night to 2,048, a fabulous sum for a performance of a classical drama; and thenceforth she stood alone on the French stage, confessedly the first actress of the day, and never probably rivalled in her peculiar walk of tragedy. The long neglected plays of Corneille, Racine, and Voltaire were speedily revived for her, and she appeared with peculiar success as Émilie in *Cinna*, Hermione in *Andromaque*, Ériphile in *Iphigénie*, Monime in *Mithridate*, Aménaïde in *Tancrède*, Roxane in *Bajazet*, Pauline in *Polyeucte*, Agrippine in *Britannicus*, Electre, Athalie, and Phèdre, the last being one of her greatest triumphs. In personating these characters she paid little regard to the cherished traditions of the stage, and the actors performing with her were frequently confused and even startled by tones and gestures so different from those established by custom as to appear to them wholly foreign to the play. The studied declamation of the old school was exchanged for an utterance at once natural and impressive, and the expression of her face, her gesture or attitude, scarcely less eloquent than her voice, conveyed a fulness and force of meaning which made each part a new creation in her hands. She excelled in the delineation of the fiercer passions, but jealousy and hatred were so subtly interpreted, that the mind was even less affected by what she expressed than by what she left to the imagination. A circumstance which contributed powerfully to her success was the rapidity with which she reached the full development of her powers; and others beside Janin were astonished that an obscure young Jewess, without education or assistance, should, as if by instinct, suddenly master the chief productions of French dramatic literature, and reveal in them beauties previously unsuspected. For several years she contented herself with performing in the old classic drama; but finding that the limited round of characters she assumed afforded her rivals a pretext for denying her the comprehensiveness and versatility of a great actress, she gradually formed a distinct *répertoire* from the works of modern and contemporary dramatists, in which she appeared with varying success. In *Judith*, by Mme. de Girardin, *Catherine II.*, *Virginie*, and *Le vieux de la montagne*, she made little impression; but in *Jeanne d'Arc*, *Marie Stuart*, and particularly in *Adrienne Lecouvreur*, a play adapted expressly to her talents by Scribe and Legouvé, she renewed the triumphs of Camille and Phèdre. The revolutionary outbreak of 1848 afforded her an opportunity for a remarkable performance, half spoken, half sung, of the *Marseillaise*. Subsequently she appeared in *Cléopâtre* and *Lady Tartufe*, written for her by Mme. de Girardin, in Victor Hugo's *Angelo*, in Dumas' *Mlle. de Belle-Isle*, in *Diane*, *Louise de Lignerolles*, and in Scribe's *Czarine*, which was the last new part studied by her. In none of these perhaps did she so completely satisfy her auditors as in the severe and lofty tragedy of the classic period, with which her genius seemed to have a close sympathy. Her theatrical income, originally 4,000 francs, soon rose to 80,000; and in 1849 she effected an arrangement at the *théâtre Français*, by which 6 months of absence in each year were allowed her. The receipts from her performances in the provinces and in England reached enormous sums, and during an engagement in Russia in 1853 she received 400,000 francs as her share. These emoluments, however, were gained at the expense of her health, which suffered under the fatigues of so arduous a life. In 1855, in company with her brother Raphael Félix and her sisters Sarah, Lia, and Dinah, and a complete *troupe* of actors and actresses, she made a professional visit to the United States, and first appeared before an American audience at New York as Camille in *Les Horaces*. She was interrupted in the midst of great success by the failure of her health; having played many times in New York and Boston, in which two places she cleared some $60,000, and then once in Philadelphia and once in Charleston, she went to Havana in a vain effort to regain her strength through the mildness of the climate, but finally returned to France a heavy loser and with little hope of recovery. She spent the following winter in Egypt, but all attempts to arrest the progress of her disease (consumption) proved unavailing. Rachel was slender, rather tall, and exceedingly graceful, with a finely modelled head, clear, pale complexion, and features full of expression. Her attitudes and movements were of surpassing beauty, and her voice was singularly deep, rich, and affecting. Though never married, she left two sons, one of whom, acknowledged as the son of M. Walewski, himself an illegitimate son of Napoleon I., has been ennobled as the count of Étiolles by Napoleon III.

RACINE, a S. E. co. of Wisconsin, bordered E. by Lake Michigan and drained by Des Plaines, Fox, Pike, and Root rivers; area, about 350 sq. m.; pop. in 1860, 21,368. It has a nearly level surface, principally prairie, and a very fertile soil. The productions in 1850 were 218,149 bushels of wheat, 78,847 of Indian corn, 175,655 of oats, 58,279 of potatoes, and 232,466 lbs. of butter. There were 6 saw mills, 2 tanneries, 5 newspaper offices, 18 churches, and 3,756 pupils attending public schools.—RACINE, the capital, is situated at the mouth of Root river on Lake Michigan, and on the line of the Chicago and Milwaukee railroad, 23 m. S. from the latter and 62 m. N. from the former; pop. in 1860, 7,822. It is built on a plain about 30 feet high, and has one of the best harbors on the lake, admitting vessels drawing 12 feet of water. The city is regularly laid out and well built. It contains a number of public offices, and is the seat of Racine college (Episcopal), founded in 1852. There are a number of manufactories, furnaces, machine shops, 3 ship yards, and 14 churches, viz.: 2 Baptist, 2 Congregational, 1 Episcopal, 1 German Evangelical, 1 German Lutheran, 3 Lutheran, 1 Presbyterian, 2 Roman Catholic, and 1 Universalist.

RACINE, JEAN, a French tragic poet, born at Laferté-Milon, Dec. 21, 1639, died in Paris, April 22, 1699. At the age of 16 he was admitted to the select school under the direction of the recluses of Port Royal, where he remained for 3 years studying the classics, and especially Greek, with eagerness. In 1660, on the marriage of the Spanish infanta Maria Theresa to Louis XIV., he dedicated to her an ode entitled *La nymphe de la Seine*, for which he received 100 louis and a pension of 600 livres. His relations insisted upon his becoming a priest; and accordingly he repaired to Uzès, where for several months he lived with his uncle, a canon, who promised him a benefice. But he could not give up poetry, and at last returned to Paris, where he published, toward the end of 1663, an ode, *La Renommée aux Muses*, which introduced him to the acquaintance of Boileau. A little before this he had been encouraged by Molière, who suggested the plan of his first tragedy, *La Thébaïde, ou les frères ennemis*. This play, performed in 1664, although it showed no striking merits either in construction or execution, was favorably received. *Alexandre*, brought out in the following year, was still more successful. In his *Andromaque* (1667) he first proved his real genius. In 1668 his 3-act comedy of *Les plaideurs*, a very lively imitation of the "Wasps" of Aristophanes, was performed; and in 1669 *Britannicus*, a masterly adaptation of some of the most powerful pictures of Tacitus. About this time Henrietta of England, wishing to place the veteran Corneille and his young rival in competition with each other, privately requested each to write a tragedy founded upon the illicit love of the emperor Titus and Queen Berenice. Unfit for the stage as such a subject was, the two poets eagerly accepted it. Racine succeeded in producing a series of touching scenes, embellished by the most exquisite poetry, so that his *Bérénice* has been properly styled a beautiful elegy in 5 acts; but the *Tite et Bérénice* of Corneille was a complete failure. Racine now wrote in succession 3 other tragedies: *Bajazet* (1672), which, contrary to all precedents, was founded on a contemporary occurrence in the Ottoman empire; *Mithridate* (1673); and *Iphigénie en Aulide* (1674), a remodelling of one of the plays of Euripides, which was pronounced by Voltaire the masterpiece of the French stage. *Phèdre*, which was produced three years later, is considered by some critics superior to *Iphigénie*. The duke of Nevers, the duchess of Bouillon, Mme. Deshoulières, and several other literary characters now put forward as a competitor to Racine a third rate poet named Pradon, for whose *Phèdre et Hippolyte* they secured popularity, while they managed to keep the public away from the theatre in which the true *Phèdre* was performed. This injustice inflicted a severe wound upon Racine's sensibility; and having married a very devout wife, and possessing in his office as royal historiographer a comfortable means of support, he resolved to cease writing for the stage, and devote his time to religious exercises, the education of his children, and the preparation of a history of the reign of Louis XIV. The manuscript of this work, which was never quite completed, was lost in a fire in 1726, with the exception of a fragment including 6 years, from 1672 to 1678. In the mean time Racine had acquired the favor of Mme. de Maintenon, who persuaded him to compose a drama to be acted by the pupils of the royal female seminary of St. Cyr. He therefore wrote in 1689 his biblical drama of *Esther*, in which he introduced choruses, and the performance was a decided success. The poet, encouraged by Mme. de Maintenon, undertook another play of the same kind, but of wider scope and proportions; the subject he chose was the fall of Athaliah. This was his last dramatic composition. Mme. de Maintenon now had doubts about the propriety of dramatic performances by the young ladies under her care; and when *Athalie* was completed in 1691, she caused it to be recited merely twice in a private room without costumes or scenery. When the ose was printed, it was scarcely noticed by e public. Boileau consoled his friend under e disappointment. "This is your finest work," said, "and the public will acknowledge it in e end." The prophecy was fulfilled, but not ing the poet's life. *Athalie* had to wait 25 ars to be performed at the *théâtre Français,* d it was not until about the middle of the th century that full justice was done to it. y the advice of Mme. de Maintenon, Racine w wrote a memoir in which he vividly de- cted the unhappy condition of France, and ggested some reforms at which Louis XIV. s highly offended; and his displeasure is d to have weighed so heavily upon Racine's nd as seriously to aggravate a disease of the er under which he had been suffering for veral years. He pined away, and at the d of a year or two breathed his last. He s buried, according to his desire, in the metery of Port Royal; and on the destruction the convent in 1711, his remains were trans- rred to the church of St. Étienne du Mont, Paris, where they now rest.—Beside his amatic works, Racine left prose writings rked by terseness, perspicuity, and elo- ence. This last quality is peculiarly strik- g in his speech before the French academy the reception of Thomas Corneille on Jan. 1685, when he paid a magnificent tribute of miration to the genius of the latter's great other. He also wrote a short sketch of the story of Port Royal, and two satirical letters answer to certain strictures of his old mas- rs upon dramatic poets. His familiar letters, ost of them addressed to his son or to Boi- au, are couched in an easy and elegant style. ost of his miscellaneous poems, consisting of es, *cantiques spirituels,* and epigrams, are a very high order of merit. The editions his complete works are many, and those of tragedies are numberless. The most con- nient of the latter are those published by dot under the supervision of Lefèvre, in the *hefs d'œuvre du 17e siècle* (2 vols. 8vo.), and the *Chefs d'œuvre de la littérature Française* vol. 12mo.), and the *variorum* edition by uandre. The most valuable editions of his *uvres complètes* are those of Pierre Didot the der (3 vols. fol., Paris, 1801-'5), with 57 en- avings by the first artists of the time, form- g a part of that magnificent collection known the *éditions du Louvre;* La Harpe (7 vols. o., Paris, 1807); Geoffroy (7 vols. 8vo., 09); and Aimé Martin, with notes selected om all the commentators (7 vols. 8vo., Paris, 30).—Louis, the son of the preceding, a ench poet and miscellaneous writer, born in ris in 1692, died in 1763. He was a pupil Rollin and a man of great piety. He wrote o didactic poems: *La grâce* (1722 or 1720), hich embodied the principles of Jansenism on the subject; and *La religion* (1742). th these poems, the latter especially, are re- arkable for clearness of composition and ele- nce of style, but are sadly deficient in point of power, greatness and imagination. The same may be said of his *Odes sacrées* and *Poésies diverses.* He wrote *Mémoires sur la vie et les ouvrages de Jean Racine* (2 vols. 12mo., 1747), decidedly to us his most valuable performance, a prose translation of Milton's "Paradise Lost," and other works. The best edition of his works is that of Lenormand (6 vols. 8vo., Paris, 1808). His poems have been published separately, and are still reprinted.

RADACK AND RALICK, names given by the natives to two chains of islands in the Pacific ocean, which, together with Brown's range, form the Marshall archipelago, extending from lat. 4° 45′ to 12° N., and from long. 160° to 177° E., and separated from the Gilbert or Kingsmill group by a channel about 120 miles wide. The Radack chain includes among other islands the Mulgrave, Mindi, Tagia, and Dawson groups; and the Ralick comprehends the Boston, Benham, Elmore, Schantz, and Eschsoltz. Most of these groups are composed of atolls connected at low water and separated by the sea at high tides; and the whole have the usual character of coral islands. The outer side of the reefs is unfathomable, and the lagoons within are more or less shallow. Some of these lagoons are very extensive, and are navigable for vessels of every description; but there are few passes sufficiently large to admit ships drawing much water. The principal productions of the islands are the cocoanut, breadfruit, pandanus, and taro. The Marshall archipelago is well peopled, and on some of the groups the inhabitants are very numerous. They are an able-bodied race of a copper color, and in general appearance have a strong resemblance to Malays. They have large canoes, and upon several occasions have made combined attacks upon vessels.—These islands were discovered by Captains Marshall and Gilbert, of the British navy, in 1788, on the passage from Sydney to China, after having landed the first settlers in Australia; and as Capt. Marshall was the principal officer of the expedition, his name has been applied by Krusenstern and others to the whole archipelago, while that of Capt. Gilbert has been given to the group lying to the S. There is considerable confusion in the original accounts, Gilbert having named some of the islands already named by Marshall; and Capt. Bishop, who 10 years afterward visited them and also named them, added thereby to the difficulty, which has been augmented by discrepancies in the longitudes given by all these officers.

RADCLIFFE, Ann, an English novelist, born in London, July 9, 1764, died there, Feb. 7, 1823. Her maiden name was Ward. At the age of 23 she married Mr. William Radcliffe, a student of law, who afterward became the editor and proprietor of "The English Chronicle," a weekly newspaper. Her first novel, "The Castles of Athlin and Dunbayne" (1789), gave little indication of her future powers, though it possessed the wild and improbable plot and the unnatural characters which distinguish her later writings. The "Sicilian Romance" (1790) is much better, and the "Romance of the Forest" (1791) is sufficient of itself to place her at the head of all writers of melodramatic romance. "The Mysteries of Udolpho" (1794) is generally regarded as her masterpiece. About the time this work was produced she made a tour through Germany, and in 1795 published her "Journey through Holland," &c., with some observations on the lake district of England. Her last novel, "The Italian," which deals with racks, tortures, dungeons, confessionals, monks, and inquisitors, appeared in 1797. One of her peculiarities is the care with which toward the close of her stories she usually explains all their mysterious incidents by natural and puerile agencies. A posthumous romance, "Gaston de Blondeville," was edited by Thomas Noon Talfourd (1826); and a collection of her poems, of which there are many scattered through her novels, appeared in 1834.

RADCLIFFE, John, an English physician, born in Wakefield, Yorkshire, in 1650, died Nov. 1, 1714. He was graduated at University college, Oxford, in 1691, studied medicine, and in 1675 began to practise in Oxford. In 1682 he received the degree of M.D., and in 1684 removed to London, where he soon acquired an extensive practice. He was appointed principal physician to the princess Anne in 1686, and in 1713 was elected to parliament by the town of Buckingham. Many anecdotes are recorded of his wit and rudeness of speech, which sometimes verged upon brutality. He was sent for to attend Queen Anne when she lay at the point of death; but knowing the case to be desperate, and being himself ill, he did not go. The feeling this excited against him is thought to have hastened his death. He bequeathed nearly his whole fortune to public uses, dividing it mostly between University college, Oxford, and the foundation at Oxford of a library with especial reference to medical science. This is known as the Radcliffe library.

RADETZKY, Joseph Wenzel, count, an Austrian general, born at Trzebnitz, Bohemia, Nov. 2, 1766, died in Milan, Jan. 5, 1858. He entered the Austrian army in 1784 as cadet in a regiment of Hungarian cavalry, and served in the campaigns of 1788–'9 against the Turks, and of 1792–'5 against the French in the Netherlands and on the Rhine. In 1796 he was aide-de-camp of Beaulieu in the army of Italy, and on May 29 was raised to the rank of major and commander of the pioneer corps. On the renewal of the war in 1799 he again served in Italy as aide of Melas, and for his ability and gallantry was made lieutenant-colonel. Recalled from Italy in Sept. 1800, he was placed at the head of the regiment of Archduke Albert cuirassiers, and with them was engaged in the battle of Hohenlinden. In 1805 he was made a major-general, and acted under Davidovitch in Italy. In the campaign of 1809 he commanded the 5th division of the army, and for his great
services, especially at the battle of Wagr
raised to the rank of lieutenant field
After the peace he was made chief of t
termaster-general's staff, and councill
minister of war, in which capacity h
large share in the reorganization of t
In the campaigns of 1813–'14 and 1815
chief of the staff of Field Marshal Sch
berg, participated in the battle of K
success of which was in great measure
his conduct, and drew up the plan of the
of Leipsic, in which he was severely w
After the close of the war he was sta
Oedenburg, subsequently in Buda, and

having a short time previous been m
eral of cavalry. There he remained un
when he was sent to Italy to take comm
the Austrian troops in that country.
1836 was raised to the dignity of field
It was here that he made himself m
cially famous by his conduct in suppr
Italian rebellion which broke out in 18
news of the revolution in Paris and th
throw of the government at Vienna
ately stirred up an insurrection in Mila
from March 18 to March 23 combats
the Austrian troops and the insurgents
stantly took place in the streets. On th
mentioned day Radetzky, finding his
worn out and overborne, evacuated Milan
began his retreat to Crema. Nothing da
by an equally successful outbreak in V
he hoped to maintain himself on the li
the Adda; but the spread of the insurr
throughout the north of Italy, and the ju
of the revolutionists with the army of C
Albert, king of Sardinia, which had bee
preparing for an attack on the Aust
rendered it necessary to retreat behind
Mincio, head-quarters being established at
rona. The advance of Charles Albert at
head of a large army compelled him to r
behind the Adige. Here an indecisive
was fought at the village of Santa Lucia
May 6, and on the arrival of the Aust
reserve he endeavored, but in vain, to raise
siege of Peschiera, closely invested by
troops of the king of Sardinia. The fall of
fortress on May 31 rendered his position exc
ingly critical, and his embarrassment was
further increased by the progress of the rev
tion in Vienna. In this situation the gener
ship of Radetzky showed itself in a m
marked manner. Feigning a general retr
he took the road to Vicenza, reduced that
Treviso, and Padua, thus securing his rear, and
rapidly returned to Verona. After a short de-
lay offensive operations were begun on b
sides. The victory of Custozza (July 25) for
the Piedmontese to retreat, and from this ti
the success of the Austrians was assured. M
capitulated on Aug. 6, and an armistice of 6
weeks was agreed upon between Sardinia
Austria. Charles Albert having resumed h
tilities, Radetzky invaded Piedmont, and

March 23, 1849, a battle took place at Novara between the contending forces, in which the Austrians were entirely victorious. The result of this conflict decided the war, and from this point Radetzky marched against Venice, which after a protracted siege finally surrendered, Aug. 28. Radetzky was made governor-general and military commander of the whole country, the duties of which situation he performed with zeal and unmitigated rigor. When war was imminent between Austria and Prussia in 1850, he was called to Vienna to prepare the plan of the campaign, but soon returned. In 1856, at the age of 90, he was released at his own request from his command, the duties of which he had become too feeble to discharge. He bore the reputation of a brave soldier and a consummate tactician, and was decorated with the insignia of nearly all the military orders in Europe. His only surviving children are the count Theodore de Radetzky, a colonel in the Austrian service, and the baroness Wenkheim.

RADISH (Lat. *radix*, root), the name of a salad plant, a native of China, belonging to the natural order of *cruciferæ*, which comprises a great number of useful species, all distinguished by the form of their flowers. The petals are 4 in number and arranged crosswise, the stamens 6, the 2 lower shorter, and the fruit either a flat and circular, or else a long, tapering, cylindrical, and jointed pod. The radish was introduced into England during the 16th century, 4 sorts being cultivated by Gerard in the latter part of the reign of Queen Elizabeth. The stem of the garden radish (*raphanus sativus*, Linn.) grows 3 to 4 feet high, and branches outwardly; its leaves are lyrate, sublyrate, and rough; its flowers are white tinged with purple; its pod uneven, tapering to a point, of 2 or 3 cells, and as long as the stalk. In shape the root is either fusiform or globular. As this is usually eaten in a raw state, it is desirable that it should have a crisp and clear flesh, which can be produced by growing rapidly. Sometimes however the root is boiled and served like asparagus. The young leaves make a very good pot herb when boiled, and the tender pods are employed in making pickles. There are a great many varieties and sub-varieties suitable to every season of the year. Those called spring and summer kinds may be brought forward early by forcing in hot-beds or sowing in frames. The autumn and winter kinds are sown in July and taken from the ground before the frosts spoil them, and stored away like carrots. When cultivated in the open air in private gardens, a warm, moist, good, well pulverized soil, that is free from stones, should be selected, and the seed sown in drills; or the seeds may be sown between the rows of asparagus beds, and when the young plants show the rough leaves they should be thinned and kept clear of weeds. If continuous crops are needed through the season, renewed sowings every fortnight may be resorted to. The following names indicate some of the best kinds of fusiform radishes, viz.: *early frame, short top*, long salmon, long purple, long white, &c. The globular are known as *scarlet turnip*, white Dutch turnip, purple turnip, &c.; the autumn radishes are sub-varieties of the black Spanish radish, the leaves of which are long and spreading, the root of an oval shape and of large size, its color black, its flesh solid, white, and of a hot flavor. There are several kinds of this in much esteem as being more or less hardy, of a more pungent or of a milder taste, and of different color of the skin. A tendency in all cruciferous plants to run into each other or hybridize, suggests the importance of keeping the sorts apart, if pure varieties are desired. —A distinct variety known as oil radish (*R. s. oleifer*, De C.), growing 6 to 24 inches high, is very much branched, with abundance of pods, from the seeds of which is expressed an oil similar to that of the rape, but not so readily obtained. It is however extensively cultivated in China for this purpose. The tree radish (*R. caudatus*, Linn.), a native of Java, is remarkable for the length of the pods, which measure more than the plant. The roots of the sea radish (*R. maritimus*, Smith) are preferred to those of horse radish for pungency; its leaves are liked by cattle. In the United States the radish shows a tendency to become naturalized, while the charlock or wild radish (*R. raphanistrum*, Linn.) is a troublesome weed.

RADNORSHIRE, a county of S. Wales, bounded N. E. by Montgomery, N. by Shropshire, E. by Hereford, S. by Brecknock, and W. by Cardiganshire; area, 425 sq. m.; pop. in 1851, 24,716. The chief towns are Presteigne, Knighton, Radnor, and Rhayader. The Wye and its tributary the Elan are the principal rivers. The surface is mountainous, the highest point being 2,163 feet above the sea; but the S. E. part is in general level. A great portion of the county consists of common bog and moor land. Numbers of small ponies are reared. The county contains many remains of antiquity. It originally formed part of the territory inhabited by the Silures, and, after its subjugation and ultimate abandonment by the Romans, was included in one of the petty principalities into which Wales was divided. It was formed into a county in the reign of Henry VIII. The county returns one member to parliament, and one for the principal towns.

RADOM, a government of Russian Poland, separated W. and N. from the government of Warsaw by the Pilica, and E. from that of Lublin and S. from Galicia by the Vistula, and with its S. W. corner bordering on Prussian Silesia; area, about 6,000 sq. m.; pop. 950,000. It is drained by the affluents of the Pilica and Vistula. The soil is diversified, and the surface the most elevated in the kingdom of Poland, being slightly mountainous in the S. E. part. The capital, Radom, is situated in the N. E. part on a small tributary of the Vistula; pop. 8,000.

RADOWITZ, Joseph von, a Prussian general and statesman, born in Blankenburg, Feb. 6, 1797, died in Berlin, Dec. 25, 1853. He received his military education in Paris and in Westphalian schools, and on account of his proficiency in mathematics was appointed in 1813 an officer in the Westphalian artillery. At the battle of Leipsic he was wounded and taken prisoner. Upon the dissolution of the kingdom of Westphalia he entered the service of the elector of Hesse-Cassel, and partook in the campaign against France with the Hessian artillery. After the peace he was made teacher of mathematics and military science at the school of cadets in Cassel, but finally quitted the Hessian service for that of Prussia. There he became captain in the general staff, teacher of Prince Albert, in 1828 major, and in 1830 chief of the general staff of the artillery. By his marriage with the countess Maria von Voss, he became a member of the highest aristocracy of Prussia, and also a favorite of the crown prince, afterward Frederic William IV. In 1836 Radowitz was made minister plenipotentiary to the Germanic diet at Frankfort, but in 1839 the prospect of a war with France led to his recall to Berlin, and to his being sent to the court of Vienna. In 1842 he was made ambassador extraordinary and minister plenipotentiary to the courts of Carlsruhe, Darmstadt, and Nassau, and in 1845 was created major-general. After the revolution of 1848 he was elected to the Frankfort parliament, and there became the leader of the extreme conservatives. After the revolution he entered the Prussian cabinet as minister of foreign affairs, and the adoption by the king of his political views, which aimed at a consolidation of northern Germany under the lead of Prussia, led to a difference between that power and Austria, which in the autumn of 1850 came near leading to an open war. At length Prussia retreated from its position, and Radowitz left the ministry. In Jan. 1851, he retired to Erfurt, and in 1852 was recalled by the king of Prussia and made director of military studies, but took no part in political life. He wrote on mathematical, military, and political subjects. His "Collected Works" appeared in Berlin in 5 vols. in 1852–'3.

RADZIWILL, the name of one of the oldest and most distinguished princely families of Lithuania. The first of the family appears in 1405 as marshal of Lithuania, and in 1518 the emperor Maximilian I. made the palatine of Wilna and chancellor of Lithuania, Nicholas III. Radziwill, a prince of the empire; and in this station he was confirmed by Sigismund I., king of Poland. When this line died out, the same honor was conferred upon the members of another branch, Nicholas the prince of Birze and Dulimki, and Nicholas IV. and John, princes of Olyka and Nieswiez; and from Nicholas IV., surnamed the Black, who is renowned as a promoter of the reformation in his country, and died in 1565, the present house is descended. Many of the family have made themselves widely known, but the most guished in later times are the three ing. I. **Anthony Henry**, prince of O. Nieswiez, born June 13, 1775, died lin, April 7, 1833. He married in 1 only daughter of Prince Ferdinand of sia, and became in 1815 Prussian gover the grand duchy of Posen. He was guished for his acquaintance with math and music, and the music to which he poetry of Goethe's "Faust" gained hi reputation. His two sons are now in Prussian service. II. **Michael Geron**, b of the preceding, born Sept. 24, 1778, d 21, 1850. He served under Poniatowski Kosciuszko (1794), and Dombrowski and in the campaign of 1812 against commanded a regiment in the grand ar Smolensk and in the battles of Vitepsk a lotzk he manifested such daring coura Napoleon made him a brigadier-gene the Polish revolution of 1830–'31, when picki had laid down the dictatorship, h appointed commander-in-chief in Jan. 18 he distrusted his own abilities, and the of the battles of Dobre, Grochow, and which followed, belongs more to his subor than to himself. At his own wish, on F Skrzynecki was made commander, and will entered the ranks. After the capt Warsaw he was conveyed into the inter Russia and there held until 1836, and after time lived in Dresden. III. **Leo**, nephew preceding, born March 10, 1808, was an in the Polish guard at the outbreak of th lish revolution of 1830–'31, but remained ful to Russia, and during the campaign served against his countrymen. As a re he was promoted in the army, and when in he married the princess Sophia Uronssoff ceived the confiscated estates of his uncle chael. His property, now immense, was v at 10,000,000 rubles. In Aug. 1849, he sent to Constantinople on a special missi obtain from the Porte the surrender of Hungarian refugees who had fled to Turkey.

RAEBURN, Sir Henry, a Scottish pai born in that part of Edinburgh formerly Stockbridge, March 4, 1756, died July 8, In early life he was apprenticed to a goldsm but evincing a great taste for art he was abled to cancel his articles, and to comme the practice of portrait painting in Edinbur where he soon became a rival of David Mar who then stood at the head of this branch the art. Subsequently, by the advice of Joshua Reynolds, he made a visit to Rom Returning to Edinburgh in 1787, he at became the leading portrait painter of th Scottish metropolis, a supremacy which h maintained until the close of his life. Amo his sitters were Sir Walter Scott, of whom h painted several portraits, Henry Macken Dugald Stewart, Lord Eldin, George IV., Pro fessor Playfair, Dr. Hugh Blair, Jeffrey, A son, and many others distinguished in liter er and in political life. In 1814 he was ected an associate and in 1816 a member of e royal academy; and in 1822 he was knight- by George IV.

RAFFAELLE. See Raphael.

RAFFLES, Thomas, an English dissenting ergyman, born in London, May 17, 1788. e studied theology at Homerton college near ondon, and in 1809 was ordained minis- e of the Congregational church at Hammer- ith. Here he remained 8 years, at the end which time he was called to take charge Great George street chapel in Liverpool. e has written a number of popular works, mong which are some poems, a memoir of is predecessor the Rev. Thomas Spencer, d "Letters during a Tour through some part France, Savoy, Switzerland, Germany, and e Netherlands" (1817). He has also pub- shed sermons, and a large number of fugi- ve articles. He retired from the pulpit in ec. 1860.

RAFFLES, Sir Thomas Stamford, an Eng- sh official, born at sea, off Jamaica, July 5, 781, died July 5, 1826. He was an assistant erk in the India house at the age of 15, and 1805 was appointed under secretary to the ew government formed by the East India ompany at Penang. He afterward became hief secretary; but intense application to busi- ess affected his health, and in 1808 he was ompelled to go to Malacca. In 1809 he pub- shed an essay "On the Malay Nation." It as by his advice that the expedition was fitted ut against Batavia in 1811, and when that lace was captured he was appointed lieutenant- overnor of Java and its dependencies. He eld this office for 5 years, during which slavery as abolished; and upon his return to England e published a "History of Java" (1817). In 818 he was made lieutenant-governor of Fort Marlborough, the seat of the English govern- ent at Bencoolen, Sumatra, and remained 6 ears in this position, emancipating the slaves ere also. He established the British settlement t Singapore, and founded a college there for he encouragement of Anglo-Chinese and Malay terature. The state of his health compelled im in 1824 to resign and return to England, where he founded the present zoological so- iety, of which he was the first president. His "Life and Remains" were edited by his widow 4to., London, 1830).

RAFINESQUE, C. S., an American botanist, orn in Galata, a suburb of Constantinople, in 784, died in Philadelphia, Sept. 18, 1842. His ather was a merchant in the Levant from Mar- eilles, and the son was carried to that city when 7 years of age, thence taken to Italy, and, fter residing in various cities in the northern art of that country, came in 1802 to America. Having collected a large number of botanical pecimens, he returned in 1805 to Leghorn, whence he went to Sicily, where he remained 0 years. While there he published a work in French, entitled "The Analysis of Nature." Sailing for New York in 1815, he was shipwrecked on the coast of Long Island, and lost, as he says, "my fortune, my share of the cargo, my collections and labors for 20 years past, my books, my manuscripts, my drawings, even my clothes." He became teacher in a family, and in 1818 made a tour to the West, and was for a time professor of botany in Transylvania university, Lexington, Ky. Finally he settled in Philadelphia, and established in 1832 a periodical called "The Atlantic Journal and Friend of Knowledge, a Cyclopedic Journal and Review," which, according to the prospectus, was to "contain every thing calculated to enlighten, instruct, and improve the mind." Only 8 numbers were published. In 1836 appeared his "Life of Travels and Researches," giving an account of the places he had visited. He also wrote several botanical works.

RAFN, Carl Christian, a Danish archæologist, born in Brahesborg, Island of Fünen, Jan. 16, 1795. He was educated at the university of Copenhagen, of which in 1821 he was made an assistant librarian; and while in that position he undertook a general revision of all the Icelandic and Norwegian manuscripts yet unpublished, belonging to the collection. Through his exertions the "Society for Northern Antiquities" was founded, the principal object of which was to publish those manuscripts which could throw any light on the obscure passages of Scandinavian history. It has already published about 70 volumes on the history and antiquity of the North. The work which excited the most attention was the *Antiquitates Americanæ, sive Scriptores Septentrionales Rerum Ante-Columbianarum in America* (Copenhagen, 1837), prefaced by a summary in English, in which he attempted to prove that the Scandinavians discovered America in the 10th century, and that from the 11th to the 14th they made frequent voyages to the western hemisphere, and effected settlements in what is now Massachusetts and Rhode Island. An important sequel to this work is the "Historical Monuments of Greenland" (3 vols., Copenhagen, 1838–'45). Of his *Antiquités Russes* 2 volumes appeared in 1850–'52. As secretary of the society for northern antiquities he has had much to do with preparing its various publications for the press, and has also been the translator and editor of other works.

RAGLAN, James Henry Fitzroy, baron, an English general, born Sept. 30, 1788, died in camp before Sebastopol, June 28, 1855. He was the 8th and youngest son of the 5th duke of Beaufort, and grandson on his mother's side of Admiral Boscawen. He was educated at Westminster school, and at the age of 16, being then known as Lord Fitzroy Somerset, entered the 4th regiment of dragoons as ensign. In 1805 he became lieutenant, in 1807 accompanied Sir Arthur Paget in the embassy to Constantinople, and subsequently became attached to the staff of the duke of Wellington as aide-de-camp and military secretary. In this position he participated in all the duke's engagements during the peninsular war, manifesting great intrepidity on various occasions, especially at Salamanca, Vittoria, Orthez, and Toulouse. At Busaca he was wounded, and at the storming of Badajoz he was one of the first to enter the town. At Waterloo he lost his right arm. In return for his services he was made colonel and knight commander of the bath. In 1814 he was for a short time secretary of embassy at Paris; from January to March, 1815, he acted as minister plenipotentiary, and subsequently he was secretary again until 1819, when he became military secretary to the duke of Wellington, and held this post until 1827, when in the same capacity he followed the duke to the horse guards. From 1818 to 1826 he represented the borough of Truro in parliament, where he acted with the moderate tories. After the death of the duke of Wellington he was made master-general of the ordnance, and elevated to the peerage (1852), with the title of Baron Raglan. When the war with Russia broke out, he was appointed by Lord Aberdeen to command the army sent to the East, and promoted to the rank of field marshal. In March, 1854, he left England, in September reached the Crimea, and on Sept. 20 fought in conjunction with Marshal St. Arnaud the battle of the Alma. During the following winter the allied troops perished in large numbers in the trenches before Sebastopol, and his anxiety in regard to the condition of the men and the attacks of the English press upon his military movements weighed heavily upon his spirits. In this state of mind he was seized with the cholera, and soon died. His body was taken to England and buried in Badminton church, Gloucestershire. A pension of £1,000 was settled for life upon his widow, and £2,000 upon his son.

RAGUET, Condy, an American merchant and political economist, born in Philadelphia, Jan. 28, 1784, died there, March 22, 1842. He was of French descent, was educated at the university of Pennsylvania, and for 18 months after his graduation pursued the study of law; but the death of his father leaving him dependent upon his own exertions, he entered the counting house of a merchant, and at the age of 20 was sent to St. Domingo as supercargo of a vessel. There he spent 4 months, and on his return published a work entitled "A Short Account of the Present State of Affairs in St. Domingo." After a second voyage to the same island in 1805, when he remained there 8 months, he published "A Circumstantial Account of the Massacre in St. Domingo." In 1806 he went into business on his own account, was highly successful, and became manager or president of several important commercial institutions. In 1815 he was elected a member of the lower house of the Pennsylvania legislature, and subsequently of the senate, and in 1822 was appointed by President Monroe consul at Rio Janeiro. Not long after he negotiated a commercial treaty with Brazil, and by President Adams was made chargé d[illegible] to that country. There he remained 5 y[illegible] and upon his return to the United Stat[illegible] several journals devoted to free trade d[illegible] He published "Principles of Free Trad[illegible] Philadelphia, 1835), and a treatise "[illegible]rency and Banking" (1839), which was [illegible]lished the same year in England, and wa[illegible] translated into French.

RAGUSA (Slav. *Dubrovnik*), a forti[illegible] port city of Austria, capital of a distric[illegible] same name, province of Dalmatia, situat[illegible] small peninsula of the Adriatic, abou[illegible] N. N. W. from Cattaro, in lat. 42° 38′ [illegible] long. 18° 7′ E.; pop. 6,000. It is buil[illegible] at the foot and partly on the declivity of [illegible] Sergio, so that the upper streets are co[illegible] with the lower by steps. The harbor [illegible] S. is small and exposed to the sirocco; [illegible] the N. side of the peninsula, 2 m. distant [illegible] harbor of Gravosa, which is large en[illegible] admit ships of the line.—Ragusa was f[illegible] in the 7th century, being peopled by Sla[illegible] Italian settlers, and formed down to [illegible] times an aristocratic republic, which flo[illegible] successively under Greek, Venetian, Hun[illegible] and Turkish protection. After the pea[illegible] Presburg in 1805 it was occupied by the Fr[illegible] In 1806 the Montenegrins and Russians o[illegible] its territory, and besieged the French wi[illegible] walls. It was subsequently created by [illegible]leon a dukedom for Marmont, and incorp[illegible] with the new kingdom of Illyria, with [illegible] in 1814 it came into the possession of A[illegible] The city has been frequently injured by [illegible]quakes. The latest earthquake was th[illegible] 1850.

RAHBECK, Knud Lyne, a Danish a[illegible] born in Copenhagen, Dec. 18, 1760, died A[illegible] 22, 1830. He was educated at the univer[illegible] of Copenhagen, where in 1790 he became [illegible]fessor of æsthetics. From 1798 to 1805 h[illegible] teacher of history in Christian's institute, f[illegible] 1806 to 1816 lectured to actors on the dra[illegible] art, and in 1809 became an active memb[illegible] the managing committee of the theatre. I[illegible] 1816 he was again a teacher in the univers[illegible] He was the most active and influential of th[illegible] literary men of Denmark, and wrote pla[illegible] tales, lyric poems, essays, and translati[illegible] The *Danske Tilskuer* ("Danish Spectat[illegible] 1791–1806), an imitation of Addison's "Spe[illegible]tor," is generally regarded as his best work.

RAHWAY, a city of Union co., N. J., on the Rahway river, 5 m. from its mouth, and [illegible] the New Jersey railroad, 19 m. W. from New York and 9 m. W. from Newark; pop. in 18[illegible] 7,130. It was formerly divided by the riv[illegible] into Upper Rahway, in Rahway townsh[illegible] Essex co., and Lower Rahway (form[illegible] Bridgeton), in Woodbridge township, Middle[illegible] co.; but it has now been consolidated and [illegible] in Union co., which has recently been formed. There are 87 different manufacturing est[illegible]lishments, producing annually to the value of $1,552,700; of these, 39 manufacture carria[illegible] the annual value of $902,000, and 5 clothing the amount of $920,000. It contains the lumbian academy, the Rahway female insti-te, 6 public schools, a bank, 3 newspaper ices, and 16 churches, viz.: 1 African, 1 Bap-t, 1 Episcopal, 2 Friends', 1 German Reformed, Methodist, 2 Presbyterian, and 1 Roman tholic. The river, a very small stream, will mit of the passage of vessels not exceeding or 60 tons. The settlement of this town s commenced about the year 1720.

RAIKES, Robert, an English philanthropist, e originator of Sunday schools in England, rn in Gloucester in 1735, died April 5, 1811. e received a liberal education, became asso-ated with his father as publisher and editor the "Gloucester Journal," and eventually cceeded to the business. The state of the unty bridewell attracted his attention, and made a strong and in some degree success-l effort to ameliorate the physical condition offenders of all grades confined there. But most earnest efforts were excited in favor the multitudes of poor children whom he und in the streets of the town abandoned to e practice of every vice. In 1781 he hired oms for Sunday schools, employed poor wo-en at a shilling a day to teach the children read, and was successful in inducing them attend. The movement became popular, d in a short time Sunday schools were estab-shed in all the larger towns of England.

RAIL, the proper name of the *rallinæ*, a sub-mily of wading birds of the family *rallidæ*. e genus *rallus* (Linn.) is characterized by a ll longer than the head, nearly straight and ender, with the culmen a little curved, and p obtuse and slightly notched; nostrils in a embranous groove which extends for ⅔ of the ll; wings short, with the 2d and 3d quills ual and longest; tail short and rounded; rsi shorter than the middle toe, covered with ansverse scales; toes long and slender, free the base, the hind one short; claws short nd sharp; forehead, as in all the sub-family, athered to base of bill, the culmen parting e frontal feathers for a short distance and in n angle. There are about 20 species, found n all the temperate parts of the globe, resem-bling each other in habits and much alike in lumage; they inhabit marshes and borders of vers, among reeds and aquatic plants, which heir long toes, sharp claws, and compressed odies enable them to climb and run over or etween with great facility; the flight is awk-ward and slow, with the legs hanging down, nd for short distances only except during mi-gration; they are good swimmers and divers, nd very rapid runners on the ground. Their od consists of worms, slugs, crustaceans, tad-oles, insects, leaves, and seeds of water plants; e nest is made of coarse grasses, and placed n retired marshes, and the eggs are 10 to 12. hey are very generally called marsh hens, as hey resemble domestic fowls in their manner f carrying the head, in some of their habits, and in their cackling notes. The largest of the North American rails, and one of the handsomest of the genus, is the red-breasted rail or the fresh water marsh hen (*R. elegans*, Aud.); it is about 19 inches long, the bill 2, and 24 in alar extent, with a weight of about 1¼ lbs.; the color above is olive brown, with longitudinal stripes of brownish black, especially on the back; throat and lower lid white; neck before and breast rufous chestnut; sides, lower parts, and under tail coverts with transverse bands of brownish black and white; upper wing coverts reddish chestnut, the under black with white lines. It is found in the middle and southern states on the Atlantic coast, probably extending across to the Pacific, and chiefly on the margin of fresh waters; it begins to breed in the southern states about the middle of April in its favorite marshes, surrounded by alligators and myriads of frogs, in places almost inaccessible and exceedingly unhealthy to man; the young leave the nest as soon as born, safe from man, but not from minks, wild cats, raccoons, owls, snakes, turtles, and other carnivorous animals. The females are like the males, but smaller; they do not take to the water willingly, and are rather poor divers; the flesh is good, especially in autumn, and their eggs are said to be delicious. The clapper rail or salt water marsh hen (*R. crepitans*, Gmel.) is about 14 inches long, with an alar extent of 20, and a weight of ¾ of a lb.; the adult plumage is considerably like that of the last species, but the upper parts have a light ashy olive tint, and the neck and breast are more yellowish. It is abundant from New Jersey to Florida, extending also to South America, and is rarely found far from the sea; the nest is deep and funnel-shaped, made of marsh plants and fastened to reeds above the ordinary high tide level; incubation lasts 14 days; the eggs are also excellent, and are collected by hundreds in New Jersey toward the end of spring. Following the edge of the tide, it searches among the reeds for small crabs (fiddlers), mollusks, the *fry* of fishes, aquatic insects, and the seeds of water plants; it makes a loud cackling noise; it is not a rapid swimmer, but is a good diver, and a very swift runner either on the ground or on floating weeds; its flight is slow and generally straight; though esteemed as food, other species are more sought after, especially the sora, in the middle states. The Virginia rail (*R. Virginianus*, Linn.) is about 10 inches long, with an alar extent of 14; it is like the others in form, and resembles *R. elegans* in color, hardly differing from it except in size. It is found throughout the temperate regions of North America from the Atlantic to the Pacific, most abundantly along the margins of rivers and bays on the Atlantic, migrating south in autumn; it is a very rapid runner and good swimmer, feeding both on salt marshes and fresh meadows, by day and night. It breeds from the beginning of March to the middle of June, according to latitude; like the other spe-

cies it is a good ventriloquist, seeming often to be far off when close at hand; the flesh is good eating in autumn and winter. The European water rail (*R. aquaticus*, Linn.) is fulvous brown spotted with black above, bluish ash below, and barred black and white on the sides. The habits are the same as in other species; the flesh is esteemed, though having rather a marshy flavor.—The genus *ortygometra* (Linn.) has been subdivided into *porzana* (Vieill.) and *crex* (Bechst.). In *porzana* the bill is shorter than the head, the primaries longer than the tertiaries, the tail short, and the legs robust; there are about 20 species in the temperate regions of the globe, with habits similar to those of *rallus*. Among the North American species may be mentioned the Carolina or sora rail (*P. Carolinensis*, Vieill.), so well known and so abundant as to be called "the rail" in the middle states; the length is about 9 inches and the alar extent 14; the color is greenish brown above, with longitudinal lines of black; behind the eyes, sides of neck, and breast bluish ashy, with round white spots on the latter; middle of abdomen white. It occurs throughout temperate North America on both shores, migrating southward in winter; it is rarely seen east of New York, though capable of rapid and protracted flight; in autumn it is abundant in the rice fields and fresh water marshes of South Carolina, skulking among the grasses and reeds in search of food, climbing with ease to the top of plants when forced by the tide; thousands are shot at this season on the James and Delaware rivers from boats, near the height of flood tide, and usually singly; sometimes they are knocked down by poles when dazzled by a bright light in the bow of a canoe. It is semi-nocturnal in habit; when migrating the flight is low and in compact flocks; instinct teaches them the last moment at which they can remain in the autumn, all migrating in a single day or night, whence the once prevalent idea that they dived under the mud to pass the winter. The little black rail (*P. Jamaicensis*, Vieill.) is about 6 inches long, the smallest of the North American species of the family; the head and lower parts are slate-colored, nearly black on the top of the head; abdomen banded with white; upper parts brownish black with white stripes, and reddish chestnut on the upper back; the young are wholly bluish black. It is rare on the continent, but more abundant in the West Indies; it is highly prized by collectors. The yellow-breasted rail (*P. Noveboracensis*, Vieill.) is about 7 inches long and 13 in alar extent; the color is ochre yellow above, with brownish black and white stripes; neck and breast tinged with reddish, middle of abdomen white, sides banded with reddish brown and white; under tail coverts rufous, white-spotted, and under wing coverts white. This pretty bird, resembling a young chicken, is found, though not abundantly, in damp meadows in the eastern and southern states; it approaches in habit the corn crake and in some respects the European quail, and
was regarded by Audubon as one of th
necting links between land and water
the flesh is delicate.—In the genus *crex*
the bill is conical, shorter than the he
the whole appearance and habits are m
those of gallinaceous birds. The E
land rail or corn crake (*C. pratensis*,
is about 10 inches long; the genera
above is blackish brown, with lighter
but without white spots; grayish belo
lives and nestles in fields and meadows, r
with great rapidity; its cry resembles the
lables "crex, crex," causing a disagr
rattling in the throat, whence the name
derived from the French *râle*, accordi
Buffon. It is a solitary bird, remainin
cealed during the day, and seeking its
morning and evening; it is a northern
migrating to central Europe in spring a
turning in October; the French call it
of the quails" from its coming and goin
the same time with that bird; in sum
seems to be a constant visitor to Gre
and is occasionally seen on the E. coast
United States; it feeds principally on
insects, and worms.—The following gen
less known. *Aramides* (Puch.) has a
dozen species in the warmer parts of
America, inhabiting thick woods and per
at night; the notes of one species (*A.*
nensis, Gmel.) are so loud and clear that
may be heard for more than a mile; th
large bird, 18 inches long with a bill of
es; it feeds on small mammals, birds, fish,
insects, and fruits, and is useful about
by destroying rats and mice. *Eulab*
(Gould) is found in Australia and the M
cas; there are about half a dozen spe
Corethura (Reich.) has about 30 species in
parts of the globe.

RAILROAD, or RAILWAY, a road constr
of two parallel bars of iron, upon which
wheels of carriages run. Various devices
been employed from the time when whee
riages were first used for facilitating their m
ment over the ground. These have been, h
ever, mostly limited to the smoothing and h
ening of the road bed. The Egyptians lear
in moving the great stones for their pyram
from the quarries, the advantage of solid tr
ways, and the remains of such formed of blo
of stone are said to have been found on the
of the great roads they constructed for th
purpose. The ancient Romans made an ap
proach to the invention of railroads in the Ap
pian way, which was formed of blocks of sto
closely fitted together, their surface presen
a smooth and hard track for the wheels. In
modern times such tracks have been made in
several European cities, as Pisa, Milan, Lond
&c. The first instance of the use of rails ap
pears to have been some time previous to the
year 1676 at the collieries near Newcastle
upon-Tyne, England. At that time, as narrat
ed by Roger North in his life of Lord Keepe
North, the coals were conveyed from the mine

the banks of the river "by laying rails of timber exactly straight and parallel; and bulky carts were made with 4 rollers fitting these rails, whereby the carriage was made so easy that one horse would draw 4 or 5 chaldrons of coal." This great improvement was slowly appreciated, and its adoption was for a long time confined to the coal districts of Northumberland and Durham. Changes, however, were introduced in the construction of the track, and, according to a description of the road made about the year 1765, it had already assumed the principal features of railroads, even including the use of flanges upon the wheels, but not an iron surface for the wheels to roll upon. The following was the method of construction. The road being brought to as uniform an inclination as practicable, squared blocks of wood, called sleepers, about 6 feet long, were laid 2 or 3 feet apart across the track. Upon these two long strips of wood, 6 or 7 inches wide and 5 inches deep, were fastened by pegs parallel to each other and about 4 feet apart, and these lines were thus extended the full length of the road. The track was then filled in with gravel, ashes, or other road material. Wagons carrying 2 or 3 tons of coal were used to run on the track, their wheels provided with flanges which pressed against the edges of the rails, and prevented their slipping off. The structure was improved by securing a second set of rails upon the top of the first, thus increasing the facility of removing and replacing the wearing surface in any portion without affecting the remainder of the road. Even at this time straps of iron were nailed upon the rails to diminish the friction wherever the ascent was steep or sharp curves made the draught more difficult. The next improvement was introduced in 1767 at the iron works of Colebrook Dale, at a time when pig iron was very cheap, and the metal might advantageously be applied in the way of experiment to new uses. The proprietors made iron bars to take the place of the upper rail of the road, casting them 5 feet long, 4 inches wide, and 1¼ inches thick, with holes for the spikes by which they should be secured to the lower rail. Some time after this, about the year 1776, the iron rails were cast with a perpendicular ledge upon the outer edge, in order to keep the wheels from running off the track; and after a time the ledge was transferred to the inner side of the rail. These were called tram roads and plate roads, the former name being derived from a Mr. Outram, who was connected with the collieries. Tram is also the name of the wagons run on these roads. The success of this improvement led to its general introduction in mines, and for a long period the rails were made altogether of cast iron; but since the construction of the new machinery for rolling malleable iron, this has been in great measure substituted for it. The objection to tram roads is the liability of the rail to get obstructed with stones and dirt, and thus impede the progress and endanger the safety of the carriage. They moreover add unnecessarily to the weight of the rail. A great step in advance was made in 1789 by Jessop, who laid down at Loughborough cast iron "edge rails," of even surface at the top, the ledge being transferred round the edge of the wheel and forming a flange, which was kept above the ground by the elevation of the rail. The rails are said to have been set and bolted in cast iron chairs and on sleepers. The importance of these improvements, which comprised some of the essential features of modern roads, does not appear to have been immediately appreciated. Edge rails were again in use, however, in 1801 at the slate quarries of Lord Penrhyn, made of oval section with the longer diameter vertical. They were 4½ feet long, and each end terminated in a block of the shape of an inverted wedge, which fitted a cavity in an iron sill imbedded in the road. The tire of the wheel was hollowed out to fit the convex surface of the rail; but as the fit became too tight by wear, it was afterward found expedient to make the surface of the rail flat, and that of the wheel the same with a flange around each edge of it. So great an improvement was this, that it was found 10 horses could do the work that had employed 400 upon a common road. Edge rails were soon after introduced at the collieries in the north of England, and a new form was there adopted with the view of securing increased strength without proportional increase of weight. They were made thin, spreading in thickness at the top, and the under edge was curved, giving the greatest depth midway between the ends or points of support of the rail. This was known from its form as the "fish-bellied" rail, and long continued in use even after wrought iron rolled rails were substituted for those of cast iron. It was in 1808 that this improvement was introduced; but flat bars only could be used, and it was not until 1820 that machinery was constructed for rolling iron into suitable shapes for rails. The substitution was very important, as the cast iron rails could be made straight only 3 or 4 feet long, and consequently required frequent points of support, and the joints were numerous. The material moreover is brittle compared with wrought iron, and altogether unsuitable on this account for heavy loads and high speed. The motive power employed was almost exclusively that of horses. On inclined planes gravity was made use of for descending wagons, and these were sometimes made to draw up others by means of a rope passed around a wheel at the summit. —The possibility of constructing steam carriages had been suggested by Watt in the course of his early investigations of the properties and applications of steam; and in 1782 Oliver Evans of Philadelphia patented a steam wagon, the drawings and specifications of which were sent to England in 1787, and again in 1794-'5. A locomotive carriage was also patented in 1784 by Watt, and a non-condensing working model was constructed the same year by his assistant, Wm. Murdoch. In 1802 Richard Trevithick patented a high pressure locomotive engine, and in 1804 constructed one for the Merthyr Tydvil railway in S. Wales. Lightly loaded, it did very well upon a level surface or moderate grade; but more severely tasked, the wheels would slip round without advancing. A check was thus put upon their use until some method could be devised by which they might obtain a hold upon the track or otherwise push themselves forward. A rack laid along the side of the rail into which worked a toothed wheel fitted to the locomotive was tried in 1811 on a colliery line near Leeds, but the friction was too great, and it was abandoned. The next year engines were tried with 8 driving wheels for securing the required adhesion; and about the same time other engines were constructed with levers projecting behind and working alternately like the hind legs of a horse. In 1814 and 1815 engines with plain wheels were found to work successfully on some of the northern roads; but no other application was made of them than for transporting the coal and ore wagons of the mines. The first railroad opened for conveying passengers was the Stockton and Darlington road in 1825, and this was worked with horse power. The French engineer, M. Seguin, in 1826 successfully introduced locomotives upon the railways from Roanne to St. Étienne, and from St. Étienne to Lyons, and to Andrezieux; and in these he first constructed small tubes passing from the fire box to the chimney, an arrangement of the greatest importance for increasing the evaporative power of the engine, and which was adopted by Messrs. Stephenson and Booth in their engines. He also increased the draught of the fire by means of a ventilator, an effect which Robert Stephenson better accomplished in 1829 by the action of the steam. The Liverpool and Manchester road was commenced in 1825, and it was the intention of its projectors to run the carriages upon it at high rates of speed. To do this with horses was expensive, and to work it by steam power it was supposed that stationary engines would be required at short intervals along the road to draw the trains by ropes from one station to another. A premium of £500 was offered for the best engine—one that should not produce smoke, should draw 3 times its own weight at the rate of 10 miles an hour, should be supported upon springs, should not weigh more than 6 tons, or 4½ tons if it ran on 4 wheels only, and should not cost more than £550. In Oct. 1829, 4 locomotives were presented for trial, and the prize was awarded to the Rocket, weighing 4 tons 5 cwt., built by Messrs. Robert Stephenson and Booth, which ran at an average speed of 14 miles an hour, with a gross load of 17 tons, and under certain circumstances doubled this speed. The next year steam carriages were in regular operation upon this road. Thus was established a new system of locomotion, vastly exceeding in capacity all others before known, destined to be rapidly extended, and to exert an extraordinary and most beneficial influence upon human affairs. The [illegible] engine that determined the question of its use soon gave place to more powerful machines, till some of those employed upon the English roads have attained a weight exceeding [illegible] tons; on the great western line are some [illegible] tons, and on the Sœmering line of 48 tons, having 6 coupled wheels. The road upon which this great result was accomplished was laid with wrought iron rails of the "fish belly" form. Several of the curves or spans were included in each rail, and they were stiffened by projecting ledges or rims on the under side. Their weight was 33 lbs. to the yard; and they were supported in cast iron chairs, which were spiked down to square stone blocks between the spans, or at every three feet. The gauge or distance apart of the two rails was 4 feet [illegible] inches, which, having been afterward generally adopted in England, is considered as the national gauge. New roads were immediately projected in England, chiefly in the northern part, connecting together its principal cities, or adding to the numbers already constructed in the mining counties. The capacity of the locomotive was not however yet appreciated, and upon most of the roads it was considered necessary to build inclined planes for overcoming the ascents, and upon these employ stationary engines to draw the trains to the summit. Upon these and upon tunnels, both designed to reduce curvatures to the least possible amount, and also the grades upon the running portions of the roads, money was most freely expended; and as a measure of safety the more important roads were from the first built with double tracks.—The advantages secured by these improvements were too important to be overlooked in the United States. Before the application of steam to railroad purposes was established, a horse railroad was partially built in 1826 and completed in 1827, from the granite quarries of Quincy, Mass., a distance of 3 m. to the Neponset river. This terminated at the quarries with a self-acting inclined plane. The road was built upon granite sleepers 7½ feet long, laid 8 feet apart. The rails, 5 feet apart, were of pine, a foot deep, covered with an oak plate, and this with flat bars of iron. The second road was laid out in Jan. 1827, and was completed in May of the same year, from the coal mines of Mauch Chunk, Penn. to the Lehigh river, a distance of 9 m., and with the turn-outs and branches the whole length exceeded 13 m. From the summit within half a mile of the mines the descent to the river was 982 feet, of which 225 were included in a self-acting plane at the river, and 25 feet more in a shute by which the coal was discharged into the boats. The remainder was in a continual descending grade, down which the loaded wagons ran by gravity, one of them being appropriated to the mules by which the empty wagons were drawn back. The rails were of timber laid on wooden sleepers and strapped with flat iron. In other states at this time an extraordinary activity began to be aroused and measures set on foot to introduce the improved means of conveyance and transportation of freight upon the principal lines of communication. Charters were obtained in Massachusetts, New York, New Jersey, Pennsylvania, Maryland, South Carolina, and other states for numerous roads, some of which were designed upon a grand system, favored by the peculiar features of the country and the success which had attended the Erie canal and other works of internal improvement. The Delaware and Hudson canal company in 1828 constructed a railroad from their coal mines to Honesdale, the terminus of the canal; and had already commissioned Mr. Horatio Allen, who had gone in the autumn of 1827 to England for the purpose of investigating the railroads of that country, to purchase their railroad iron and 3 locomotives. One of the engines, built by George Stephenson at his works at Newcastle-upon-Tyne, arrived in New York in the spring of 1829, and was to be seen for some time in the yard of E. Dunscomb in Water street, its wheels raised above the ground and kept running for the gratification of those interested. Another engine, built by Foster, Rastrick, and Co., of Stourbridge, arrived soon after, and was put on the road the latter part of the summer of 1829. This was the first use of a locomotive in this country. It was an engine on 4 wheels, furnished with the multitubular boiler and the exhaust blast. In South Carolina operations were commenced in 1829 upon the road designed to connect Charleston with Hamburg on the Savannah river; and 6 m. were completed from Charleston in that year. It is a noteworthy fact that before the use of locomotives was established in Great Britain, or they were known in the United States, the directors of this road determined, under the advice of their engineer, Mr. Horatio Allen, as given in his communication to the board in November, 1829, to make them exclusively the motive power, and the road was constructed in such a manner as to be wholly dependent upon them, being built upon piles, often at a great height above the ground. The company offered a premium of $500 for the best plan of horse locomotive, and this was awarded to Mr. C. E. Detmold, afterward of New York, who constructed one with the horse working on an endless chain platform. It carried 12 passengers at the rate of 12 m. an hour. The same gentleman, in the winter of 1829-'30, made the drawings of the first American steam locomotive, called the "Best Friend," which was planned by Mr. E. L. Miller, then residing in Charleston, made by the Kembles at their shop in West street, New York, and placed on the road late in the summer of 1830. It was a small 4-wheeled engine with upright boiler and water flues close at bottom, and the flame circulating around them. It worked successfully for about two years, when it exploded, and was rebuilt with a flue boiler. Upon this road, in 1831, was first introduced on any railroad either abroad or in the United States the important arrangement of two 4-wheeled trucks for locomotives and long passenger cars. These were built from plans designed by Mr. Horatio Allen in 1830; and with no essential change his system of double truck running gear, including the application of pedestals to the springs, has ever since been adopted upon all the roads of the country.—Of the great railroad enterprises, one of the principal was the Baltimore and Ohio road, of which the first stone was laid on July 4, 1828, and which was gradually extended from the city of Baltimore across the Patapsco, and up this stream to Ellicott's Mills, 13 m. from Baltimore. It was thence projected to the Potomac at the Point of Rocks, 67 m. from the city, on the line of the Potomac valley, to the coal region of Maryland and to the Ohio river. The road was originally planned for horse cars only; but the successful introduction of steam locomotives in England encouraged the attempt to run them here, and in 1829 a small locomotive, built in Baltimore by Mr. Peter Cooper, was put upon the road, and by this and also by horses trains were regularly run in that year to Ellicott's Mills. From Jan. 1 to Sept. 1, 1831, the number of passengers transported was 81,905, beside 5,931 tons of freight. The road was constructed of longitudinal rails pinned down to the wooden or stone cross ties, which were imbedded in the ground, and upon the rails were fastened flat bars of iron ½ and ⅝ inch thick and 2½ to 4½ inches wide by spikes, their heads countersunk in the iron. This method, which was generally adopted upon the early American roads from considerations of economy, and with the view of extending the lines to the utmost limit of the capital provided, was soon found to involve great danger and consequent expense. The ends of the rails became loose, and starting up were occasionally caught by the wheels and thrust up through the bottom of the cars. It was found necessary to run the trains with great caution upon the roads thus constructed, and the passenger traffic was seriously diverted from those lines that had acquired a notoriety for "snake heads." In Aug. 1830, the Hudson and Mohawk railroad, from Albany to Schenectady, N. Y., 16 m., was commenced, a charter for which had been granted in 1826. In Oct. 1831, the number of passengers upon it was stated to be 387 a day, and in 1832 a locomotive with a load of 8 tons travelled on it at the rate of 30 m. an hour. Several other railroad enterprises were undertaken in the Pennsylvania coal region in 1830, and in the session of the legislature of 1830-'31 no fewer than 12 railroad companies were incorporated. In 1830 operations were commenced upon the Baltimore and Susquehanna railroad. In 1831 a road was completed on the S. side of the James river in Virginia, from Manchester, opposite Richmond, 13 m. up the river to the coal mines; and on April 16 of the same year the Lake Pontchartrain road in Louisiana, 4½ m. long from the lake to New Orleans, was opened. From this time these enterprises were multiplied with great rapidity. In Pennsylvania, it is stated, 67 railroads were in operation in 1832; and in that year were commenced the most important lines of Massachusetts and New Jersey. In a very short time the roads outstripped in length those of Great Britain, and have ever since far exceeded in numbers and extent those of other countries. They have however been planned and constructed in great measure independently of each other, without regard to any great system; and as the charters are granted by each state for the roads in its own territory, a single state has sometimes, by refusing to authorize the construction of a proposed road, succeeded in preventing the establishment of an important line, the opening of which, it was supposed, might injuriously affect the whole or a favored part of such state. This want of system is perceived and its evils are experienced in the various gauges adopted by different roads, rendering necessary frequent transshipment of passengers and freight. The early roads using English locomotives were constructed for a gauge of 4 feet 8½ inches, that being the chance width of the old tram roads of the north of England, and retained upon the newer roads. In the United States independent gauges were afterward introduced, as of 4 feet 10 inches in New Jersey and Ohio; 5 feet, which is the gauge of the Virginia and Tennessee road and other southern roads; 5 feet 4 inches, that of two roads in Ohio; 5½ feet, that of the Atlantic and St. Lawrence road, Maine, also established by law in Missouri, and afterward in Canada; and 6 feet, which is that of the New York and Erie road. In order that the business of the last of these roads might be brought to New York city through New Jersey on the line of the Paterson road, it was found necessary to add a third rail to the narrow track for the special accommodation of the Erie trains. Notwithstanding the original want of system, several important continuous lines have been developed, in part by bringing together detached and independent roads, and in part by the construction of long roads looking specially to this end. The first great lines were established to secure to the cities on the seaboard from which they emanated a larger share of the business from the western states. The advantage secured to Boston by the opening of the western road terminating at Albany, and taking thence into Massachusetts at all seasons, and especially in the winter when the Hudson river was closed, produce brought by canal and by the New York central roads from Buffalo, compelled New York to open a route direct from the city to Lake Erie; and the Erie road, commenced in 1833, was pushed forward to its completion, which however was not reached until 1851. The Housatonic road, though perhaps not built specially on this account, also benefited New York in winter, particularly in this competition with Boston. But before these enterprises were completed the latter city had furnished the means for opening the Michigan central, and extending it from Detroit to Chicago, that the products of the West might more readily reach Albany; and it was also sending out its arms toward the N. W., reaching the outlet of the great lakes at Ogdensburg, before this was connected by railroad with the metropolis of its own state. These enterprises stimulated Pennsylvania to perfect her line of communication between Philadelphia and Pittsburg, which from Harrisburg to Hollidaysburg was by canal, and thence over the Allegheny mountains by a succession of 5 inclined planes and intervening levels up the mountain on one side, then by a long level to the 5 inclined planes and levels which terminated below at Johnstown, where another canal took the boats that had been brought over the mountain in sections, and conveyed them to Pittsburg. The canals and inclined planes were done away with, and a continuous road was opened across the state. This has been made to connect at Cleveland on Lake Erie, with Chicago, and through Columbus and Cincinnati with the system of roads of Indiana and Illinois. Baltimore, feeling the effects of these advances, was impelled to push forward the Baltimore and Ohio road, which had long stopped in the Cumberland coal region, and it was at length completed to Wheeling on the Ohio. Charleston and Savannah early appreciated the importance of connecting their harbors with the productive districts of the interior by railroads; and when these had penetrated their own states, the line of equal importance to both was extended through N. Georgia into Tennessee, connecting in 1849 Chattanooga with those cities. All these advances into the valleys of the branches of the Mississippi affected the cities of the gulf of Mexico, and Mobile and New Orleans hastened forward the lines which in the early history of American railroads they had projected for securing to themselves the trade of these valleys. From Mobile a road directed toward the mouth of the Ohio has been completed into N. Mississippi; and from New Orleans, through the central part of Mississippi and across W. Tennessee and Kentucky, the Ohio river has been reached at Paducah, a few miles above its mouth. Virginia, seeking the trade of the same region, has also reached E. Tennessee by the roads from Richmond through Lynchburg to Knoxville and Chattanooga, whence the western line already completed to Memphis on the Mississippi crosses the Mississippi railroad at Grand Junction on the southern line of Tennessee, and with this makes the communication complete from Alexandria, Norfolk, and Richmond to New Orleans. The connection between the cities of the Atlantic coast, with the exception of the short break between Washington and Alexandria, is complete by independent roads, planned originally from one city to the next; and from Philadelphia to Portland, Me., by numerous parallel routes. In the N. W. states railroad enterprise has been developed to an extent hardly surpassed in the most populous districts of New England, the construction of roads being there greatly facilitated by donations of land by the government. The longest of these lines is the Illinois central railroad, extending from Cairo at the mouth of the Ohio to Dunleith on the Mississippi river in the extreme N. W. corner of the state, a distance of 455 m., with a branch of 253 m. from Centralia to Chicago. On both sides of this road and its branch the company was endowed with alternate sections of land, of the total width of 6 sections or miles and length of 706 m. Where the lands were already taken up, the company was privileged to select any others within 15 m. of the line of the road. It thus acquired 2,595,000 acres in an excellent farming region, and from the sale of them the expenses of construction, amounting to $23,427,669, are met. In this state, where in 1850 there were only 22 m. of railroad, in 1856 there were 2,750 m. In Wisconsin three ports on Lake Michigan are connected by as many lines of roads with the Mississippi river, the most northern reaching it at La Crosse near lat. 44° N., whence it is to be continued to St. Paul and the falls of St. Anthony. In Iowa several lines are directed W. from the Mississippi, destined to reach the Missouri river, and in N. Missouri the Hannibal and St. Joseph, 206 m. long, and the N. Missouri railroad from St. Louis to St. Joseph, 304 m. long, already make this connection. S. of the Missouri river, what is called the Pacific railroad is completed from St. Louis to Syracuse, Mo., 168 m. In the wonderful progress of railroads throughout the country, the great and unsurpassed natural means of communication between the interior and the seaboard have been found wholly incompetent to meet the increasing demands of the people for the most unobstructed and rapid means of transportation. Railroads are built along the banks of navigable rivers and the great lakes, and from the current of the Mississippi draw away to the distant shores of New England and of the middle states the products that should naturally follow the river to the sea. The most important natural routes of the N. E., where they lie on a direct course, as the two lower lakes and the St. Lawrence river, are bordered on both sides with lines of railroads that extend from the head of Lake Erie to Quebec; and where the inland seas present circuitous routes, as from Lake Ontario to Georgian bay and Lake Huron, and from Lakes Erie and St. Clair to Lake Michigan, these are cut off by various direct railroads across the peninsulas. —The progress of the railroads of the United States in periods of 2 years each, from the year 1838, when the number of miles completed amounted to 1,843, to the close of the year 1860, is represented in the following table, which also designates the lengths of road in each state for the same years:*

States.	1838.	1840.	1842.	1844.	1846.	1848.	1850.	1852.	1854.	1856.	1858.	1860.

---

* It is impossible to obtain correct statements of each year, as most of the roads run into different states, and the distinction is not always made of the number of miles belonging to each state. There is also confusion in the published statistics between the number of miles in actual operation at any time and of those under construction. The last column of figures is taken from the "American Railroad Journal," and was prepared with special care to avoid these sources of error. In the other columns it has been found necessary to change the returned figures occasionally, that the number of miles in operation in any year might not exceed those in operation at the next period of two years. This has been done sometimes by making the figures agree with the succeeding and sometimes with the preceding period of two years. Such changes are too few and unimportant to affect the general value of the table.

The total length of roads projected and constructed in the several divisions of the United States, and cost of the same up to Jan. 1, 1[illegible] are given in the following table:

States.	Total length of line.	Miles in operation.	Cost of roads and equipments.
North-eastern states.			
Maine	689.86	475.86	$16,288,261
New Hampshire	684.29	657.88	22,676,284
Vermont	555.87	555.87	28,240,097
Massachusetts	1,886.68	1,814.85	59,777,878
Rhode Island	186.82	104.82	4,188,888
Connecticut	762.90	607.76	20,948,880
Total	4,165.87	8,785.54	$147,014,288
Middle Atlantic states.			
New York	8,455.87	2,808.96	$145,259,792
New Jersey	844.76	627.28	80,895,081

The comparative statement of the extent and various conditions as to cost and profits of the roads of the principal countries of Europe, of the United States, and of India for the [illegible] named, is presented in the following [illegible] given by English authorities:

Countries.	Years.	Length of line open, miles.	Total capital expended per mile of line open.	Receipts from traffic per mile of line open.	Net receipts per mile of line open.	Proportion per cent. of working expenses to receipts.	[illegible]
Austria	1856	1,586	£16,878	£2,190	£1,040	52.70	[illegible]
Belgium	1856	445	16,891	2,158	898	58.16	[illegible]
France	1854	2,918	25,668	2,706	1,515	44.01	[illegible]
Germany, exclusive of Austria and Prussia	1855	2,226	18,111	1,816	919	49.28	[illegible]
Great Britain—England and Wales	1857	6,706	89,275	8,161	1,597	48.00	[illegible]
Scotland		1,248	28,225	2,107	1,166	44.00	[illegible]
Ireland		1,070	15,664	1,091	626	88.00	[illegible]
Holland	1857	168	19,981	1,709	667	60.96	[illegible]
Prussia	1856	2,508	14,101	1,877	909	51.59	[illegible]
Sardinia	1855	284	....	1,477	708	51.88	....
Spain	1855	180	....	924	409	56.48	....
Switzerland	1856	203	19,888	686	295	54.28	[illegible]
Tuscany	1856	182	15,556	966	520	46.18	[illegible]
United States of America	1855	17,481	8,275	1,284	568	54.00	[illegible]
East Indian	1858–'9	142	12,084	1,447	770	45.04	[illegible]
Great Indian Peninsula	1858–'9	194	8,758	764	427	44.10	[illegible]
Madras	1858–'9	96	7,000	499	234	58.90	[illegible]

The total number of miles of railway open for traffic in Great Britain in 1859, according to the report of the department of railways, was:

In England and Wales	7.217 miles;	receipts,	£9,989.959	17s.	6d.
In Scotland	1,369	"	1.267,792	8	9
In Ireland	1,210	"	604,957	9	8
Total	9,796	"	£11,862,789	10s.	11d.

—Although, before deciding upon the construction of a railroad, the first requisite would seem to be a careful computation of the amount of business already done upon the route in the transportation of passengers and freight, with the view of determining whether this would justify the proposed expenditure, estimates of this character have been found by experience to afford a very uncertain index as to the actual business that would result under the new circumstances. A more enlarged view of the conditions of the country through which the road is to pass is consequently necessary, and a careful consideration of the effects already experienced from the opening of new roads in other similar regions. New branches of trade may be stimulated by the greater economy of transportation offered by the new road, inducing an increase of population and of the travel of passengers, and these as well as freight may moreover be drawn in from other channels of travel. The construction of most of the roads of New England, and to a less striking extent of roads in other parts of the United States, has developed in a wonderful manner what has been called the travelling propensities of the people. This is shown by the following examples, the first column of figures (*a*) representing the estimated number of passengers before the road was built; the second (*b*), the number soon after; and the third (*c*), the number in the year 1848:

Name of road.	*a*	*b*	*c*
Boston and Worcester....	[illegible]	[illegible]	[illegible]
Boston and Lowell......	[illegible]	[illegible]	[illegible]
Fitchburg...............	71,790	[illegible]	[illegible]
Western.................	251,760	[illegible]	1,091,169
Boston and Maine........	....	462,426	[illegible]

A similar increase has been experienced also upon most of the roads in the amount of freight transported. But as railroads have been multiplied and an active competition has grown up among them, such results can now rarely be counted on in short periods. Another consideration, which experience has shown to be a very important one, and which now often induces the construction of railroads, is the influence which these are likely to have upon the value of real estate along their line, and even in the cities where they terminate. Again, as the prosperity of one city is found to advance rapidly from the effect of its railroads, property holders in others, which are injuriously affected by the diversion of trade, are compelled to open similar avenues for their own protection. Thus it has been in the United States that many of the roads have been projected, not with reference to direct remuneration by the business done upon them, but to indirect returns, in which many who ignorantly subscribe to the stock can have no immediate interest.—Preparatory to the location of a railroad, surveys are made along the several routes the road may follow, and plans are constructed representing the exact distances and grades or the amount of deviation from a level at all the points. From these plans are calculated the amount of excavation and embankment, of tunnelling, bridging, &c., necessary to bring the road within the required degree of straightness and level. Thus the estimates are obtained, by comparison of which, including with each also the ascertained amount to be paid for right of way, the location of the road is determined. The importance of the road and the special purpose for which it is designed, as for transportation chiefly in one direction only, or in both, whether it is to be run at moderate or high rates of speed, &c., are to be duly considered in deciding upon saving of distance and reduction of grades by heavier expenditures. Roads upon which numerous trains are to pass daily, each one of which will incur a certain additional expense for every additional mile, and each mile will involve a certain annual expense for keeping in repair, may economically be shortened at increased outlays that would be entirely inadmissible in securing a similar reduction of distance to less travelled routes. So upon roads that are to be run at high rates of speed short curves must be avoided at any expense. It has happened, from the experience gained in the working of railroads, that some of the earlier lines have been economically reconstructed by a partial abandonment of the old routes under more judicious surveys, or from the increase in the business justifying the adoption of a more perfect line. As already remarked, the old system of occasional inclined planes is almost wholly abandoned for roads of general travel, and the construction and capacity of locomotives and carriages is so much better understood, that a much greater range in curvatures and grades is now found practicable than was formerly ever thought of. As regards curves, it was formerly recommended in England to fix the minimum radius that should be allowed at one mile, and in 1846 it was one of the "standing orders" of parliament that no curve could be made less than with a radius of half a mile (2,640 feet) without special permission of parliament. In France a minimum was established by "the administration of roads and bridges" of 2,700 feet, or about 2°. On the Hudson river railroad the minimum curve has a radius of 2,062 feet = 2.75°. But the Baltimore and Ohio road was built with several curves of 400 feet radius (14.25°), and with one of 318 feet (18°), and no difficulty was experienced in running over them at 15 m. an hour. The objectionable features of the curves are avoided by making the wheels conical, of greater diameter within than at their outer edge; the effect of this in running on a curve, when the wheels on the outer side are pushed by the centrifugal force outwardly, is to make them roll on their larger diameter, and at the same time the wheels on the other side, drawn in toward the centre of the track, roll on their smaller diameter. On each side they are thus accommodated to the different lengths they have to traverse, without straining the axles and without greatly increased friction or slipping of the inner wheel upon the rail. The friction against the outer rail due to the centrifugal force is partially prevented by elevating the outer rail. The object of attaching the wheels to their axles instead of letting them turn upon these, is to secure greater steadiness at high speed. The requiring of minimum degrees of curvature has been abandoned upon the English and French roads, and occasional instances are now noted of very short curves, as of 300 feet radius on the Woolwich line near London, and of 529 feet on the great western, great northern, and Newcastle and Carlisle lines. In France, upon the Paris and Orsay and Paris and Sceaux railroads, there are curves of 52 feet radius, and trains, the engines and carriages of which are provided with loose wheels and guide rollers, run through complete semicircles at 20 m. an hour.—Upon the earlier roads in Great Britain and in the United States grades of 30 or 40 feet to the mile were considered heavy, at the last figure nearly tripling the power that was required to draw a load upon a level. Grades of 70 to 80 feet were regarded as almost impracticable, as they would compel the carrying of light loads over the whole line; and therefore, when such grades could not be otherwise avoided, inclined planes worked by stationary engines were adopted. The Hudson and Mohawk railroad, in a length of 16 m., was built with one such plane at Albany, and another at Schenectady. The Philadelphia and Columbia railroad was also built with two planes, one at Columbia and the other near Philadelphia, and there were 10 on the Alleghany portage road over the Alleghany mountains, all of which have been displaced by the substitution of heavier grades on more extended lines. But as experience was acquired in the working of railroads, it was found that locomotives rarely carried maximum loads for the moderate grades, and that a temporary slackening of the speed upon the steep grades rendered a further portion of the power of the locomotive available for overcoming the increased resistance. Thus, when the doubtful point as to the adhesion of the driving wheels to the rails was satisfactorily determined, and the common law of mechanics, that power can be gained at the expense of time, was found to be applicable to ascending grades of a railroad, these were increased much beyond their former limits. High grades were sooner introduced in this country than in Europe, but they have recently been adopted there also. On the Mount Savage and George's creek railroads in Maryland grades of 140 feet to the mile have long been used; and on the Baltimore and Ohio road, through the Alleghany mountains, of 114 feet. In England those of 100 feet to the mile are not uncommon, and there are several from 180 to 150 feet. At Sheffield is a grade of 196 feet to the mile, and the same is seen at Oldham on the Lancashire and Yorkshire road, extending for 1¼ m. In France on the St. Germain railroad is a grade of 123 feet to the mile for about 1¼ m.—In the construction of railroads the proper preparation of the road bed should be an object of the most particular care. Being the foundation and support of the whole superstructure, it should as a matter of economy be made as firm and durable as possible. But it is in this that the American roads are most defective. The least width of embankments for double tracks (and roads of importance should always be laid out for these) ought not to be less than the width of the two tracks, with 6 feet between them, and 6 feet outside of each. In excavations the width of ditches on each side should be added. A common width of embankments in England is 33 feet, while on the principal American roads it is about 27 feet. The transverse slopes of the English roads are much flatter than ours, and are commonly well protected with a good grass sod. But the most essential difference is in the drainage, upon which more than any thing else depends the durability of the earthwork and of the sleepers and rails. Upon some American roads the sleepers are laid directly upon the natural soil, or upon this thrown up in a bank. Where the ground freezes, any superstructure on such a basis is certain to be more or less displaced in the spring thaws; in wet weather it must prove very insecure, and in dry weather very dusty. The sleepers soon settle irregularly, placing the rails out of line, and thus are involved rapid wear, deterioration, accidents, and loss to the rolling stock and to the road. The dust rises in clouds, to the great injury of the machinery and of the passenger cars, and seriously incommoding the passengers themselves. The effects of water about the earthwork of railroads are regarded as so injurious that an eminent English authority says: "Wherever it is known or suspected to exist, its immediate source should be traced, and every possible means adopted for diverting it from the slopes and adjacent surfaces." Not only are capacious and permanent culverts, ditches, and drains abundantly provided, but sub-drainage by tile drains is also employed to great advantage; and as a final precaution the road bed is ballasted, usually a foot deep beneath the sleepers and another foot around and over them, and for a width on double tracks of 26 feet, the quantity per mile amounting to 10,000 or 12,000 cubic feet. The material preferred for ballast is gravel containing a natural mixture of clean sand, and next to this broken stone in pieces not exceeding 2½ inches in diameter. Limestone is not so good as gneiss, as it packs too densely, and trap rock also is likely to become too solid and rigid. A certain elasticity in the bed is essential for the durability of the rails; and where no other suitable material is at hand, common clay burned in lumps in great heaps intermixed with bituminous coal has been found to answer very well, especially if hard-burned. Cinders and small coal are excellent materials, and in Holland shells and broken bricks are extensively used. The French double track roads, from the reports of 1857, expended 115,000 francs per kilometre (equal to $6,039 per mile) for ballast, or 17 per cent. of the whole cost of "way." The road bed through the long English tunnels, and also upon the viaducts, is well ballasted, and the wear of the rails is thereby materially decreased. The wooden sleepers on the European roads are also very commonly protected by some chemical application. (See PRESERVATION OF WOOD.*) The ordinary duration of sleepers upon American roads is hardly 7 years, but upon English roads it is 15 years and upward. By the scrupulous attention directed to these details in building the European roads a great saving is effected in the cost of "maintenance of way," engines, and working. From the report of Messrs. Colburn and Holley ("Per-

---

[*] A method of preserving the sleepers, not mentioned in that article, and practised on the Reading railroad, is as follows. The sleepers, stripped of their bark and notched by machinery to insure a smooth bearing for the rail, are exposed for 48 hours in ovens to as high heat as they will bear without ignition, the smoke and gases from the fire being passed directly among them. They are taken out hot and their ends immediately dipped in hot coal tar. Each sleeper absorbs about ¼ of a gallon of the tar; and the cost for each one is from 5 to 6 cents. Only hard wood sleepers, chiefly oak, are used.

manent Way," New York, 1858) it appears that these items on English lines average less than one half the amount of similar expenses on the railroads of New York and Massachusetts. Only one half as much fuel is consumed to the mile run on the English and French roads as on those of the northern United States; and the consumption of fuel may be taken as a measure of the resistances overcome. If the English trains are from 20 to 30 per cent. lighter than those of American lines, they are run 25 per cent. faster, thus requiring about the same power. The cost per mile of maintenance of way on the London and north-western railway in 1855 is said to have been only one fourth as much as on the New York central. If the proportion had been one half, the saving to the latter road would have been $418,281. Proper original construction as regards earthwork, drainage, and ballast, would without doubt have effected this saving.—The superstructure of railroads is almost universally upon transverse wooden sleepers, the primary object of which is to give a steady bearing upon the road bed. Seasoned white oak is preferable to any other wood for strength and for holding the spikes. Hemlock is better than chestnut, and both these are extensively used in the United States. Their dimensions are commonly 8 feet long and 7, 8, or 9 inches width of bearing surface, and their distance apart from centre to centre is from 2 feet 1½ inches, as on the Erie road, to 2 feet 6 inches. Upon the English roads they are commonly 9 feet long, 10 inches wide, often squared, and 5 inches thick. They are usually laid 3 feet apart from centre to centre; and that a uniform bearing may be secured, particular care is taken that the sleepers are alike in size and regularly spaced in their beds. In France the experiment has been tried of cutting the sleepers in two in the middle, leaving one in every 10 or 12 feet to bind the two rails together. The result was very satisfactory, the object being to prevent the spring of the full-length sleepers or the movement they sometimes acquire on their centre. But for these and detached rectangular blocks of any material either transverse or longitudinal, it is essential that the supports should be well packed upon a thoroughly ballasted road bed. In England, where wood is expensive and iron comparatively cheap, rectangular blocks of cast iron have been tried upon some of the roads, and with good results; but the conditions of cost are altogether unfavorable to their adoption in the United States. Granite sleepers have been tried and have continued in use upon one of the tracks of the Boston and Lowell road. They make a very hard and rigid support, and cannot be used in connection with wooden sleepers interspersed or alternating with them, unevenness in the track soon resulting. The smooth face of a rock ledge has been tried upon the Manchester and Leeds road, the rails being spiked directly down upon it. It was soon found necessary to take them up on account of the excessive wear upon the rails thus placed. The great western road in England is constructed with longitudinal bearings or sills measuring 10 inches square, and framed together by cross ties of 6 by 4 inches every 6 feet. The arrangement is said to be easy on the rolling stock, but as regards cost of maintenance of way this is one of the most expensive roads in England.—The rails, which are straight bars of wrought iron, differ greatly in the shape of their cross section, their weight, quality, and the manner in which they are secured to the road bed. Almost the first form was the fish-bellied rail, made about the year 1820. This soon gave place to others of more economical shape, as the T and the I rails, and to these was added the bridge or hollow rail, the form of which is nearly that of the letter U inverted. These have been variously modified in their figures and proportions, and a great number of other forms that may not be referred to either of these have been introduced upon different roads. In the United States an inverted T rail has been in very general use, so as to be known as the American rail. It has a broad bearing foot, and is easily secured to the sleepers by hook-headed spikes driven into elongated slots in the edge of the flange, or merely over the edge, thus allowing expansion and contraction of the rail with changing temperatures without disturbing the fastenings. With this rail cast iron chairs, employed for seating and holding almost all other rails, are not required except at the joints, and the additional cost of the iron, which is an important consideration on American roads, is saved. A favorite rail in England is the I or double-headed rail, which has the advantage of furnishing two sides for wear, being easily taken out of its chairs and turned over when one side is worn out. Professor Barlow's modification of this is also much used, the foot of which is much smaller than the head. The saddle-back rail of the same inventor has a split foot its whole length, the parts spreading like a saddle. It was designed to be imbedded in the ballast without sleepers, and with occasional ties of iron rods, connecting the two rails. About 900 m. of track were laid with this rail in 1858, but it did not prove altogether satisfactory, and cross sleepers were found to be essential for its stability. It is remarkable that in the long lengths of 5 or 6 m. in which the rails were firmly riveted together no accumulated motion by expansion and contraction has been observed. Compound rails, patented in England in 1847, have not been adopted there. A form is in use in this country, in which the portion of the rail beneath the head appears as if split its whole length into two parts, and these being placed so as to break joints are riveted or bolted together through their sides. Up to about the year 1854 the weight of rails had been steadily increasing from about 35 lbs. to the lineal yard, till it had reached in England 80 to 100 lbs.

No advantage was found in the very heavy rails, however, but on the contrary the iron in such large piles was necessarily less worked in the manufacture and was in a poor condition for wear. The tendency has since been to return to lighter rails, of 55 to 65 lbs. to the yard, and to require these to be made of iron originally good, the piles to be first rolled into blooms, and these to be again brought to a welding heat, and then rolled into rails. The miserable quality of much of the iron on American roads is due to deficient working, the fibres of the iron as it wears showing that they have never been thoroughly incorporated together. In bargaining for it no test and no particular conditions of manufacture were required, as is customary in other countries. Rails of 45 lbs. have worn under the heaviest traffic for 20 years, as those laid in 1837 on the Reading railroad, while others of nearly double the weight have given out on other roads in 1, 2, or 3 years. The first rails employed on the Stonington railroad, of 54 lbs. to the yard, also lasted 20 years. Rails have been made in lengths of 15, 16, 18, and 20 feet, and recently of 21; on one road in England 30 feet rails have been used. An important feature in the rail is its height or depth. Its stiffness, if the rail could be regarded as a rectangular beam, increases as the square of the depth; thus doubling the height and retaining the same weight of material quadruples the stiffness, but doubling the height and weight also increases its stiffness 8 times. The effect of a want of stiffness in the rail is deflection between the supports under the weight and a mashing of the iron into the wood of the sleepers, which continually increases the mischief. Even between rigid supports the temporary depression of the rail is such as to present a continual ascending plane in front of the wheels, which the descent of the slope from behind does not in any measure compensate, the advantage of this being wholly balanced by other considerations. But high rails require strong lateral supports. These on the English roads are furnished in the cast iron chairs on every sleeper, and by the stiffening of the rails at the ends by the peculiar joint in use; and the English are thus able to employ much deeper rails than are seen upon our roads. Unless of the ∩ form (and this is now little used), their rails are rarely so low as 4½ inches. They run from this to 5½ inches, and present a head of about 2½ inches, the surface of which is convex, the curve having a radius of about the height of the rail. The American rails differ from these chiefly in the height, which is rarely so much as 4 inches, but commonly about 3½. On the Camden and Amboy road was laid a rail of 92 lbs. to the yard, with a broad foot to secure lateral support, and of the extreme height, first introduced in England, of 7 inches; but the use of such a rail has not been adopted on other roads. High rails do not necessarily involve a great weight compared with that of many low rails now in use; for the latter often contain a useless amount of iron, especially in the bulge beneath the "pear-shaped" head, and also in the thickness of the web, which need not exceed ¾ of an inch. The excess of metal which does not add to the strength, and the presence of which actually interferes with the proper working of the iron to make rails of good wear, may amount to 12 tons or more to the mile; a saving well worthy of consideration, especially where iron commands a high price.—The securing of rails to the track and keeping their ends together are provided for by a variety of expedients. In all of them it is necessary to recognize the principle of contraction and expansion of the rails by changes of temperature, and in the laying of the rails proper allowance is always made for this; thus rails 20 feet long, at the temperature of 100° F., may be set close together at the ends. If laid at 80°, a space should be left of .032 in.; at 60°, .065; at 40°, .098; at 20°, .131; at 10°, .147; at 0°, .168; and so on. By neglect of this precaution it has happened that the rails heated by the sun have expanded so as to thrust upward, lifting the sleepers out of the ground to the height of one or two feet. From this cause, a train running in June, 1856, on the north-eastern railway in England, at [illegible] m. an hour, was thrown off the inside of a curve, though the 82 lb. rail was fastened every 3 feet in heavy chairs and "fished" at the joints. Almost the universal fastenings in England used to be cast iron chairs, made to hold the rail in an opening in the top, into which it was seated and keyed by a wooden wedge. The chairs were themselves strongly bolted down upon the sleepers. Those for receiving the two ends of adjoining rails are much heavier and stronger than the others, weighing from 26 to 39 lbs., the others 18 to 26 lbs. It is of great consequence to keep the ends of the rails securely upon the same horizontal line. If one end is depressed by the weight coming upon it, the wheel strikes the end of the next rail with a concussion that soon shatters the rail, and being repeated at other joints seriously injures the rolling stock. Various methods of keying the ends in the chair are in use, one of the strongest of which is that known as Burleigh's, with a tapering iron key 14 inches long. What are called [illegible] joints were designed in 1847 to keep the ends in line. As first proposed, two sleepers were to be placed 6 inches apart at the joints, and two plates of iron slightly wedging were to be driven one on each side between the jaws of the chairs flat against the sides of the two rails. Instead of this, however, a pair of plates 18 inches long, ¾ of an inch thick, and about 3 inches wide, are bolted together through the rails with ¾ or ⅞ inch bolts, the holes in the rail being elongated to allow for contraction and expansion. The same plan was tried in 1843 at New Castle, Del.; but it was found incompatible with low rails such as are used in this country. Though extensively used in Europe, the arrangement is open to serious objections; and the angle bracket was patented in 1853 as a substitute. This consists of two braces either of cast or wrought iron, each made with a flat foot, which is spiked to the sleeper upon which the joint comes, one on each side of the rail, and their upper edges fitting under its head are bolted together through the web of the rail. The wedge method in chairs is preferred on American roads, though the angle bracket is well adapted for the rails in use. Upon the Camden and Amboy road a singular connection called a ring joint is made to hold the ends of the rails. The face of the rails for two inches at each end is cut down so as to receive a strap, which is shrunk over them; the width of the strap is about 4 inches, and its thickness is just equal to the depth of the portion cut out. Rails are sometimes relieved from violent jarring by means of a cushion or spring of India rubber placed either under the rail or under the chair which holds it. A method of suspending the rails by a continuous bearing applied on each side under the head and bolted through the rail has been introduced in England within a few years past by Mr. W. Bridges Adams, and is regarded by many as likely to supersede all the other methods of supporting the rails. It is known as the suspended girder rail, and is used either with angle iron brackets or with timber bearers, one laid along each side the rail and bolted through. The angle brackets have the form of long flat strips of iron turned up longitudinally at right angles. They are placed with the angle under the head of the rail, the narrower part of 2 or 3 inches width fitting in the space between the head and foot of the rail, and the wider strip extending out horizontally from the under side of the head to a distance of 4 to 6 inches. Bolts pass through every 2 or 3 feet. No two joints are allowed to come opposite each other, and the three pieces are thus firmly secured together. The two rails are held to their gauge by occasional tie bars, which are fastened at their ends by some of the bolts which secure the brackets to the rails. The rail is of the common double-headed form, 7 inches deep, and is laid directly in the ballast. It derives its main support from the horizontal wings or brackets, and also bears upon its under surface. This arrangement secures great stiffness both vertically and laterally, and the load being taken directly under the head of the rail the web between the top and bottom may be of much thinner iron than is ordinarily used. In using timber bearers instead of continuous angle iron brackets, considerable saving is effected in the first cost, and an equally stable support is obtained. The timbers are scantling of equal depth to the side channel between the head and foot of the rail and about 5 inches width, thus making with the rail a bearing width of 10½ inches. Instead of bolts, flat bars of iron are used to secure them, passing through vertical slots, and held at the ends by keys. At the joints of the rail angle brackets are used 18 inches long bolted down to a cross sleeper.—In order that trains of cars may pass from one track to another an extra pair of rails are laid down, which can be moved so as to complete the connection with either one of the lines as desired and break it with the other. These movable rails are called switches, and are controlled by a long bar under the surface connecting with an upright lever at the side of the road. This is in the care of the men known as switch tenders, whose duty it is to see before the approach of every train that the rails are so placed as to carry it upon the right track. Turn tables are circular platforms which can be pushed round upon a circular track sunk below the level of the ground. A locomotive or car being run on to the platform, it is thus easily turned about or directed upon any other diverging track, numbers of which usually concentrate around the turn tables.—In treating upon railroads numerous important considerations present themselves beside those already noticed, each of which should receive particular attention. Such especially are the viaducts, bridges, and tunnels, and the immense cuts or excavations and embankments; also the processes employed by the engineers in laying out the road, their seeking for the most level and the straightest line while restricted by the amount of means provided, and planning the excavations and embankments, so that the material supplied by the former shall amount as near as may be to that required by the latter. The station houses, which in themselves are an important class of structures peculiar to this new improvement, merit a particular description; as also the varieties of carriages in use upon the road, the locomotives, &c. The last named will be noticed in the article STEAM CARRIAGE. Mention is made of some of the principal railroad bridges in the general article BRIDGE. A passing notice only may be given to the tunnels, always a remarkable feature of engineering, but especially so in the large scale upon which they have been constructed for railroads. In Great Britain they amount to about 70 m. in length, which is equal to about $\frac{1}{115}$ of the whole length of all the roads; and the total cost is estimated to average £102 for every mile of railroad. In the United States, in a total length of over 31,000 m., there are only about 13 m. of tunnel. In Great Britain it is considered cheaper to tunnel through rock than to make open cuts deeper than 60 feet. Where the rock is insecure at the sides and top the tunnel is lined with brick in several successive rings, and the upright arch is sometimes supported upon an inverted arch built under the rails. The longest tunnel is the Woodhead, at the summit of the Manchester, Sheffield, and Lincolnshire railway, its length being 3 m. 60 ft. The Standedge on the London and north-western railway is 3 m. long; and 12 others on other roads exceed 1 m. each. The Box tunnel on the great western railway, between Bath and Chippenham, is 3,123 yards long, or rather more than 1¾ m. It is 30 ft. wide, 25 ft. high, and 70 ft. below the surface. It is ventilated by 11 air shafts, most of which are about 25 ft. diameter. The Kilsby tunnel on the London and north-western railway is 1 m. 1,914 ft. long, 30 ft. wide, and 30 ft. high, 160 ft. below the surface, and is aired and partially lighted by 2 shafts of 60 ft. diameter. The total cost was £320,000, though contracted for at £99,000. The increased expense over the estimates was caused by quicksands. The Shakespeare tunnel through the chalk cliffs near Dover, on the south eastern railway, is composed of 2 narrow tunnels each 12 ft. wide and 30 ft. high, separated by a solid pier of chalk 10 ft. thick. It is 1,430 yards long, and is provided with 7 vertical shafts from the surface averaging 180 ft. deep. The tunnel laid out under the Alps between Modane in Savoy and Bardonecchia in Piedmont, to connect Italy with France, will when completed be about 8 m. in length, and at such a depth beneath the surface as to render shafts impracticable. It can therefore be worked from each end only, and serious difficulties must be encountered in ventilating as well as expediting the operation, which at the usual rate of excavation would occupy at least 40 years. A new method of ventilating and driving has been applied to this work, and by the machines now in use, according to reports received in July, 1861, the tunnel is extended on the Italian side rather more than 8 feet per day to a width of about 10 feet. Most of the tunnels upon American roads are on the lines crossing the Alleghany mountains. Through the main Alleghany ridge, near its summit, a tunnel was completed in Jan. 1854, for the Pennsylvania railroad, the length of which is 3,612 ft., width 24 ft., height 22 ft. To expedite the work and facilitate the removal of the rocky materials, three shafts, each measuring 6 by 10 ft. and of the respective depths of 150, 196, and 154 ft., were sunk from the surface down to its level; and a fourth of larger dimensions, 8 by 13 ft., was afterward found necessary; this was 194 ft. deep. The rocks are the nearly horizontal strata of the coal measures, the tunnel in great part lying along a bed of fire clay, which, though easily excavated, caused considerable expense in properly securing the walls and roof. The work was done in 2 years at a cost of $450,000. A great number of short tunnels are found on the line of the Baltimore and Ohio road, particularly on its extension, the north-western road of Virginia. The Blue ridge railroad crosses the Blue ridge in Virginia by a tunnel 4,273 ft. long on a grade ascending west of 70 ft. to the mile. Its height is 21 ft., greatest width 16 ft. The work was carried on from each end at the rate of nearly a foot every 24 hours. It was commenced in 1850 and finished in 1857, without shafts, at a cost of about $464,000. On the Blue ridge railroad in South Carolina three tunnels are nearly or quite completed in Pickens district, of which the shortest is 616 ft. long, and the longest, the Stump House mountain tunnel, is 5,864 ft. Four shafts are sunk from the summit to expedite the work. In the N. E. corner of Georgia, on the same road, are two tunnels. The long dock tunnel in Bergen, N. J., opposite New York city, was completed in 1860. It passes through the trap hills that extend from the Palisades S., and is 4,31[illegible] ft. long, 23 ft. high, and 30 ft. wide. Eight large shafts 70 to 90 ft. deep were sunk from the summit down to its level. The longest tunnel projected in the United States is that through the Hoosic mountain in Massachusetts, between the heads of the Housatonic and Deerfield rivers. The total length is 24,500 ft., or 740 ft. over 4⅔ m.; the height is 18 ft. and width 14 ft. The mountain is of mica slate and quartz rock, and rises 1,700 ft. above the level of the tunnel, so that shafts have been considered entirely out of the question. One, however, was started in 1861. In May, 1860, the work had been pushed in 1,683 ft. on the E. side and 800 ft. on the W. With such means as are at command for ventilating, it would seem to be almost a hopeless undertaking to endeavor to penetrate this mountain. Should the task ever be accomplished, the distance from Troy to Boston will be reduced from 208 to [illegible] m., with an important reduction also of the grades and curves.—The comparative economy in the construction and working of railroads in different countries is a subject of the first importance, and one to which many competent engineers have given particular attention. While the English roads exhibit an extraordinary amount of first cost, it does not appear that the expenditures for actual construction have been in much larger proportion than in the United States, but it is the extremely heavy out-[illegible] expenses that absorb the capital. Still, though the same amount to the mile should be expended for the construction of the road in both countries, a great difference would be observed in the result from the greater cheapness of labor and materials in England. This is shown by the following estimates, one for each country. The former is for a thoroughly first class road with ample slopes and ditches, deep ballast, a 70 lb. rail, fish-jointed, and the sleepers chemically preserved to last 15 years. The second, or American line, has scanty earthwork, thin ballast, a 60 lb. rail, with open joints, and the sleepers destined to decay in from 5 to 7 years.

Total		$14,526 00

Among the great items of cost upon English roads, the first in amount is compensation for land, the most extravagant prices being awarded and largely increased by numerous heavy charges. The average upon all the lines has been rated at $45,000 per mile, or more than the entire average cost of American roads. The "parliamentary expenses" incurred in obtaining a charter are also enormous. Upon 6 lines these have amounted to an average of $7,254 per mile, while on several others this amount has been very far exceeded; the great northern, for example, having paid about $5,000,000, which for 314 m. of road is about $16,000 per mile. The several items included in financial management, as interest, discount on loans, bonuses, &c., are estimated at full $20,000 per mile. Larger expenditures than are usual in the United States are involved from the more unfavorable physical features of the country, the topography presenting no long lines of water courses, nor wide table lands, both which are common in this country. Boggy districts are also more frequent in England, and the construction of a permanent road across these has often cost immense sums. Even when the embankments through them have been apparently completed, as much more material has in some cases been required for their maintenance in consequence of their subsidence. The bridges, viaducts, tunnels, &c., are much more numerous and expensive structures upon English than American roads. The superior equipment of engines and carriages adds a considerable amount to cost per mile, some of the roads having even more than a locomotive for every mile, the cost of which averages about $12,000 each. Among the heavier items of expense are the approaches to the cities, London particularly. The roads for several miles are frequently constructed upon arched viaducts of brick. The London and Greenwich line, 3¾ m. long, thus built, cost $1,299,651 per mile; the London and Blackwall, of the same character, cost $1,406,004 per mile. From such causes the total cost of English roads has amounted to about $179,000 per mile. The French double track roads in 1857 were estimated to have cost $101,877 per mile; about ⅓ of the whole was for earthwork and "works of art," as bridges, viaducts, and tunnels; ⅓ for rails, chairs, ties, and keys; and $6,039 for ballast, much more even than upon the English roads. Few roads in the United States have reached an expenditure for construction equal to that of the least expensive roads of Great Britain; and the average cost of all those of the United States is estimated at less than $40,000 per mile. The effect of the more finished condition of English roads is shown in a remarkable degree in the comparative cost of maintenance of way, or of keeping the roads in working order, and of the running expenses, as exhibited in the following table, prepared from the results of the working for 1855:

Names of roads.	No. of miles of single track.	Average number of trains daily each way.	Average cost of repairs per mile of single track.	Average cost of repairs per mile run, in cents.
London and North-Western	1,290	21.7	$402.36	8.24
Eastern Counties	1,152	13.8	450.22	4.90
London and Brighton	654	19.50	544.05	8.13
Great Northern	620	20.97	780.14	8.82
New York Central	862	12.40	613.03	54.96
New York and Erie	741	18.20	657.57	14.64
Harlem	136	9.63	704.29	56.16
Average of New York roads	2,542	10.80	656.97	28.26

In 1857 the average expenditures for maintenance of way per mile run on the English roads were estimated at 10.50 cts., in France at 7.8 cts., and in the United States at 25 cts. In the consumption of fuel a difference quite as striking is observed. In Great Britain the distance run to the ton of bituminous coal or of coke varies from 75 to 118 m., the latter having been attained for a full year on the Cork and Bandon line in Ireland, the fuel being coke. A fair average is considered to be 77 m. On the Baltimore and Ohio road in 1857, for every ton of bituminous coal consumed the number of miles run was 33¼; and on the Reading road, for every ton of anthracite, 19.1 m. Allowing 1½ cords of wood as an equivalent to a ton of coal or coke, the comparative running of the trains on the roads of the northern states is about 25 m. As regards loads, the English trains, though drawn by heavier engines, are lighter than the average of American trains; but this is offset as to cost and wear by the greater speed at which they run. The estimated number of passengers to the train in 1855 was 46, upon the Massachusetts roads 53, and upon those of New York 72.6. On the New York roads the number of tons to each freight train was 71.2. The rate at which trains are run upon the English roads is not so high as it was formerly. Passenger trains run from 18 to 40 m. an hour, the latter being the speed of some of the express trains; the average rate is about 27 m. Freight trains average about 15 m., including all stops. The highest rate attained for a few miles together has been 93 m. per hour. A speed of 60 m. is made daily for short distances, and sometimes even of 75 m. an hour. The average speed is considerably greater than on the French roads, and full 25 per cent. greater than on the American. In 1854, when the trains were run at the highest speed in Massachusetts, passenger trains averaged for the year about 24 m. an hour, and freight trains 12⅝ m. The same was the average rate of passenger trains in New York in 1855; express trains running 33 m. an hour and accommodation trains 22 m., and the average being 24 m. In 1861 the rates of the express trains between New York and Boston are 29½ m. an hour, distance 236 m.; on the New York central road 26 m. an hour, distance 290 m.; on the Hudson river road 24 m. an hour, distance 144 m.; on the Erie road 22 m., distance 459 m. The last is the rate between New York and Philadelphia; and between Philadelphia and Baltimore it is 24 m.—*City Railroads.* Although railroads were long used in Great Britain with horse power only, this method of working them has been there generally abandoned; but in the United States their peculiar adaptation for the streets of cities was early perceived, and they are now in use upon the principal thoroughfares of most of the cities. Cars carrying from 25 to 40 passengers are easily drawn by two horses at the rate of 5 or 6 m. an hour, and take the place of a much larger number of omnibuses, running at the same time at considerably less expense. The trucks turning upon pivots, the carriages turn round the corners of the streets without difficulty; and the rails being laid nearly flush with the surface, no obstruction is presented by them to the passage of vehicles across the track. The importance of this application of railroads being fully established by long trials, an American (Mr. G. F. Train) undertook in 1859 to introduce them into England, and in 1861 the first roads of this character were in successful operation in the streets of Liverpool and London.

RAILWAY, ATMOSPHERIC. See ATMOSPHERIC RAILWAY.

RAIMBACH, ABRAHAM, an English engraver of Swiss extraction, born in London in 1776, died in 1843. His plates after Smirke for Foster's illustrated edition of the "Arabian Nights" first brought him into notice, and subsequent to 1812 he enjoyed a considerable reputation for his line engravings from the chief pictures of Wilkie. Among these were the "Rent Day," the "Village Politicians," the "Cut Finger," "Distraining for Rent," &c. His autobiography was printed for private circulation by his son, under the title of "Memoirs and Recollections of the late Abraham Raimbach, including a Memoir of Sir D. Wilkie, R.A."

RAIMONDI, MARC' ANTONIO, an Italian engraver, born in Bologna in 1487 or 1488, died subsequent to 1539. He was instructed in design and *niello* work by the Bolognese painter Francesco Francia, some of whose pictures he engraved as early as in his 15th year. Subsequently he imitated Mantegna and Albert Dürer, and while on a visit to Venice made facsimile copies on copper of the latter's set of 36 woodcuts representing the life and passion of the Saviour, to which, according to Vasari, he attached Dürer's monogram. The plates however are without the mark of that master; but another set of 17, representing the life of the Virgin, have his mark, and the imitation was so exact that Raimondi's prints readily sold for originals. Dürer was obliged to visit Venice to procure redress, and succeeded in preventing the further surreptitious use of his monogram. The career of Raimondi properly commences in Rome, whither he next proceeded, and where he was employed during the lifetime of Raphael in engraving the choice works of that master. Among the first of these were the "Death of Lucretia" and the "Judgment of Paris;" and as Raimondi gained in boldness and facility of execution, the professional relations of the two artists became very intimate. After the death of Raphael he was employed for some time in engraving the works of Giulio Romano, and he is also said to have excited the wrath of Pope Clement VII. by executing a set of obscene prints, for which he was thrown into prison. Having appeased the pontiff by an admirably executed plate after Bandinelli's picture of the "Martyrdom of St. Lawrence," he pursued his art in Rome with undiminished success until the sack of the city by the constable de Bourbon in 1527, by which he was reduced to poverty. He returned to Bologna, where he resided until his death, actively employed in engraving. For purity of outline, correct expression, and drawing, he was one of the most remarkable engravers on record. The British museum has 500 of his choicest productions.

RAIN, the moisture of the atmosphere condensed and falling in drops to the earth. Some of the principles connected with the formation of rain have been treated in the articles CLOUD, DEW, and FOG. (See also ANDES, ATMOSPHERE, HAIL, METEOR, and METEOROLOGY.) Little was known of the agencies by which the waters of the earth are raised up and form clouds which float in the atmosphere, and at last precipitate their waters back to the earth, until the enunciation of the theory of rain by Dr. James Hutton in 1787. The principle thus announced was mainly that when air is suddenly chilled its capacity of holding moisture in the state of invisible vapor is diminished, and the excess of moisture present becomes visible and is set free in particles which coalesce and form rain drops. Sir John Leslie illustrated and applied this principle as follows: "Suppose equal bulks of air in a state of saturation, and at the different temperatures of 15° and 45°, were intermixed, the compound arising from such union will evidently have the mean temperature of 30°. But since at these temperatures the one portion held 200 parts of humidity and the other 800, the aggregate must contain 1,000 parts, or either half of it, 500; at the mean or resulting temperature, however, this portion could only suspend 400 parts of humidity, and consequently the difference, or 100 parts, amounting to the 200th part of the whole weight of air, must be precipitated from the compound mass." For air not entirely saturated with moisture the amount set free would obviously be proportionally less. On account of the greater proportional capacity of air at high temperatures for holding water, it is also obvious that the higher the temperature at which the change takes place the greater is likely to be the fall of rain, and such is observed to be the case in the heavier showers of summer and of tropical climates. The cause of the chilling is supposed to be the meeting and intermixing of currents of air of different temperatures; and the amount of rain produced by this intermixture will depend upon the degree of saturation with moisture of the currents, the elevation of their mean temperature, and the difference of their respective temperatures. It has been supposed that this explanation did not sufficiently account for the magnitude of the phenomena as often exhibited, sometimes even unaccompanied with any appearance of commingling currents; and electrical action has been suggested as a possible means of retaining the particles of moisture in the air by repulsion among themselves, and that when freed from this influence they coalesced and fell as rain. While it is very possible that there may be some other agency by which the air is chilled beside that of an approaching current of colder air, the electrical hypothesis cannot be admitted until sustained by positive proofs.—The distribution of rain over the earth is governed by the winds and the local conditions of the surface. The chief source of the supply being the great oceans, and the winds sweeping over these and becoming charged with moisture, the precipitation must take place wherever it is gathered in quantities beyond the capacity of the air at its existing temperature to retain it; and thus it is along the equatorial belt that the rainy regions of the earth are in great measure found. For toward this belt in the northern hemisphere the trade winds almost universally blow from the N. E., and in the southern hemisphere from the S. E. As they meet under the equator the airs, intensely heated by the sun and charged to their fullest capacity with moisture, are turned upward, and ascend into the cool regions of the higher atmosphere. Here, being chilled, vast bodies of water are set free and fall back to the earth in torrents of rain. The frequent changes of temperature involved by these movements occasion violent squalls, tornadoes, and thunder storms, without the occurrence of which scarcely a day passes. The rains however are not constant, and in some portions of the rainy zone their fall is very generally limited to a few hours in the afternoon, the morning and evening being bright and clear and the nights cloudless. But in the East Indies, the Chinese seas, and about Sumatra and Java, the tropical rains are sometimes most frequent at night. The belt in which this operation goes on, and which encircles the whole earth, as the rings of Saturn encircle that planet, moves N. and S. with the progress of the sun in the ecliptic, forming a thick and protecting curtain against its rays for all those places over which its path is in the zenith. Thus the tropical rains move with the seasons, passing in our springtime N. from the equator to their N. limit at the summer solstice, when the belt swings back again with the sun, carrying over the regions which it twice crosses entirely a second rainy season, and at the winter solstice it reaches its southern terminus. The quantity of rain that falls is so great, that in the 78 or 80 days in which the belt is passing over the equator the total amount is estimated at 95 inches, or an average of 1.14 inches daily. A better idea is had of this vast amount by comparing it with the fall in the rainy days of other places, as in St. Petersburg, where the yearly rains, occurring in 169 days, reach only to 17 inches, or to a daily average of about $\frac{1}{10}$ inch. The width of the rainy belt is greater than that of the equatorial calms, as the rains encroach to some extent upon the bordering belts of the trade winds, as would occur by the lifting up of the sur-saturated airs into the elevated regions above the calm belt, and there overspreading to the N. and S. The exact limits of the belts cannot be defined even on the ocean; but the calm belt has been observed in July and August between lat. 7° and 12° N., or occasionally further in that direction, while in March and April it is between lat. 5° S. and 2° N. The whole sweep of the rainy belt from N. to S. is usually estimated at more than 1,000 miles. Upon the land the position of the belt is still more uncertain, the influence of the topographical features of the country very materially modifying the extent of the phenomena. Ranges of mountains covered with snow cause a sudden precipitation of all the moisture in the clouds, while extensive regions under the lee of the mountains receive no rain for years. The arid deserts too, by the strong heat reflected from their surface, disperse the rain clouds; and though, like the southern border of the great desert of Sahara, they may lie in close proximity to the rainy belt, little or no water may fall upon them. The great rainless districts of the globe comprise: 1, the whole N. portion of Africa (except a narrow margin on the Atlantic and the contiguous regions along the Mediterranean), thence extending through Arabia, a part of Persia or Iran, and a part of Beloochistan, to the N. borders of Hindostan, a territory altogether of about 3,000,000 sq. m.; 2, the desert of Gobi and the table land of Thibet and Mongolia, which carry the same desert range on to the N. E. into the borders of China and Tartary, and include 2,000,000 sq. m. more; 3, on the American continent, the desert region under the W. slope of the Andes along the Pacific in Chili, Bolivia, and Peru; 4, the small district of Cumana, the N. extremity of South America; 5, the W. coast of Mexico and a belt of country thence extending N. into Arizona. In other regions are numerous districts subject to droughts from their peculiar positions, such as being separated from the great sources of supply of rain by intervening mountain ranges, which also lie in the direction whence come the prevailing winds. All the rainless regions are not necessarily deserts, the moisture held in the atmosphere and deposited as dew being sufficient to sustain vegetation. This is the case at Cumana, and various places on the W. coast of America; and also in upper Egypt and other portions of the dry regions of the East. Fertilizing streams moreover may have their sources, like the Nile, in the districts of the tropical rains.—Nowhere is the effect of the winds upon the distribution of rain more marked than in the Indian ocean in the region of the monsoons. During the prevalence of the S. W. monsoons from April to October, the ordinary routine of the tropical rains is disturbed, and the parched deserts to the N. drawing the air in that direction, torrents of water are poured down upon the W. coast and the mountains of Hindostan; but the N. E. monsoons succeed and blow from October to April, bringing down upon the eastern coasts the waters raised up from the bay of Bengal. In temperate regions the distribution of rain, like the winds upon which it depends and the geographical features which affect its precipitation, is much more irregular, and, though in some localities fluctuating more or less with the seasons, cannot be referred, like the rains of the tropics, to well defined periods. In general the rain falls at all seasons, and the zones outside of the tropics are consequently known as those of "continuous" rains, in contradistinction to the inner zone of "periodical" rains; but in those localities where it is most frequent, it often happens that the quantity precipitated during the year is less than in other places where showers are more rare, but heavier. This is particularly the case when the comparison is made between the rains of the tropics and of the temperate latitudes. A diminution in the quantity is experienced in passing from the tropics toward the polar regions; and, as roughly estimated by Humboldt, the average depth which falls in the latitudes 0°, 19°, 45°, and 60° may be taken respectively at 98, 80, 29, and 17 inches. So from the coasts into the interior of countries, at least in the eastern hemisphere, a like falling off is observed in the supply of rain; and so far as observations have been made similar results are found to obtain in North America, though from the configuration of the sea and land the interior of this continent is open to supplies brought by the winds from the S. as well as from the Atlantic ocean. The mean annual quantity of rain and the number of rainy days are thus given, as observed in different parts of the world:

EASTERN HEMISPHERE.

Between lat. 45° and 50° N.	Depth of rain, inches.	No. of rainy days.
British islands	32	156
Western France	25	152
Eastern France	22	147
Central and N. Germany	20	150
Hungary	17	111
Eastern Russia, Kasan	14	90
Siberia, Yakootsk	?	60

WESTERN HEMISPHERE.

Between lat. 41° and 43° N.	Depth of rain, inches.
Cambridge, Mass.	[illegible]
Western Reserve College, Ohio	[illegible]
Fort Crawford, Wisconsin	[illegible]
Between lat. 38° and 40° N.	
Philadelphia, Penn., and Lambertville, N. J.	[illegible]
Marietta, Ohio	[illegible]
St. Louis, Mo.	[illegible]

That the quantity of rain which falls upon par-ticular localities, though dependent upon the general laws of the distribution of rain, is ma-terially affected by local features of topogra-and temperature, is shown by records of annual fall. In the tropics of the eastern he-sphere this is estimated at 77 inches of w-and in the western hemisphere at 115 in-but at Paramaribo, Dutch Guiana, in la-49′ N., it amounts to 229 inches; at Maran-Brazil, in lat. 2° 32′ S., 276 inches have b-observed; and at Mahableshwur on the Ghauts, in lat. 18° N., 302 inches, which is the largest quantity ever noticed. At Singa-the annual mean is 190 inches; at Mar-Guadeloupe, lat. 16° N., 286 inches. At o-places in latitudes crossed by the rainy b-striking contrast to these figures is obser-At Santa Fé de Bogota, lat. 4° 36′, the fa-89 inches; this is at an elevation of 8,684 f-and mean temperature of 58° F.; at Marma-lat. 5° 27′, 64 inches, elevation 4,674 feet, m-temperature 68° F. At localities within the tropics but outside of the rainy belt, wh-periodical rains following the sun prevail-least upon the land, but with less violence th-in the equatorial belt, the differences obser-are less marked. At Vera Cruz, lat. 19° 11 N. the annual fall was found to be 64 inches; a-Havana, lat. 23° 9′ N., 91 inches; at Calcutta lat. 22° 35′, 76 to 118 inches. In the tempera-regions the mean annual amount of rain in the eastern hemisphere is 34 inches, and in the western 39; considerable differences, however exist in different places. At Brussels and Paris the fall is 19 inches; at Florence, 4-Lyons, 39.5; Marseilles, 18.4; Rome, 31 to 38; the Great St. Bernard, 60; London, 2-to 25; Glasgow, 21.33; Edinburgh, 25; Liverpool, 33.3; Manchester, 36.14; S. W. coast of Portugal, at Lisbon, 27; Madrid, not more than 10. In contrast with this minimum amount Coimbra, at the W. foot of the Sierra d'Estrella, in the valley of the Mondego in Portugal receives more rain than any other place in Europe, the quantity observed having been variously estimated at 118, 123, 135, and 2-inches.—In other latitudes beside the tropics the fall of rain is not uniformly greater in the summer than in the winter months, but sometimes the opposite. In London, from January to July inclusive the results of 40 years' observations give a fall of 8.529 inches, and from July to December inclusive 12.147 inches. The following is a statement by Prof. Daniell of the amount that fell each month of the year:

Jan.	1.483	April	1.786	July	2.516	Oct.	[illegible]
Feb.	0.746	May	1.853	Aug.	1.453	Nov.	[illegible]
March	1.440	June	1.830	Sept.	2.193	Dec.	[illegible]

Usually in temperate regions the greater portion of the rain falls in the autumnal months, and until the rivers have been filled by them the cold weather of winter rarely sets in. Excessive rains occasionally occur even in regions where moderate rains only prevail, and a large portion of the year's supply has been known to fall in the course of a few hours. At Catskill, N. Y., on July 26, 1819, the extraordinary fall of 18 inches occurred in 7½ hours. ("American Journal of Science," vol. iv.) In a day and night, Oct. 25, 1822, a fall of rain at Genoa amounted to 32 inches. At Joyeuse in the S. of France, Oct. 9, 1827, in 22 hours the fall amounted to 31 inches. But in the tropics such excessive floods are not so rare. In the month of July, 1825, nearly 69 inches fell at Aracan in Burmah, lat. 20° 20', and in August about 42 inches; and at Cayenne, lat. 4° 56' N., as stated by Capt. Roussin, there fell 151 inches from the 1st to the 24th of Feb. 1820. From such extraordinary rains there result disastrous floods, accounts of which are recorded in the annals of most countries as having occurred at intervals from very remote times; and on the other hand much more disastrous effects are recorded as occurring from droughts, the result of long continued want of rain.—As rain is a product of distillation, carried on by nature, the water that falls should be pure unless it meets in its progress to the earth foreign substances which it may take along either mechanically or in solution. The carbonic acid of the atmosphere, and ammonia also which often exists in the air, are the most frequent impurities present in rain, both which, if at all objectionable, are expelled by boiling. Nitric acid is sometimes detected in it, particularly in thunder storms, and is supposed to be a product of the combination of the nitrogen of the ammonia with oxygen of the air, the union induced by the electrical discharge. Many instances are recorded of solid bodies common to the earth being brought down by the rain, such as fish, frogs, a great variety of vegetable substances, as pollen, &c., and also mineral substances. All these, it is now well understood, are first raised up by whirlwinds or water spouts, and being carried by the rush of the winds to such distances as these are capable of supporting them, they then fall to the earth by their own gravity.

RAIN CROW, or RAIN BIRD. See CUCKOO.

RAIN GAUGE. For ascertaining the amount of rain which falls upon any locality, instruments are employed called rain gauges, ombrometers (Gr. ὄμβρος, rain, and μέτρον, measure), or pluviameters (Lat. *pluvia*, rain, and *metrum*, a measure). For a rough estimate any cylindrical vessel, as a tub, presenting equal areas at all points, might answer this purpose, the depth of water that falls being measured before any material diminution could have occurred by evaporation. But beside this source of error another is involved (from which indeed most of the rain gauges in use are not free) in the mouth of the vessel being formed of vertical sides, against which the winds that often accompany showers cause eddying currents of air, which seriously affect the amount of rain received in the aperture. To guard against the loss by evaporation, funnels are employed to receive the rain and convey it into some narrow-necked vessel beneath, which may be graduated either upon its own surface, if of glass, or upon an upright glass tube, connected at bottom with the receiving vessel, so that the water shall stand at the same level in both; and the divisions of the scale should be such that the unit may represent a quantity equal to the capacity of the mouth of the funnel and one inch depth. The funnels are commonly made of the area of 100 inches. The apparatus adopted by the Smithsonian Institution consists of a water-tight cask sunk in the ground to within 3 inches of its upper edge; this is covered with boards, which slope away from the centre and project a foot or more beyond the barrel, and over the boards are placed sods to imitate the natural ground. In the centre is left a circular aperture for the funnel, which is secured by two "clasps" to the board cover. The funnel projects a few inches above the cover, and is smaller at the mouth, which presents an area of 100 inches, than it is at the level of the cover. The sides are thus sloped outward down from the mouth to lessen the influence of eddying currents. At the bottom of the barrel is placed an earthen jug, into the mouth of which is introduced the spout of the funnel, exactly filling the opening. Two graduated measuring glasses are also kept in the barrel, inverted upon two long wooden pins set in the bottom. To determine the amount of rain that has fallen, the funnel is lifted out, and then the jug and the measuring glasses. The divisions of the larger one containing each a cubic inch of water, every one of these represents $\frac{1}{100}$ of an inch fallen into the rain gauge, and they are large enough to admit an approximate estimate of the thousandths, which, however, can be exactly measured by the smaller glass, that is graduated for this purpose. It is sometimes desirable to try the rain gauge upon elevated situations. Whenever this is done upon a roof, it should be placed several feet above the top and away from corners and the edge. In some of the observations made in Europe with the rain gauge, a singular difference has been noticed in the quantity of rain which falls at different elevations in the same locality. For a period of 12 years at the observatory at Paris the excess of rain falling in the court over that falling on the terrace, 92 feet above this, was estimated to amount to about ⅛ the larger quantity; and from similar observations in England it appeared to be established that the quantity received at the lowest levels was always greater than that in superior elevations. This was accounted for on the supposition that the lowest strata of air were highly charged with moisture and added their quota to the rain drops until these reached the earth. Prof. A. D. Bache threw much doubt upon these conclusions by his experiments in Philadelphia in 1833, in which he proved the extraordinary influence of the currents of air deflected from the walls of buildings in modifying the amount of water received in the rain gauge. This was strikingly exhibited in trials made upon the top of a shot tower 162 feet high, the rain collected at the same time at the different angles varying greatly in quantity. In general the gauges to leeward received more rain than those to windward; and in one extreme case the quantity collected at the S. E. angle was 2¼ times that at the N. W. angle.

RAINBOW, a circular arch of variously colored light, visible usually on a portion of sky overspread with falling rain drops, and in its ordinary forms always opposite to the place from which the sun or moon is shining at the time. When the field of falling drops is large, and the illumination thrown on it is bright, a second bow, exterior to and concentric with the first, appears. The inner, or most usual, is termed the primary, the outer the secondary bow. Each shows the same colors, and in the same succession, as those obtained in decomposing a beam of sunlight; the difference being, that the spectrum constituting the rainbow may be regarded as wonderfully extended on both sides, and curved into a circular form. In fact, the bow is always part or the whole of a complete circular spectrum; and it can be exactly imitated by passing an intense beam of light through the entire refracting edge or angle of a circular glass prism, and receiving the miniature rainbow thus formed on a white screen. The eye, however, does not readily discern in it all the prismatic colors, the breadth being limited, and the gradation of colors quite insensible. In the two bows, the colors lie in opposite order; in the primary the red is outermost; in the secondary it is innermost. The primary is always the brighter, and distinctly the narrower. When the light is abundant, this bow is often accompanied with successive bands of red and green, lying just within it or overlapping its violet edge, concentric with it, though usually through parts of its course only, and especially where it nears the horizon. These are called supernumerary bows. The writer has observed one distinct red and green band, and very bright, lying within the primary bow and continuous through its whole extent, when, the sun having nearly set, the bow had risen to near its greatest altitude. The common centre of the two bows is always in the straight line, prolonged, that passes through the centre of the sun and the eye of the spectator; so that, of course, the rainbow rises at the same rate as the sun declines, and declines if, the time being morning, the sun is rising. —The conditions requisite to produce the rainbow have been in a general way understood from an early period, though its causes were not so. The earliest known attempt at an explanation of it is that of Aristotle. He observed that from a glass globe filled with water and set in the sun, certain colors were always returned at certain angles with the course of the sun's beams; and he properly explained the circular form of the bow, by saying that if the sunbeam passing through the observer's eye be taken as an axis, and the globe be revolved round this axis, and at the same distance from it in all parts of its course, the same colors, preserving their angle with the direction of the sunbeams or of the axis, would be visible throughout all parts of this course; and hence it follows that a rainbow would result if there were globes enough, and so placed as to reflect colors at the same time from all parts of an arc of such a circle. The colors, however, were supposed to be merely reflected from the globe, or (in the sky) from the drop of water, until Fleischer of Breslau (1571), concluding that reflected light does not give colors, stated as a consequence that the rays must enter the drop. Of the light falling on the presented side of the drops, of course part will be reflected, but another part will enter and be refracted at the same time; striking on the inner opposite surface of the drop, part of this beam will emerge and escape, while another part will be reflected; and on again striking the side of the drop toward the spectator, though a portion of the residue of the first beam undergoes a second reflection, another portion emerges, again refracted, and, if at a proper angle, then passes to the eye. Kepler agreed in this view, but erred in supposing the entering light to be that of rays grazing or tangent to the upper sides of the drops. Antonio de Dominis, in 1611, carefully repeated the experiments with the glass sphere filled with water—these being easily performed, and showing in sunlight very vivid colors at great distance, and each at an angle of its own. Newton, however, gives to De Dominis undue credit, and unquestionably through his jealousy of Descartes, who in fact completed the explanation of the rainbow, with the exception of a single link, finally added by Newton himself. Descartes showed: 1, why there must be on the illuminated field of falling drops a circular belt of colors bright enough to be seen, and always of a definite diameter; and 2, that the colors are in separate bands or stripes in this, because they are not equally refracted. He gave the reasons why the colors must be just where they were, and in bands just so broad, if they all appeared; he could not tell why they all must appear. This element Newton supplied, when he discovered (1672) that sunlight is decomposable into a fixed number of different colored rays, refracted or bent at the same time in different but definite degrees, so that they must appear, under given circumstances, separated just so much, and always in the same successive order. This result will follow, then, whether sunlight is dispersed by prisms, or by transparent spheres, as water drops are. The mathematical theory, which belongs to Descartes, may be found in the higher text books of optics. It is very clearly stated in Olmsted's "Philosophy" (revised ed., New York, 1869). It will be proper to give a brief outline of it in this place. If a ray of light pass through the centre of a sphere or drop, its course is in an axis of the sphere or drop; it is not refracted. A ray parallel with this, and very near it, is refracted within the drop, toward the axis, but very slightly. Other rays, further and further from the axis, are refracted more and more toward it, but yet so as to fall, by lessening degrees, further from it on the inner or second surface of the drop; until, as Descartes proved, a ray entering the upper side of the drop, when this is above the eye, and at a point on it distant by an arc of 59° from the axis, will strike, on the inner surface, as far as any ray can do from the axis; the rays incident at greater arcs than this, up to 90°, deviating again toward the axis. Of course, near this limit, the deviation is very slight for rays coming on either side, so that much more light within the drop will be accumulated just at this point of the second surface than at any other; and though part of it emerges here, a sufficient quantity is reflected, and that in rays which preserve a parallel course after leaving the drop in the direction toward the spectator, to form a compact, parallel beam, bright enough to affect the eye at a great distance. Light falling on other parts of the drop is reflected, transmitted, or refracted so irregularly, that it is diffused and feeble, and but slightly affects the eye. Now all the rays thus entering the upper or outer sides of myriads of rain drops are sensibly parallel with a ray or line—the axis of the bow—from the sun's centre through the eye of the spectator. Calculation shows that the angle which the compact and visible emergent beam of red rays will make with the incident sunbeam, and hence with the axis of the rainbows, or line through the eye, is 42° 2′; that for the violet light 41° 17′; the other colors being at angles between these. Hence, all the other colors must be seen, in their order, upon drops lower and lower down, compared with the place of the red band; and the breadth of this bow will be 1° 45′. If, now, these rays, coming to the eye at such angles with the axis or course of a sunbeam at the time, be for the moment imagined to be inflexible wires, reaching from the eye out to the cloud, and (remembering that the angles must continually be the same) be revolved completely round the axis of the bow, there will result a complete circle, the larger portion of it usually below the horizon; the part above the horizon, and so visible, is the primary bow. The explanation of the secondary bow is in principle the same, with the difference that this is formed by light entering the drops near their lower side, or that toward the axis of the bows, which undergoes two reflections and emerges from the upper near side of the drop toward the spectator. The rays that can still, after two reflections, emerge in a parallel and relatively bright beam, have also their limit of divergence within the drop; and they are those entering at an arc of 71° and 72° from its axis; when they emerge, the angle the compact red beam makes with the axis is 50° 57′; the other colors following in order to the violet, whose angle is 54° 7′. The breadth of this bow is thus 3° 10′. The colors are reversed because the rays under two reflections have been made to cross themselves. The bow is more faint, in part owing to its greater width, and in part to loss of light by an additional reflection. The breadth of the space between the two bows is 8° 55′. But though the angles stated above for the primary bow are those of the greatest deviations for the red and violet by one reflection, yet, within 41° 17′, all the colors may emerge, and do so, though in more feeble degrees, at all angles down to 0°. Again, while the angles given for the secondary bow are those of least possible deviation within the drop, yet in a more feeble degree all the colors may emerge at all angles from 54° 7′ up to 180°. The consequence is, that the whole visible sky, if the whole could be overcast with drops, save the point at which the sun shone, would be faintly lighted up with white light, save the bows themselves, and the space between them; and from this last space all light would be excluded. And it is easily observed that this belt of sky between the two bows is quite dark, while within the inner and without the outer bow a diffused illumination really exists. Thus, rainbows are the colored borders of illuminated segments of the sky; or they are concentric hollow cones of colored light, the intersections only of whose bases by the plane of the falling rain appear visible to us. A third or "tertiary" bow, due to three reflections, and situated on the side toward the sun, at an angle of 40° 40′ from it, may be formed; but from its extreme faintness and unfavorable position, it is but seldom seen. It is stated that with a cylinder of water within glass, the bows have been distinctly traced and measured, growing successively broader and fainter, up to the 15th order.—From the above explanation, the following consequences are obvious: that the ordinary rainbows must be on the side of the observer opposite the sun; that their centre must be in that line already described as the axis; that they must move with the motion of the sun, declining in the morning, and rising if seen at evening; that when the sun and the observer are both in the same horizontal plane, as at sunset, the bows will be semicircles, and their altitudes then about 42° and 54°; that they can never approach nearer than this to the zenith, unless the observer be on an elevated position, so that the sun can shine from below the horizontal plane in which he is; that at the tops of high mountains they may be seen as complete circles; and that, to one at the ordinary level, in the low and middle latitudes, they are never seen between about 9 o'clock in the morning and 3 o'clock in the afternoon; while in higher latitudes, where the sun is often very low in the sky, they may occur even at midday. If the rain is near, the bows may sometimes be seen prolonged upon the landscape. The small water drops constituting spray may afford a rainbow. Hence, it is seen in the mist arising near cataracts, and, because near, is then small, and may appear as a complete circle. A partial bow may be observed in the mist created by whirling a wet broom; in the spray driven by the wind from the crests of waves; in that thrown up by the paddle wheels of steamers; and at times in drops of dew or rain upon herbage or grass. The formation of the supernumerary bows was explained by Young (1804), as due to interference of sets of rays emerging at angles very nearly those of the proper colors of the bows. Biot, and afterward Brewster, have shown that the light of both the bows is polarized in a plane cutting the sun and the eye, hence polarized by reflection.—The lunar rainbow is usually single, the primary bow only, and is often white; when colored, it is but faintly so. Very rarely, also, the solar rainbow is produced on cloud, *i. e.*, on vesicular drops, when it is called a "fog-bow;" and its diameter is variable, sometimes 34°, but always less than that of the proper rainbow. Col. Sykes ("Philosophical Transactions," 1835) saw such a bow from the top of a precipice 2,500 feet high, among the Ghauts, formed upon a fog cloud, while the sun behind him was low. It was near to him, a complete circle, apparently not more than 50 or 60 feet in diameter, and of most vivid colors; and in its centre, as in a splendid frame, appeared distinct images, in shadow, of himself, his companions, and horse. An outer faint bow was also seen. At another time, in India, he saw a bow upon a fog bank, perfectly white. Such a bow was once observed by Niebuhr, and once by M. St. John.

RAISED WORK IN METAL. Hollow articles in sheet metal, as tea and coffee pots, crucibles, thimbles, covers of vessels, &c., are generally produced from flat sheets, raised into the required forms by a variety of methods. One of these for articles only partially hollowed out, which are to be produced in great numbers, is by means of dies made of hardened steel, into which the metal is forced by a succession of blows from a drop hammer. These may be applied upon an upper hardened die having the same figure in reverse, and thus exactly fitting into the lower one. By this process, known as swaging, the gold plates for artificial teeth are formed between dies of lead and zinc. (See DENTISTRY.) For more complicated work, requiring a slowly progressive adaptation of the metal to the irregularities of the dies, several sheets are laid one upon another between them, and after each blow the bottom plate is taken out, and a fresh one is put in at top. Each plate is afterward finished singly by being struck into the die; and if the metal is not sufficiently ductile to take the shape without tearing, it must be annealed, a process which in many operations of this character requires to be several times repeated. Thimbles are struck between conical-shaped dies, of which several pairs are used, each successive pair approaching more nearly the final form. The metal may require several annealings in the process.—Another method which is practised for such hollow articles as tea pots, deep pans, crucibles, &c., is that known as spinning or "burnishing to form." In this process the disk of metal is held between two blocks applied to its centre, and secured to the mandrel of a lathe so as to revolve with it. A smooth, hard steel rounded point held in a rest is then pressed against the middle portion of the disk as it revolves, and a wooden rod at the same time is held against the edge on the opposite side of the disk to regulate the form into which the metal is bent back. The shape is also controlled in part by that of the block against which it is bent, and which thus serves as a mould. When the sides have thus been bent to fit this block, the piece is taken off from the mandrel, and if the article to be made is a tea-pot of which the neck is to be drawn in, a plain cylindrical block of the diameter of the required neck is substituted, and the partly hollowed sheet is attached to this as it was to the other. Being again made to revolve, the edge is turned down to the cylinder by means of burnishers of proper shapes, leaving the neck of its full size; and with a hooked stick the extreme edge is made to turn back and curl into the hollow bead which gives the finish and stiffness to the mouth of the vessel. Sometimes a mould is employed of the exact shape of the interior, formed of several pieces, which can be fitted together after they are introduced into the vessel, in the same way that the parts of a hat block or boot tree are fitted. The spinning process is very expeditious, and when uniformly conducted the form is perfect. For merely turning up the edges of metallic sheets machines are employed by silver and tin smiths, which, on turning a winch with one hand and holding the disk with the other, take the edge of the disk between two wheels and by one revolution bend it into the required form.—A third method of raising the surface of metallic disks is by the hammer; and by this means the largest vessels constructed by the coppersmith are fashioned, as the great pans and stills of many hundred pounds weight each used by the sugar refiners. The method is also applied by silver smiths to shaping most of the hollow articles of their manufacture. The action of the hammer is really like that of the burnisher, the blows being applied in successive circles round the metallic sheet, with the object of regularly approaching the desired end. Various sorts of hammers are used with faces specially adapted for the sort of curved surface to be produced, and the anvil or bed upon which the articles are supported is shaped with reference to the same object. Every blow given with the hammer is either intended for stretching the sheet, as when it strikes fair upon the metal, then supported upon a full bearing surface, or it is intended to bend it, when it rests over an edge of the anvil, or is placed over a cavity into which it is to be driven by swaging. It is extraordinary with what accuracy this work is conducted; thus a skilful workman knows exactly the size of the disk which will suffice to produce any required object without any deficiency or excess. For example, in making a hollow ball 6 inches in diameter, 2 disks of copper are required, each of 7½ inches diameter, or (roughly estimated) 23½ inches circumference. Each one is to make one of the hemispheres of the ball. By hammering judiciously the diameter of the disk is increased by this stretching or hollowing out of the sheet to 9 inches, while the circumference at the same time becomes contracted to 18 inches, which gives the required diameter of the ball. The great art of the workman consists in correctly estimating these effects and bringing out the result in a sheet of uniform thickness and with the least possible number of blows. In articles of complicated figure it is evident that long practice is required to attain this skill; and the methods are of a nature impossible to explain without the aid of illustrations. Reference may be made to Holtzapffel's "Mechanical Manipulations," vol. i. p. 398, where the subject is fully treated. A remarkable example of this kind of work is the ball and cross of St. Paul's cathedral, London. The copper ball is 6 feet in diameter and ⅛ inch thick, and is raised in two pieces only. The metal was first thinned and partly formed under a tilt hammer at the copper mills, and sunk in a concave bed; the raising was effected with hammers but little larger than usual; the two parts were riveted together in their place, and the joint is concealed by the ornamental band. The work on the cross also is hammered up. The consoles beneath the ball are of gun metal. The whole height of this metallic structure is 29 feet, and it contains 3¾ tons of copper, beside about 2 tons of iron used in framing and bracing within. In the gilding 33 ounces of gold were used.—Raised work in the precious metals is called chasing, and is effected by hammering, by punches, &c., furnished with grooves, and burnishing tools. (See Enchasing.)

RAISIN (Fr., a grape), the dried fruit of the grape vine. In various countries where the grape is largely cultivated, and especially in the regions around the Mediterranean, the fruit, after ripening, is dried either in the sun or in ovens, and is then packed in boxes or casks for domestic use and foreign export. It has long been a commercial product of no small importance. The varieties recognized in trade are not very numerous, but their differences from each other are strongly marked. These arise not merely from the original differences in the grapes, but also from the methods of drying. Among the best sorts are those known as the Malaga, Muscatel, or "sun raisins." These are dried upon the vines, the stem of each bunch when ripe being partially severed, and the leaves that shade it being picked off. Thus exposed, the grapes soon shrivel by the evaporation of the water they contain, and become sweeter by the consequent concentration of the pulp. When dried the bunches are taken off and carefully placed in boxes with sheets of paper separating the layers. These raisins, better than any other sort, retain the freshness and bloom of the fruit, and acquire less of the saccharine deposit which is found upon most of the other varieties. Other raisins are prepared by drying the ripe grapes after they are picked, either in the sun or in heated rooms, and while they are drying sprinkling an alkaline lye over them. The effect of this is to cause a saccharine exudation to take place, which forms concretions upon the raisins and coats them with a thin varnish. The raisins known as *lexias* are so called from the lye employed, and include the varieties called Valencia and Denia. The best of these are hung on lines to dry in the sun, and as they begin to shrivel they are dipped in the lye once or twice and hung up again to complete the drying. Of Turkish raisins two varieties, the sultanas and black Smyrnas, are the best known. The former are from a small delicious grape without seeds, and come packed in drums. The latter are also small raisins, but have very large seeds. They are generally free from the sugary concretions which are common to the other sorts.—A very important variety of raisins, and one rarely understood to be the fruit of the vine, is the "dried currant" of commerce. This is a very small-sized grape, largely cultivated at Patras, in Zante, Ithaca, and Cephalonia, and in the Grecian archipelago; its name is a corruption of Corinth or Corinthian grape. The grapes are no larger than peas, and the bunches are only about 3 inches long. They are laid up to dry in the sun, in heaps called *couches*, and are then deposited in large quantities in rooms called *seraglios*, where the masses become so compact from the sticky quality of the sugar which exudes from them, that they have to be forcibly dug apart for packing. For shipment they are placed in casks, and made into a solid mass by treading. The demand for these is very large in the United States.—Raisins are sometimes employed instead of grapes in the manufacture of wine, and among the ancient Romans and Greeks some of the best wines were of this character. Malaga wine has also been produced in this manner, and the Hungarian Tokay is made from half-dried grapes.—The importation of raisins into the United States during the year ending June 30, 1869, amounted to 54,448,630 lbs., chiefly from Spain, valued at $1,429,950; and of currants, 7,149,362 lbs., chiefly from England, Greece, and Austria, valued at $319,320.

RAJAH, a Sanscrit word signifying king, and applied to many princes, rulers, and petty chiefs of Hindostan, the countries lying E. of the bay of Bengal, various islands in the Indian ocean, and throughout the Indian archipelago.

RAJAHMUNDRY, a province of British India, presidency of Madras, bounded N. by Orissa, N. E. by Vizagapatam, S. E. and S. by the bay of Bengal, W. by Masulipatam, and N. W. by the territory of the Nizam; area, 4,501 sq. m.; pop. 1,012,036. The coast is low, and the port of Coringa is considered one of the best upon the E. shore of Hindostan. The only river of importance is the Godavery, which enters the province from the N., and after flowing about half its length divides into two branches, one of which runs S. and S. W. for 45 m., and the other S. E. and E. for 52 m., forming a delta that contains some of the most fertile land in India. The water of the Godavery is used for irrigation, and the river itself is navigated by boats and small steamers for some distance into the interior. In the neighborhood of the coast the surface is level and the soil for the most part fertile, but the N. and N. W. portions are hilly. The principal crops raised are rice, tobacco, indigo, cotton, maize, millet, various kinds of pulse, oil seeds, and sugar cane. Many cocoanut and other palm trees grow in the sandy soil along the sea shore. Cotton goods in imitation of those of Europe and America are successfully made at Samulcottah, and ship building is carried on to a considerable extent at Coringa.—RAJAHMUNDRY, the capital, is situated on the left bank of the Godavery, 265 m. N. E. from Madras; pop. about 20,000. It has a fort with mud walls.

RAJPOOTANA, RAJASTHAN, or RAJPOOT STATES, an extensive territory of Hindostan, bounded N. E. by the British districts of Butteeana and Kurreeana, and the native state of Jhujhur; E. by Goorgaon, Bhurtpoor, Dholpoor, and Gwalior; S. by the province of Omutwara, the territories known as Sindia's, Holkar's, and the Guicowar's, by Jaboah, and Myhee Caunta; W. by Sinde; and N. W. by Bhawulpoor. It comprises the British districts of Mairwarra and Ajmeer (area, 2,800 sq. m., pop. 262,000), and the native states of Alwur, Banswara, Bikaneer, Doongerpore, Jessulmeer, Joodpoor or Marwar, Jeypoor, Jhallawar, Odeypoor or Mewar, Tonk, Serohee, Kerowlee, Kishenagur, Pertaubgheer, Kotah, and Boondee (area 116,000 sq. m., pop. 7,560,000). The Aravulli mountains stretch across Rajpootana in a N. E. and S. W. direction. The greater part of the country lying W. and N. W. of this range is a sandy waste presenting an aspect nearly similar to the most desert tracts of Arabia and Africa. Oases occur at intervals, in the largest of which are the towns of Bikaneer, Joodpoor, Jessulmeer, Nagore, and Chooroo. The river Chumbul flows along the S. E. frontier, and the Lonee has a course of about 200 m. toward the S. W., where it is lost in the Runn of Cutch. S. E. of the Aravulli mountains there are several small lakes; and in many places abundant crops are raised by irrigating the sandy soil with water taken from the lakes or drawn from wells, some of which are 200 feet deep. Wheat, cotton, barley, millet, inferior opium, tobacco, sugar, and indigo are cultivated in different localities. Cloth, swords, and firearms are manufactured. —The inhabitants consist principally of Rajpoots, who are Hindoos, and of Mohammedans. The remainder of the population is made up of Bheels, Jains, Jauts, and Mairs. The Rajpoots, by far the most numerous, are supposed to be descended from the Kshattriyas, one of the 4 original castes into which the Hindoos were divided. Their empire appears to have been most powerful about the end of the 12th century, when Delhi, Ajmeer, Kunnouj, and Guzerat formed parts of it. In 1193-'4 they were several times severely defeated by the Mohammedans. In several other parts of India, as in Bundelcund, Rewa, Cutch, and Gurhwal, the race is still met with. They are all soldiers; each division has its military leader, and each forms a separate community. Some of the Rajpoot states became connected with the English East India company early in the present century, and since then the others have submitted to British protection.

RÁKÓCZY, a princely family of Transylvania, distinguished for its opposition to the house of Austria, and several members of whom were princes of Transylvania. Its most celebrated member was FERENCZ II., born in 1675, died in the castle of Rodosto in Turkey, on the sea of Marmora, April 8, 1735. After the death of his father and the surrender of Munkács after a 3 years' heroic defence by his mother, he was brought up under the care of the Austrian court, and during the insurrection under Tökölyi was placed under the Jesuits in Bohemia, who strove in vain to induce him to change his religion. Subsequently he received part of the Hungarian estates of his relatives, and was permitted to reside in that country. The disgrace of his family and the degradation of his country had sunk deep into his mind, and, accused of being engaged in a conspiracy to excite rebellion, he was taken in May, 1701, to Austria, and confined in the same dungeon at Neustadt from which, 30 years before, his maternal grandfather, Peter Zrinyi, had been taken to the scaffold; but he succeeded in escaping from confinement, and fled to Poland, where he remained a year and a half. Here he completed his arrangements with the disaffected Hungarians, and in 1703 suddenly appeared in the vicinity of Munkács, collected an insurrectionary band, and on June 7 issued a bitter manifesto against Austria. In this work he was supplied with money by France, then engaged in the war of the Spanish succession, and was so successful that after a short time he had almost all Hungary and Transylvania in his power, and even threatened Vienna. Negotiations were opened with the insurgents by the emperor Leopold I.

d his successor Joseph I., but, in spite of the ible moderation of Rákóczy, were all fruitless consequence of the high demands made by e more sanguine patriots. A diet was held Szécsény, and the revolted provinces and ties instituted a regular confederation similar those of Poland, Rákóczy, who had previously been elected prince of Transylvania, being trusted with the direction of the league with e title of *dux* (Hung. *vezér*). In Aug. 1708, e Hungarian leader while investing Trenthin was surprised and badly defeated by the strian general Heister, and Rákóczy himself caped with difficulty. From this time the ms of Austria were in the ascendant, and her ctories in the field were assisted by the dissensions which long before had manifested emselves among the confederates. Rákóczy ving gone to Poland, in order to meet with ter the Great of Russia, a peace was concluded in his absence between Austria and the confederates at Szatmár in Jan. 1711. Rákóczy ent first to France, in 1718 repaired to Spain, d from that country went to Turkey, and, companied by a number of his fellow refues, passed the remainder of his life at the cas of Rodosto. He wrote a narrative of the uggle in Hungary under the title of *Mémoires r les révolutions de Hongrie* (the Hague, 1739). e also composed meditations, hymns, soliloies, and a commentary on the Pentateuch. e name of Rákóczy has been given to the incipal Hungarian national march.

RÁKOS. See Pesth.

RALE, or Rasles, Sébastien, a French missnary to the North American Indians, born Franche Comté in 1658, killed at Norridgeock, Maine, Aug. 23, 1724. Having joined e Jesuits, he was engaged for a time in teachg Greek at a college in Nîmes. In 1689 he me to Quebec for the purpose of devoting mself to the Indians, and was stationed sucsively at the Abnaki mission of St. Francis ar the falls of the Chaudière, then in the Ilois country, and finally at Norridgewock on e Kennebec. He arrived here at least as rly as 1695. Most of the Indians were already Christians, and they even had a small urch in their village, where the missionary mained with the tribe during a part of each ar, accompanying them in all their hunt and fishing excursions, and winning their nfidence to such a degree that the Engh settlers ascribed their quarrels with the nakis to his influence. They accused him instigating the forays of the savages upon e settlements along the coast, and finally relved to destroy him, and set a price upon head. A party of New Englanders under pt. Hilton attacked Norridgewock in 1705, t withdrew after burning the church. A cond expedition in 1722 pillaged his cabin d the church, which had been rebuilt, but led to secure the missionary himself, who aped to the woods. Among the papers ich they carried off was his dictionary of the Abnaki language, which is now preserved in the library of Harvard college, and has been printed in the memoirs of the American academy of arts and sciences, with an introduction and notes by John Pickering (4to., Cambridge, 1833). In 1724 a party of 208 men from Fort Richmond surprised Norridgewock, killed a number of the Indians, and shot Father Rale at the foot of the mission cross, 7 chiefs who endeavored to protect him sharing his fate. His body was afterward disgracefully mutilated.—See a memoir of him by Convers Francis, D.D., in Sparks's "American Biography."

RALEIGH, a W. co. of Va., bordered E. by New river and drained by its tributaries; area, about 500 sq. m.; pop. in 1860, 3,367, of whom 57 were slaves. It has a mountainous surface, and in the valleys a fertile soil. The productions in 1850 were 40,511 bushels of Indian corn, 10,263 of oats, 2,890 of wheat, 4,929 lbs. of wool, and 21,289 lbs. of butter. Value of real estate in 1856, $510,260, showing an increase since 1850 of 112 per cent. Capital, Beckley.

RALEIGH, the capital of N. C. and seat of justice of Wake co., 6 m. W. from Neuse river, in lat. 35° 47' N., long. 78° 48' W.; pop. in 1860, 4,780. It is pleasantly situated on an elevation, and is very regularly laid out. In the centre is a park of 10 acres called Union square, from which extend 4 streets, 99 feet wide, dividing the city into 4 parts, in each of which is a square of 4 acres. The state house, one of the most splendid capitols in the United States, is built of granite, 166 feet long and 90 feet wide, surmounted by a dome, and surrounded by columns 6½ feet in diameter and 30 feet high. It is generally modelled after the Parthenon, and was erected at a cost of $500,000. The old state house, containing Canova's statue of Washington, was burned in 1831. Raleigh also contains a court house, gaol, 2 banks, 9 newspaper offices, 5 churches (Baptist, Episcopal, Methodist, Presbyterian, and Roman Catholic), and is the seat of the North Carolina institution for the deaf and dumb, and of a lunatic asylum. By the North Carolina railroad it has communication with all parts of the country; and the Raleigh and Gaston railroad connects it directly with Richmond, Va.

RALEIGH, or Ralegh, Sir Walter, an English courtier, author, and adventurer, born at Hayes, Devonshire, in 1552, beheaded at Old Palace yard, Westminster, Oct. 29, 1618. He was the son of a gentleman of ancient family, and was sent to Oriel college, Oxford, about the age of 16. He seems to have been distinguished in his studies, but he had been there hardly a year when he volunteered under Henry Champernoun, who commanded a small body of troops sent by Queen Elizabeth to assist the Huguenots of France. After serving about 6 years under Admiral Coligni, he proceeded to the Netherlands, and fought under the prince of Orange against the Spaniards. On his return to England he found people's minds filled with projects for colonizing the new world. His half brother, Sir Humphrey Gilbert, had just obtained a liberal patent (June, 1578) for establishing a plantation in America, and had little difficulty in persuading Raleigh to enter into the scheme. They put to sea in 1579; one of their ships was lost, the remainder, it is said, were crippled in an engagement with a Spanish fleet, and they returned without making land. The next year Raleigh distinguished himself in Ireland, where he held a captain's commission in the force employed in putting down the rebellion of the Desmonds. At the surrender of Smerwick he caused, under orders from his commander, several hundred Spanish allies of the Irish to be massacred. On his return to England, meeting the queen one day as she was walking, he spread his mantle over a wet place in the path for her to tread upon it. Struck by his gallantry, Elizabeth admitted him to court, loaded him with attentions, and employed him to attend the French ambassador Simier on his return to France, and afterward to escort the duke of Anjou to Antwerp. In her favor however he had a powerful rival in the accomplished Essex, and many romantic stories are related of the assiduity with which the two courtiers endeavored to supplant each other. Raleigh soon tired of an inactive life, and made use of his influence to promote a second expedition to America. Prevented by an accident from going in person, he left the command of the fleet to Sir Humphrey Gilbert, who sailed from Plymouth with 5 ships in June, 1583, and reached Newfoundland, of which he took possession in the name of the queen. One of his vessels had turned back when only two days out; another was abandoned at Newfoundland; a third was lost, with nearly 100 men; and Gilbert himself, on the voyage home, went down with one of the remaining two. Raleigh however was not disheartened. Obtaining from Elizabeth an ample patent and the title of lord proprietor over an extensive region, he fitted out two vessels under the command of Philip Amidas and Arthur Barlow, who reached Ocracoke inlet on the shore of North Carolina, July 13, 1584, and after being hospitably entertained by the savages on Roanoke island, and exploring Pamlico and Albemarle sounds, returned to England in September with the most glowing account of their discoveries. Elizabeth, as a memorial of her state of life, called the newly found region Virginia, and conferred upon Raleigh the honor of knighthood, with a lucrative monopoly of wines. Raleigh, now a member of parliament for Devonshire, obtained a bill confirming his patent, raised a company of colonists, and in 1585 sent out under command of Sir Richard Grenville a fleet of 7 vessels with 108 emigrants. The colony landed at Roanoke island about July 1, and Grenville soon afterward returned home with the ships, capturing on his way a rich Spanish prize. In the mean time Raleigh had been appointed seneschal of the [illegible] of Devon and Cornwall and lord ward[illegible] the stannaries, and had obtained a gra[illegible] 12,000 acres of forfeited land in Ireland, [illegible] he sold to Richard Boyle, afterward [illegible] Cork. His favor at court continued to in[illegible] and was even noticed on the stage in [illegible] which gave Elizabeth great offence. [illegible] the multitude he was one of the most [illegible] hated persons in England; and the elde[illegible] Burleigh, advising his son to avoid the [illegible] carriage of Raleigh and the dangerou[illegible] larity of his rival, urged him to "seek [illegible] be Essex and shun to be Raleigh." In [illegible] two parties were sent out to Virginia [illegible] enforcements, but they found the sett[illegible] abandoned. The disheartened colonis[illegible] gone home in Sir Francis Drake's ship, [illegible] fruit of their expedition had been little [illegible] than the introduction into England of [illegible] and potatoes. Banishing the visions of [illegible] and silver mines, in the pursuit of wh[illegible] many of the early American colonies we[illegible] stroyed, Raleigh now determined to fou[illegible] agricultural state, and in April, 1587, de[illegible] ed a considerable body of emigrants with [illegible] wives and families to make a settleme[illegible] Chesapeake bay. He granted them a [illegible] of incorporation, and appointed a mu[illegible] government for "the city of Raleigh," [illegible] ing the administration to John White, w[illegible] assistants. They founded their city not [illegible] bay, but on the site of the former settleme[illegible] Roanoke island, and when their ship re[illegible] sent Gov. White back to England to ex[illegible] reënforcements. But the reënforcements [illegible] came, and two ships which Raleigh se[illegible] with supplies fell into the hands of a Fr[illegible] man-of-war while they were looking for [illegible] Raleigh's means were now exhausted; the E[illegible] lish public were busied with other matters, [illegible] the colonists all perished, in what precise [illegible] ner is not known. Having expended [illegible] in his attempts at colonization, Raleigh in[illegible] formed under his patent a company of "[illegible] chants and adventurers" to continue [illegible] Meanwhile he had exerted himself to assis[illegible] preparations for resisting an expected Sp[illegible] invasion; and when the great armada appe[illegible] in the channel, he hung upon its rear in a ve[illegible] sel of his own, annoying it by quick and un[illegible] pected movements, which resembled, said [illegible] Henry Wotton, "a morrice dance upon [illegible] water." He was in Drake's expedition to re[illegible] Dom Antonio to the throne of Portugal ([illegible] and before his return captured some Spa[illegible] vessels intended for a fresh invasion of Engl[illegible] Visiting Ireland, he saw Edmund Spenser, [illegible] whom he had already contracted a friend[illegible] and brought him to Elizabeth's court to pr[illegible] to her majesty three books of the "Fa[illegible] Queen." He failed to procure for the poor [illegible] the substantial advantages which he cove[illegible] but he himself was loaded with favors. In [illegible] hope of shattering the power of Spain in the West Indies, he collected, mostly at his own xpense, a fleet of 12 vessels, with which he ailed from the west of England. With the ooperation of Frobisher he captured the larest Spanish prize that had ever been brought o an English port, but he seems to have done o more. Soon after this (1592) it was discovered that he had debauched one of the ueen's maids of honor, the daughter of Sir icholas Throgmorton; and though he maried the lady and lived with her happily till his eath, such an offence to her majesty, especially rom one who had been so long her own proessed admirer, was not to be overlooked. Imrisoned for two months and banished from ourt, he employed the period of his disgrace planning an expedition to Guiana in the ope of discovering the golden region of El orado. He set sail with 5 ships in 1595, and eturned the same year, after exploring a coniderable extent of country about the Orinoco nd destroying the Spanish settlement of San osé. His "Discovery of the large, rich, and eautiful Empire of Guiana," in which he pubished an account of this voyage, might almost e styled a spirited work of fiction. In the ollowing year he coöperated with Lord Howrd of Effingham, Lord Thomas Howard, and ssex in the capture of Cadiz, where he was ounded. His only reward was a restoration o the queen's favor. In 1597 he sailed under ssex against the Azores, quarrelled with his ommander, and returned to find the partial ailure of the expedition ascribed by the public o his misconduct. The court however judged ifferently. He had obtained a grant of the anor of Sherborne in Dorsetshire, which he agnificently embellished, was sent with Lord obham on a joint embassy to the Netherands in 1600, and on his return was made govrnor of Jersey. The execution of Essex, which e was supposed to have had an agency in ffecting, added greatly to the public odium ith which he was regarded, and the death f Elizabeth in 1603 proved a final blow to is fortunes. On the accession of James he as stripped of his preferments, forbidden the oyal presence, and shortly afterward arrested n charge of conspiring to place Lady Arabella tuart on the throne. He made an attempt, robably a feigned one, to commit suicide, delaring his persuasion that he was doomed to ll a victim to the arts of his enemies. Conicted on the slightest evidence, after a rancorus speech from Attorney-General Coke, who yled him a "damnable atheist," a "spider of ell," a "viperous traitor," he was reprieved nd sent to the tower, and his estates were iven to Carr, afterward earl of Somerset. uring the 12 years which he passed in confineent he composed his "History of the World" 1614), from the creation to the fall of the acedonian empire, a work greatly superior oth in style and matter to the English historical compositions which had preceded it. uring 5 years of his imprisonment his wife as permitted to bear him company. At last, Villiers having supplanted Somerset in the royal favor, Raleigh bribed the uncles of the new favorite to obtain his release, and he was accordingly liberated in March, 1615, but not pardoned. It has been supposed that the king had an eye to the possible profits of a fresh voyage to Guiana which Raleigh had proposed making, and to which he immediately devoted the remnant of his own and his wife's property. Obtaining from James a commission as admiral of the fleet with ample privileges, he fitted out 14 ships, and reached Guiana with the loss of two, Nov. 12, 1617. Keymis was sent up the Orinoco with 250 men in boats, landed at the Spanish settlement of St. Thomas, and, in defiance of the peaceable instructions of James, killed the governor and set fire to the town. Raleigh's eldest son was killed in the action. Unable either to advance or maintain their position, they retreated in haste to the ships, a Spanish fleet hovering near them, which had been informed of their intended movements. The leader of this unfortunate party committed suicide; many of the sailors mutinied; the ships scattered; and Raleigh landed at Plymouth in July, 1618, completely broken in fortune and reputation. He was immediately arrested, and failing in an attempt, by feigning madness, to escape to France, was committed to the tower. The Spanish ambassador demanded his punishment, and James was not reluctant to grant it. The judges deciding that, being still under judgment of death pronounced in 1603, he could not be tried again, it was resolved to execute the former sentence. From the moment that his fate became certain, the fortitude which had failed him on his arrest returned. On the scaffold he asked for the axe, and feeling the edge observed with a smile: "This is a sharp medicine, but it is a cure for all diseases."—Raleigh was a man of imposing person, dauntless courage, extensive knowledge, and varied accomplishments. His literary productions, beside those already mentioned, include some short poems, "Maxims of State," "The Cabinet Council," "The Sceptic," and "Advice to his Son;" and he is also remembered in the world of letters as the founder of the "Mermaid club." His life has been written by William Oldys, Arthur Cayley (2 vols. 4to., London, 1805), Mrs. A. T. Thomson (8vo., London, 1830), and P. F. Tytler (Edinburgh, 1833). His poems were collected by Sir E. Brydges (London, 1814), his "Miscellaneous Writings" by Dr. Birch (2 vols., 1751), and his "Complete Works" were published at Oxford (8 vols., 1829).

RALLS, a N. E. co. of Mo., separated from Illinois on the N. E. by the Mississippi and intersected by Salt river; area, about 450 sq. m.; pop. in 1860, 8,592, of whom 1,791 were slaves. It has an undulating surface and a generally fertile soil, underlaid by limestone. The productions in 1860 were 495,405 bushels of Indian corn, 61,427 of wheat, 49,608 of oats, 2,201 tons of hay, 20,366 lbs. of wool, and 78,274 of butter. There were 15 churches, and 1,428 pupils attending public schools. Capital, New London.

RALPH, James, an English author, born in Philadelphia, Penn., died in Chiswick, England, in 1762. He was a schoolmaster in Philadelphia, and went to England in company with Benjamin Franklin in 1724. In the first book of the "Dunciad" he is called one of Walpole's gazetteers. In 1728 he published a poem entitled "Night." He wrote "The Fashionable Lady, or Harlequin's Opera," performed in 1730, and altered several old plays. Most of his separate publications were political pamphlets on current topics. He attached himself to the faction of the prince of Wales, and Horace Walpole mentions his having, in June, 1753, "had the good fortune to be bought off from his last journal, 'The Protestor,' for the only paper that he did not write in it." His only political work now remembered is an octavo volume in answer to the duchess of Marlborough's "Account of her Conduct," in which he defended the memory of Queen Mary and Queen Anne. He continued anonymously Guthrie's history, under the title of a "History of England during the Reigns of King William, Queen Anne, and George I."

RAM, Battering. See Battering Ram.

RAMADAN (Arab., a consuming heat), the 9th month of the Mohammedan year, during the whole of which a rigorous fast is commanded by the Koran. No one is allowed food or drink from sunrise until the appearance of the stars; and those who are unable to observe the ordinance on account of sickness, must fast during the month immediately succeeding their recovery. The Moslems compensate themselves for this rigor during the day by feasting at its close, frequently carried to great excess and continued through the whole night; and Ramadan is succeeded by a month of feasting called the Bairam, the two corresponding to the Christian Lent and Easter. (See Bairam.)

RAMBOUILLET, a town of France, in the department of Seine-et-Oise, 32 m. S. W. from Paris; pop. in 1856, 3,022. It is situated in a fine valley, at the S. end of the forest of the same name. It contains a massive chateau, built in the shape of a horse shoe, protected by ditches and flanked with 5 strong towers, in one of which Francis I. breathed his last. It is surrounded by beautiful gardens planned by Le Nôtre and a large park and forest. In the park is a model farm established here by Louis XVI. in 1786, for the improvement of the breed of sheep, which in 1811 received the merinos that had been imported from Spain by Napoleon. The seigneury of Rambouillet was purchased in 1711 by the count of Toulouse, 3d son of Louis XIV. by Mme. de Montespan, and in 1714 was erected into a dukedom. In 1778 it was bought by Louis XVI.

RAMBOUILLET, Hôtel de, the residence of the noble family of Rambouillet, celebrated as the head-quarters of the highest fashio and literary society of Paris during the half of the 17th century. It was situated ly half way between the Palais Royal a Louvre, and was embellished, if not c built, by Catharine de Vivonne, marchi of Rambouillet, who soon made her dra room, known as the *chambre bleue d'Art* the centre of the most refined and brillia ciety of the capital. Here might be see highest among the nobility, as the pr of Condé, Charlotte de Montmorency, w daughter Anne Geneviève de Bourbon, a ward duchess of Longueville, and her so duke d'Enghien, afterward the great Co the most accomplished and virtuous lad the time, who were styled *précieuses*, the tess de la Suze, Mme. d'Aiguillon, M Sablé, Mlle. Scudéry, Mlle. Paulet, Mm Lafayette, and Mme. de Sévigné; and th celebrated wits and authors, including La R foucauld, Balzac, Voiture, Patru, Godea L nage, and St. Evremond. Here Malher poet, was respectfully welcomed in his years; here Corneille read his masterp *Le Cid*, *Horace*, *Cinna*, *Polyeucte*, and oth here Bossuet, scarcely 16 years old and pupil at the college of Navarre, preached first sermon; while Descartes' *Méthode* was received with applause and eagerly disc Such society could not fail to exercise a m influence, and it contributed greatly to th provement of the French language. Du its palmiest days, from 1624 to 1648, it considered the "oracle of good taste;" nicety gradually degenerated into fast ness, and its wit into mannerism and af tion. The *précieuses* fell into such dis that in 1659 Molière, who had just arrive Paris, satirized them in his little comedy *précieuses ridicules*. On the death of the m chioness in 1655, the *réunions* ceased. A interesting account of them was given by Rœderer in his *Mémoires pour servir à l'hi de la société polie en France* (Paris, 1835).

RAMEAU, Jean Philippe, a French mu composer, born in Dijon, Sept. 25, 168 in 1764. He was the son of an organis was educated for the bar; but he had no for any study but music, and at the age of went to Italy as a violinist, returned to P in 1717, and was organist in several churches. He composed anthems, cantatas, and pieces f the organ and the harpsichord, publish *Traité de l'harmonie* (1722) and *Nouveau tème de musique théorique* (1726), and c posed pieces of music for several of Pi light comedies. He wrote the music for V taire's *Samson* (1732) and Pellegrin's *Hip lyte et Aricie* (1733), the second of which w very successful. During the next 30 years he wrote no fewer than 22 operas, now obso and various theoretical works.

RAMILLIES, a village of Belgium, provi of South Brabant, 16 m. S. by E. from Louv pop. 400. It is famous for a victory wo the duke of Marlborough over the French during the war of the Spanish succession. Marshal Villeroy, a favorite of Louis XIV., but the most presumptuous and incapable of his generals, had placed the French army in such a position as to render defeat inevitable. The duke, at the head of the allied forces of the English and the imperialists, attacked him, May 23, 1706, and within a few hours secured a complete triumph. The loss of the French amounted to 5,000 killed or wounded and 15,000 prisoners, while Marlborough lost fewer than 3,000, and was enabled at once to take possession of Antwerp, Brussels, and Ostend.

RAMISSERAM, an island between Ceylon and the continent of India, at the W. extremity of the chain of rocks and sand banks, called Adam's Bridge, that stretch across from Ceylon and separate Palk's bay from the gulf of Manaar. The island is of irregular shape, about 12 m. long and 6 m. broad. The surface is generally low, and there are tracts of considerable extent covered by swamps. It is well watered, and there is a fresh water lake nearly 3 m. in circumference. It has on its E. side a town named Ramisseram, containing about 1,000 houses, and a magnificent pagoda built of immense blocks of granite; its inhabitants are principally Brahmins. The island is looked upon as a place of great sanctity by the Hindoos, and pilgrimages are undertaken to it from the most distant parts of India, the annual number visiting the great pagoda being estimated at 30,000.

RAMMOHUN ROY, rajah, a Hindoo scholar and reformer, born in the district of Burdwan, Bengal, about 1774, died near Bristol, England, Sept. 27, 1833. His family were strict Brahmins, but having studied the Koran he early renounced polytheism, and his father was compelled to withdraw his countenance from him, though he contributed secretly to his support. In 1803, after the death of his father, Rammohun Roy published several pamphlets in the native and foreign languages, to show that the Brahmins had fallen away from their original faith, for which an unsuccessful attempt was made to deprive him of caste. He translated into Bengalee and Hindostanee the Vedanta, or body of Hindoo theology as contained in the Vedas, afterward prepared an abridgment of it, and in 1816 translated the abridgment into English. In conjunction with two other natives he published the "Bengal Herald," an English newspaper, and in 1820 published in English, Sanscrit, and Bengalee a series of selections from the New Testament, entitled "The Precepts of Jesus the Guide to Peace and Happiness." In this he advanced Unitarian opinions which involved him for several years in controversy with Dr. Marshman and other missionaries. He believed in the divine mission of Christ, and considered Christianity consistent with Brahminism as it is in the ancient Sanscrit authorities. In 1830 he was accredited to the British court by the king of Delhi, to make a representation of grievances; and though not recognized officially, he was successful in his mission.

RAMORINO, Gerolamo, a military adventurer, born in Genoa in 1792, executed in Turin, May 22, 1849. He was a natural son of the French marshal Lannes, entered the ranks of the French army, and in the campaign of 1809 against Austria served as a common soldier, and in that of 1812 against Russia as captain of artillery. In 1815 the emperor appointed him officer of ordnance, and after the second restoration he retired to Savoy. During the insurrection which broke out in Piedmont in 1821, he along with the count of Santa Rosa placed himself at the head of the insurgent troops, and by a dexterous retreat from Casale to Alessandria saved them from being destroyed by the Austrians. After the failure of the movement he fled to France, and at the beginning of the Polish insurrection of 1830 hastened to Warsaw to offer his services. He was first made colonel, and then general of a corps with which he gained numerous advantages, and his success alone saved him from the condemnation of a court martial on account of his frequent disobedience of orders. After the fall of Warsaw he retired to the upper Vistula, refused the Russian summons to surrender, but finally crossed the frontier and laid down his arms in Galicia, whence he went to France. For a short time he served in the Spanish civil war, and in 1833-'4 engaged in the invasion of Savoy planned by Mazzini. After the failure of this expedition (see Mazzini) he went to Paris, where he lived in poverty and isolation until 1848, when he went to Italy to serve against Austria. At the beginning of Charles Albert's second campaign, in the following year, Chrzanowski placed him at the head of the 5th division, with orders to occupy a position on the right bank of the Po, and, should the enemy advance from Pavia, to cross the river and prevent his march. Ramorino, mistaking the design of the Austrians, commanded by Radetzky, acted directly contrary to his orders, and left the left bank of the Po undefended and the direct road from Pavia to Turin open. The fatal issue of the battle of Novara, March 23, 1849, was the consequence. For this conduct he was deprived of his command, and was suspected of treason. He retired to Borgomanero, which he believed or affected to believe was the head-quarters of the Sardinian army, but was arrested at Arona by the national guards, tried before a court martial on a charge of insubordination, and sentenced to death. He justified his course on the ground of the feebleness of his division, 6,000 strong, which rendered it impossible for him to resist the advance of the Austrian army. The sentence was carried into execution, although he stoutly maintained his innocence and died bravely.

RAMSAY, Allan, a Scottish poet, born in Leadhills, Lanarkshire, Oct. 15, 1686, died in Edinburgh, Jan. 7, 1758. His father, who was manager of the lead mines of Lord Hopetoun, claimed descent from the earls of Dalhousie, and collateral relationship with the Douglases, a circumstance referred to with considerable complacency by his son in various passages of his writings. Allan is said to have been employed when a child as a washer of ore, but he acquired a tolerable education at the village school of Leadhills, where he learned, among other things, to read Horace "faintly in the original." At the age of 15 he was apprenticed to a wig maker in Edinburgh, an employment in which he continued for several years after the expiration of his apprenticeship. His poetic talent did not develop itself until he was about 26 years old, and his first production in verse was an address "To the most happy Members of the Easy Club," a convivial association of Jacobites. As poet laureate of the club he produced a number of light and humorous pieces for their edification; and he subsequently published on single or half sheets many poems on local or familiar topics, which at the moderate price of a penny each found a ready sale among the citizens of Edinburgh, who were in the habit of sending their children with a penny for "Allan Ramsay's last piece." His first poem of considerable length was a continuation of King James's "Christ's Kirk on the Green," published in 1716, and of which in 1718 he published a second edition with an additional canto. A short time previous to the latter date he exchanged his employment of peruke making for the more congenial one of bookseller, and at the Mercury opposite to the head of Niddry's wynd he prosecuted his business, which included that of author and editor, with industry and success. In 1720 appeared a 4to. edition of his collected poems, which brought the author the very considerable sum of £400. Incited by this success, Ramsay produced in the course of the next few years a volume of "Fables and Tales," the "Fair Assembly," "Health," a poem inscribed to the earl of Stair, and the "Tea Table Miscellany," a collection of songs, Scottish and English, with many of his own composition, which was extended to 4 volumes. This was suggested by a volume of Scottish songs published by him in 1719, and was in such demand that in a comparatively short time it ran through 12 editions. In 1724 he also published "The Evergreen, being a Collection of Scots Poems wrote by the Ingenious before 1600," into which is introduced a poem by himself entitled the "Vision," a Jacobite allegory. His most important work was "The Gentle Shepherd" (1725), portions of which had appeared in his first volume of poems. He now removed his business to a larger shop, which soon became the resort of the wits and literary men of Edinburgh, and in which he established the first circulating library ever opened in Scotland. In an evil hour he was tempted into building at great expense a theatre, an enterprise which failed through the action of the magistrates, who enforced against him the act for licensing theatrical performances. By careful attention to his business he repaired his losses, and when near his 60th year built a house on the Castle hill, in which he passed the remainder of his life in easy circumstances. In 1728 he published by subscription a second volume of his poems in quarto (including "The Gentle Shepherd"), which proved equally successful with the first; and his entire poems were republished in London in 1731 and in Dublin in 1733. His last original work of importance was a collection of fables published in 1730. A complete edition of his poems, with a biography by George Chalmers, was published in 2 vols. 8vo. in 1800, and "The Gentle Shepherd" is frequently republished. A very correct edition was printed by W. Gowans (New York, 1854).—Allan, son of the preceding, a portrait painter, born in Edinburgh in 1713, died in Dover, Aug. 10, 1784. He was a man of literary culture, settled in London, and was a frequent visitor at the house of Dr. Johnson. Though raised by political partisanship to a momentary rivalry with Sir J. Reynolds, his works are not above mediocrity.

RAMSAY, Andrew Michael, better known by the name of the chevalier de Ramsay, a Scottish author, born in Ayr, June 9, 1686, died in St. Germain-en-Laye, France, May 6, 1743. He was educated at the university of Edinburgh, and in his 23d year, becoming unsettled in his religous convictions, he repaired to the university of Leyden to consult Poiret, a leading advocate of the mystical theology then popular on the continent. He next visited Fénélon at Cambray, and during a 6 months' residence in the house of the archbishop was by him converted to the doctrines of the Roman Catholic church, which he ever afterward professed. He mastered the French language, which he wrote with great purity, and through the exertions of Fénélon was appointed tutor to the duke of Château-Thierry and afterward to the prince de Turenne. Subsequently he had charge for a year at Rome of the education of the two sons of the pretender, Charles Edward and Henry, afterward Cardinal York. He revisited Scotland in 1725, and for several years was an inmate of the family of the duke of Argyle, and in 1730 he received the degree of LL.D. from Oxford university. His largest work is "On the Principles of Natural and Revealed Religion," published posthumously in 1749 (2 vols. 4to., Glasgow). His *Voyages de Cyrus*, by which he is best known, is a palpable imitation of the *Télémaque* of Fénélon. It has been frequently reprinted, the best edition in French being that of 1727 (2 vols. 8vo., Paris and London), and was translated by Nathaniel Hooke. He also wrote a biography of his friend and benefactor, Fénélon (the Hague, 1723), and one of Marshal Turenne, both of which were translated and republished in England. His renunciation of the Presbyterian creed, in which he had been strictly reared, severed completely his relations with his family, who refused to receive an annuity which he wished to settle on them; and it is said that his father, an old-fashioned Covenanter, indignantly declined a present of money from his son, exclaiming: "It cam' by the beast, and let it gang to the beast."

RAMSAY, DAVID, an American physician and historian, born in Lancaster co., Penn., April 2, 1749, assassinated in Charleston, S. C., May 8, 1815. He was graduated at Princeton college in 1765, studied medicine in Philadelphia, and in 1772 commenced practice in Maryland, whence in the succeeding year he removed to Charleston, S. C. He took the field as a surgeon at the outbreak of the revolution, was a member of the South Carolina legislature, and of the privy council or council of safety, and in the latter capacity became so obnoxious to the British authorities, that after the capture of Charleston he was included among the 40 inhabitants of that place who were held in close confinement at St. Augustine as hostages. In 1782 he was elected to congress from the Charleston district, and held for a year the office of president of that body. In 1785 he published his "History of the Revolution in South Carolina," and in 1789 his "History of the American Revolution." Both were republished in Europe, and were translated into French. In 1801 he published a "Life of Washington," and in 1809 a "History of South Carolina" (2 vols. 8vo.), founded upon a previous "Sketch of the Soil, Climate, Weather, and Diseases of South Carolina." His next production was a "History of the United States," from their settlement as English colonies to the close of 1808, which was published posthumously, with a continuation to the treaty of Ghent, prepared by the Rev. Samuel Stanhope Smith, in 1817 (3 vols. 8vo.). Another work upon a more comprehensive plan, which had engaged his attention at intervals during a period of nearly 40 years, was published in 1819 under the title of "Universal History Americanized" (12 vols. 8vo.). It purported to give a historical view of the world from the earliest records to the 19th century. Apart from his literary labors, he practised his profession with success in Charleston, and was engaged in many public proceedings of importance. He seldom devoted more than 4 hours out of the 24 to sleep; but notwithstanding this small allowance of time for rest, his health was vigorous. He was shot in the street by a lunatic, of whose mental unsoundness he had given evidence before a commission *de lunatico inquirendo.*

RAMSAY, EDWARD BANNERMAN, a Scottish author, born in 1793, was graduated at St. John's college, Cambridge, became incumbent of St. John's church in Edinburgh in 1830, and was appointed dean of the diocese in 1846. He is author of "Reminiscences of Scottish Life and Character" (Edinburgh, 1858), which passed through 8 editions in 2 years, beside 2 in America; a second series appeared in 1861. He has also written several theological and devotional works, as "Diversities of Christian Character" (Edinburgh, 1858), "Advent Sermons," &c.

RAMSDEN, JESSE, an English maker of philosophical instruments, born near Halifax, Yorkshire, in 1735, died in 1800. He first served an apprenticeship to a cloth dresser in Halifax, but his mathematical tastes led him afterward to bind himself to an instrument maker, and he early opened a shop of his own in London. He improved the construction of the sextant so as to reduce the limit of error from 5' to 30". The telescopes erected by him at the observatories of Blenheim, Mannheim, Dublin, Paris, and Gotha were remarkable for the superiority of their object glasses; and in his mural quadrants furnished to the observatories of Padua and Wilna, it was not possible to detect an error amounting to 2½ seconds. One of his most celebrated productions was a dividing machine of great perfection. (See DIVIDING ENGINE.) By his will a large portion of his fortune was distributed among the workmen whom he had employed.

RAMSEY, an E. co. of Minn., bordered S. W. and partly N. by the Mississippi, and drained by Rum river; area, about 2,800 sq. m.; pop. in 1860, 12,150. It has an elevated surface, with prairies and forests. Capital, St. Paul.

RAMSGATE, a seaport town of Kent, England, situated at the S. E. corner of the isle of Thanet, 67 m. E. from London; pop. in 1861, 11,838. The harbor is artificial, and nearly circular, comprising an area of 46 acres, and including a dry dock and ship railway. Ship building and rope making are carried on. Ramsgate is a dependency of Sandwich, and a fashionable watering place.

RAMUS, PETER (PIERRE DE LA RAMÉE), a French grammarian and logician, born in Cuth, Picardy, in 1502 or 1515, killed in the massacre of St. Bartholomew's day at Paris, Aug. 24, 1572. He was born of poor parents, and at the age of 12 entered the college of Navarre at Paris as a servant, spending the day in labor and a good part of the night in study. He made rapid progress, and conceived a great love for logic with a profound contempt for the way in which it was taught. When his course was finished, and he presented himself for examination for the degree of master of arts in 1536, he chose for his exercise the following subject: *Quæcunque ab Aristotele dicta essent commentitia esse* ("All that has been affirmed by Aristotle is a fabrication"). So bold a denial of the infallibility of Aristotle startled the judges, but the young candidate maintained his side with so much skill, that he was admitted to his degree. He afterward taught in the college of Ave Maria, and when about 28 years old published two works in Latin entitled respectively *Dialecticæ Partitiones ad Academiam Parisiensem*, and *Animadversiones in Dialecticam Aristotelis*. These books had scarcely appeared when they were attacked by the officers of the university of Paris, and an order for their suppression was obtained from the magistrates. The author was represented as impious and seditious, and as aiming to destroy all science and religion under the pretence of assailing Aristotle. The quarrel between the rival systems of logic was at last settled by the king, Francis I., who ordered a trial in which two of the judges were to be nominated by Ramus, two by Govea, his chief accuser, and one by the king. After a regular, though it is charged an unfair hearing, Ramus, on March 1, 1544, was condemned as having "acted rashly, arrogantly, and impudently," and was prohibited from teaching and his book suppressed. Soon after he lectured on rhetoric at the college of Presles, and in 1545 returned to Paris, where by the influence of the cardinal of Lorraine the royal prohibitory decree had been cancelled. Turning his attention to mathematics, he began a course, which was continued until 1551, when Henry II. appointed him professor of philosophy and eloquence in the college of France. During the 10 following years, which were the most tranquil of his life, he published a Greek, a Latin, and a French grammar, and treatises on mathematics, logic, and rhetoric. In 1561 he embraced Protestantism, and advocated his opinions with great zeal. In July, 1562, he was forced to flee, but was offered by Charles IX. a refuge at the palace of Fontainebleau, while his own house was pillaged and his library destroyed. In 1563, after the treaty of Amboise, he returned to Paris, and for a time occupied his professor's chair; but in 1568 he received permission to travel on account of the civil troubles. In Heidelberg he lectured on mathematics, and in Geneva and Lausanne on logic. His assassination on the night of St. Bartholomew was effected through the agency of one Jacques Charpentier, whose appointment to the chair of mathematics in the university he had opposed. His followers were called Ramists or Rameans. A catalogue of his works may be found in *Ramus, sa vie, ses écrits et ses opinions*, by Waddington-Kastus (8vo., Paris, 1855).

RAMUSIO, Giambattista, an Italian traveller and scholar, born in Treviso in 1485, died in 1557. He held many offices under the republic of Venice, was secretary of the council of ten, and travelled as an ambassador through France, Switzerland, and Italy. In 1550 he began to publish, under the title of *Raccolta di navigazioni e viaggi*, a collection of the most important voyages and travels to distant countries in ancient and modern times, which is of value to the American historian, as it possesses some relations of discovery and conquest of the new world, not elsewhere extant. Two volumes were published during his lifetime and a third after his death.

RANCÉ, Armand Jean Le Bouthillier de, the reformer of the monastery of La Trappe, born in Paris, Jan. 9, 1626, died Oct. 26, 1700. He was a godson of Cardinal Richelieu, and at the age of 12 published an edition of Anacreon, with notes and comments. Though a priest in 1651, he led a rather dissipated life, was an assiduous visitor at the Hôtel de Rambouillet, where he fell in love with the duchess of Montbazon. On her death some years [illegible] he turned his thoughts to religion, submitting himself to severe penances, gave all his property to the poor, and resigned all his benefices except the abbey of La Trappe, to which [illegible] retired in 1662. The disorders that prevailed here strongly impressed him with the necessity of a reform in monastic life, and he [illegible] twice to Rome in 1665 to obtain from the [illegible] permission to enforce in France the rule of the former "strict observance of Cîteaux." He failed in his mission, but nevertheless introduced the most rigorous regulations [illegible] his own community, and brought it back [illegible] its original severity. Rancé's doctrines were denounced, and in 1673 arbiters were appointed by the king, who came to no decision. In [illegible] he published a treatise *De la sainteté et des devoirs de la vie monastique*, and in 1690 assumed the spiritual direction of the convent of Les Clairets, a female community dependent [illegible] that of La Trappe, and composed his *Réflexions sur les quatre évangélistes*. In 1695, having brought on a severe disease by his austerities, he resigned his abbacy and remained a private monk in the convent, redoubling his penances, and finally breathing his last upon a bed of straw and ashes. His life was written by his contemporaries Maupeau, Marsollier, and Lenain de Tillemont, by Châteaubriand (Paris, 1844), and by C. Butler (London, 1814).

RANDOLPH, the name of counties in [illegible] the United States. I. A N. co. of Va., drained by the sources of the Monongahela river; area about 2,000 sq. m.; pop. in 1860, 4,990, of whom 183 were slaves. The surface is mountainous, a range of the Alleghanies running along its E. border, and several parallel ranges extending within its limits; the soil in the valleys is fertile. Coal, iron, salt, limestone, and other minerals abound. The productions in 1850 were 11,740 bushels of wheat, 87,46[illegible] of Indian corn, 44,789 of oats, 6,480 tons of hay, 1,844 lbs. of tobacco, 18,895 of wool, and [illegible] 889 of butter. There were 10 churches, and 880 pupils attending public schools. Value of real estate in 1856, $1,287,652, showing an increase since 1850 of 14 per cent. Capital, Beverly. II. A central co. of N. C., drained by Deep river and branches of the Yadkin; area, about 900 sq. m.; pop. in 1860, 16,7[illegible] of whom 1,645 were slaves. It has a diversified surface and fertile soil. The productions in 1850 were 83,364 bushels of wheat, 440,0[illegible] of Indian corn, 38 bales of cotton, and 1,915 lbs. of tobacco. There were 20 grist mills, a woollen factory, 5 cotton factories, 5 tanneries, 1 newspaper office, 49 churches, and 1,550 pupils attending public schools. Capital, Ashborough. III. A S. W. co. of Ga., separated from Alabama by the Chattahoochee, intersected by Pataula creek, and drained by branches of Flint river; area, about 700 sq. m.; pop. in 1860, 9,571, of whom 4,467 were slaves. It has a nearly level surface, and a very fertile soil in the river bottoms. The productions in 1850 were 454,583 bushels of Indian corn, 151,189 of sweet potatoes, 56,959 of oats, and 10,582 bales of cotton. There were 8 grist mills, 12 saw mills, 2 tanneries, 44 churches, and 715 pupils attending public schools. Capital, Cuthbert. IV. An E. co. of Ala., bordering on Georgia, intersected by the Tallapoosa river; area, about 600 sq. m.; pop. in 1860, 20,059, of whom 1,904 were slaves. It has an uneven surface and a generally fertile soil. Gold is found in the county. The productions in 1850 were 319,169 bushels of Indian corn, 60,820 of sweet potatoes, 7,185 lbs. of rice, and 1,056 bales of cotton. There were 40 churches, and 1,229 pupils attending public schools. Capital, McDonald. V. A N. E. co. of Ark., bordering on Missouri, and drained by Eleven Point, Big Black, Little Black, and Cache rivers, branches of Black river; area, about 850 sq. m.; pop. in 1860, 6,261, of whom 359 were slaves. Its surface is generally level and the soil fertile. The productions in 1854 were 202,018 bushels of Indian corn, 5,723 of wheat, 10,842 of oats, and 275 bales of cotton. In 1850 there were 8 grist mills, 10 saw mills, a woollen factory, and 3 tanneries. Capital, Pocahontas. VI. An E. co. of Ind., bordering on Ohio, and drained by White, Mississinewa, and Whitewater rivers; area, about 460 sq. m.; pop. in 1860, 19,016. It has an undulating surface and fertile soil. The productions in 1850 were 536,107 bushels of Indian corn, 67,048 of wheat, 75,290 of oats, 60,125 lbs. of wool, and 7,261 tons of hay. There were 32 churches. It is intersected by the Bellefontaine railroad line, which passes through the capital, Winchester. VII. A S. W. co. of Ill., separated from Missouri by the Mississippi river, intersected by the Kaskaskia, and drained by various small streams; area, about 500 sq. m.; pop. in 1860, 17,205. It has an undulating and hilly surface and a generally fertile soil. The productions in 1850 were 443,491 bushels of Indian corn, 60,914 of wheat, 125,130 of oats, 1,296 tons of hay, and 17,781 lbs. of wool. There were 12 saw mills, 2 tanneries, 3 newspaper offices, 24 churches, and 1,414 pupils attending public schools. Capital, Chester. VIII. A N. co. of Mo., intersected by the East fork of Chariton river and drained by Silver creek, the Elk fork of Salt river, and the head waters of Bonne Femme river; area, about 450 sq. m.; pop. in 1860, 11,406, of whom 2,619 were slaves. It has a nearly level surface and very fertile soil. The productions in 1850 were 668,105 bushels of Indian corn, 60,914 of wheat, 125,130 of oats, 2,263,796 lbs. of tobacco, 38,309 of wool, and 158,768 of butter. There were 9 saw mills, 6 tanneries, 14 churches, and 607 pupils attending public schools. The capital, Huntsville, is situated 78 m. N. W. of Jefferson City.

RANDOLPH, John, of Roanoke, an American statesman, born at Cawsons, Chesterfield co., Va., June 2, 1773, died in Philadelphia, June 24, 1833. His parents were of ancient and wealthy families, and on his father's side he was descended from Pocahontas the Indian princess—a descent in which he always took great pride. His early education was conducted at home, but about his 16th year he spent a few months in study at Princeton, and at Columbia college, New York. He studied law at Philadelphia, but never engaged in the practice of the profession. In 1799 he was elected a representative in congress, and soon became conspicuous, in the language of the historian Hildreth, as "a singular mixture of the aristocrat and the Jacobin: an aristocrat by birth, education, and temperament; a Jacobin at this time out of enthusiasm for France, and during all his life out of a sort of Ishmaelitish opposition to the exercise of authority by anybody but himself." In a debate, Jan. 10, 1800, on the army bill, he spoke of the officers of the army and navy as "a handful of ragamuffins," and was in consequence insulted at the theatre a few nights afterward by some young military officers. He wrote next day a violent letter to the president demanding the punishment of the offenders. The president referred the matter to congress, and an investigation was ordered, which resulted only in severe censure by a committee of Randolph's letter. He was reelected in the following year, and, there being a republican majority in the house, was made chairman of the committee of ways and means, in which position his fluency, skill at retort, and acrimonious wit made him the acknowledged leader in debate of the administration party. In 1806, however, he quarrelled with the administration and assailed President Jefferson and his supporters with great virulence. He also attacked Madison's administration, and opposed vigorously the declaration of war against Great Britain in 1812. His opposition caused his defeat at the next election, and he retired from the house, of which he had been a member for 12 years. He was, however, reelected in 1814 and again in 1818, having declined to be a candidate in 1816. In the congress of 1819–'20 he vehemently opposed the Missouri compromise, stigmatizing the northern members by whose coöperation it was carried as "doughfaces," an epithet at once adopted into the political vocabulary of the United States, and still in use. In 1822, and again in 1824, he visited England, where his eccentricities and strange figure and costume attracted considerable attention. From 1825 to 1827 he was a senator of the United States. He supported Mr. Crawford for president in 1824, and Gen. Jackson in 1828. In 1829 he was a member of the convention to revise the constitution of Virginia, and in the following year was appointed minister to Russia, an office which he accepted on condition that he might spend the winter in the south of Europe, as his health, which for some years had been seriously impaired, was now exceedingly feeble. Soon after his reception by the emperor, he departed abruptly for England, where he remained for nearly a year, and returned home without revisiting Russia. His district again elected him to congress, but he was too ill to take his seat. Exhausted with consumption, he died in a hotel at Philadelphia, whither he had gone on his way to take passage again across the ocean. —During his life Mr. Randolph's speeches were more fully reported and more generally read than those of any other member of congress. In the house he was always listened to with intense interest, and the force of his eloquence was heightened by his personal appearance, which was singularly striking. He was tall and very slender and cadaverous, with long, skinny fingers, which he was in the habit of pointing and shaking expressively at those against whom he spoke. His voice was shrill and piping, but under perfect command and musical in its lower tones. His favorite weapons in debate were invective and sarcasm, and for many years his sharp and reckless wit made him a terror to his opponents in the house. "For more than 30 years," says Mr. Benton, "he was the political meteor of congress, blazing with undiminished splendor during the whole time, and often appearing as the 'planetary plague' which shed, not war and pestilence on nations, but agony and fear on members. Wit and genius all allowed him; sagacity was a quality of his mind visible to all observers, and which gave him an intuitive insight into the effect of measures. He was long the chairman of the committee of ways and means—a place always of labor and responsibility, and of more then than now when the elements of revenue were less abundant; and no man could have been placed in that situation during Mr. Jefferson's time whose known sagacity was not a pledge for the safety of his lead in the most sudden and critical circumstances. He was one of those whom that eminent statesman habitually consulted during the period of their friendship, and to whom he carefully communicated his plans before they were given to the public." Randolph was one of the largest slaveholders of Virginia, and at the time of his death possessed 318 slaves, whom by his will he manumitted, at the same time bequeathing funds for their settlement and maintenance in a free state. In 1803, as chairman of the committee upon a memorial from Indiana asking for permission to introduce slaves into that territory in spite of the prohibition of the ordinance of 1787, he reported adversely to the petition on the ground that the ordinance was "wisely calculated to promote the happiness and prosperity of the north-western country." —See "Life of John Randolph," by Hugh A. Garland (2 vols. 8vo., New York, 1850).

RANDOLPH, Peyton, an American patriot, president of the first congress, born in Virginia in 1723, died in Philadelphia, Oct. 22, 1775. He was the second son of Sir John Randolph, and after having been graduated at the college of William and Mary, he was sent, like young men of the aristocracy, to complete education in England, and studied law at the Temple. In 1748 he was appointed king's attorney for the colony, and the same year chosen a member of the house of burgesses for the city of Williamsburg. During that session he was made chairman of a committee authorized to prepare a general revisal of the laws of the colony, and from this time continued one of the most active and influential members of the assembly. In 1752 Lieut. Gov. Dinwiddie came into conflict with the Virginia house of burgesses by imposing a fee equivalent to [illegible] for every seal annexed to a grant of land. Randolph was sent by that body as their agent to England to procure redress for their grievances, but was unsuccessful in his mission. In 1755, after the defeat of Braddock, he and [illegible] other gentlemen formed a regiment for the purpose of joining at the frontier the colonial force under Washington; but as the enemy retreated to Fort Duquesne, no engagement took place. In 1764 the Virginia house of burgesses voted an address to the king against the passage of the stamp act, and Randolph drew it up. When in 1765 that act became a law, Patrick Henry moved on May 30 his celebrated 5 resolutions, which Randolph strongly opposed, not however on any question of our rights, "but on the ground," says Jefferson, "that the same sentiments had been at the preceding session expressed in a more conciliatory form, to which the answers were not yet received." (See Henry, Patrick.) When in the same year congress met at New York, and Virginia was prevented by her governor from sending deputies, the assembly of that state forwarded to England petitions of a character similar to those adopted by the congress. The address to the king was written by Randolph. On April 1[illegible] 1766, on the death of Speaker Robinson, Randolph was made speaker of the house of burgesses, resigning about the same time his office of attorney-general. In the measures of opposition to the English government he now took a conspicuous part. In March, 1773, on the reception of copies of an address and resolutions from the Massachusetts assembly, Randolph was one of the most prominent in urging instant and bold action. A committee of vigilance was appointed, of which he was one, to obtain the most accurate and clear intelligence of all acts of parliament affecting the rights of the colonies; and it was also authorized to open a correspondence with the other colonies. In the convention which met in Aug. 1774 at Williamsburg, Randolph presided, and was one of the delegates elected to the continental congress appointed to meet in Philadelphia in the following September. On the assembling of that body he was unanimously elected its president, but in consequence of ill health held that position only 5 or 6 weeks. In 1775 he presided over the second convention of Virinia, which assembled at Richmond on March 0, and was elected again as a delegate to congress, with the substitution of Jefferson in his place in case of his non-attendance. That body met at Philadelphia on May 10, 1775, and Randolph was reëlected president; but finding it necessary to return to Virginia to resume the duties of speaker of the house of burgesses, he was succeeded in his office by John Hancock. He died suddenly of apoplexy. He was a man of excellent judgment, though without genius, of imposing presence, incorruptible integrity, and extremely intolerant to religious dissenters. He was buried in the chapel of William and Mary.

RANGOON, the commercial capital of Pegu, situated on the left bank of the E. branch of the Irrawaddy, about 25 m. from the sea, in lat. 16° 47′ N., long. 96° 18′ E.; pop. 20,000. About 2 m. below the town the river divides into two arms, both of which are navigable, but the W. branch, called the Rangoon river, is generally preferred. The town extends about a mile along the river, and the streets are narrow but clean and well paved. The houses are raised on posts, but there are a few built of brick, chiefly belonging to Europeans, and since its occupation by the British the place has been fortified. There are some curious Buddhist pagodas and monuments. Rangoon was built in 1755, when the Burmese conquered Pegu. It is well suited for ship building, as the tide rises from 16 to 24 feet, and a large quantity of teak timber is floated down the Irrawaddy. In Jan. 1852, Rangoon was taken by the British. In 1853 it suffered from a severe fire which burned a great part of the town; and again in 1856 it was almost destroyed by fire.

RANKE, Leopold, a German historian, born in Wiehe, near Naumburg, Dec. 21, 1795. In 1818 he became principal teacher of the gymnasium of Frankfort-on-the-Oder, but occupied himself chiefly with historical studies. In 1824 appeared at Berlin the 1st volume of his *Geschichte der Romanische und Germanische Völker* von 1494–1535. He was in 1825 made professor of history in Berlin, and soon after was sent by the Prussian government to Vienna, Venice, Rome, and Florence, to search for historical materials in the archives of those cities. The results of his labors were first made manifest in a work entitled *Fürsten und Völker von Süd-europa im 16ten und 17ten Jahrhundert* (1827). In 1829 he published *Die Serbische Revolution*, in 1831 *Ueber die Verschwörung zu Venedig*, and in 1834 *Vorlesungen zur Geschichte der Italienische Poesie*. His work entitled *Die Römischen Päpste, ihre Kirche und ihr Staat* ("The Popes of Rome, their Church and State," 3 vols., Berlin, 1834–'6) has been three times translated into English: by Mrs. Austin in 1840; by Scott, with an introductory essay by Merle D'Aubigné, in 1846; and by E. Foster in 1848; in 1832 he began the *Historisch-politische Zeitschrift* (vol. i., Hamburg, 1832; vol. ii., Berlin, 1833–'6), which being decried as illiberal was discontinued in 1836. His next work was *Deutsche Geschichte im Zeitalter der Reformation* ("History of Germany in the Time of the Reformation," 6 vols., Berlin, 1839–'47), in which he gave an account of the rise of Protestantism. This work, which has also been translated into English by Mrs. Austin, is considered his best. It was followed by *Neun Bücher Preussischer Geschichten* (3 vols., Berlin, 1847–'8), for aid in writing which the Prussian archives were for the first time opened. This work has been translated by Sir A. and Lady Duff Gordon, under the title of "Memoirs of the House of Brandenburg, and History of Prussia during the 17th and 18th Centuries." Turning his attention to French history, he wrote *Französische Geschichte vornehmlich im 16ten und 17ten Jahrhundert* (3 vols., Stuttgart, 1852–'5), which contains an account of Protestant struggles in that country. Beside these he has written *Jahrbücher des Deutschen Reichs unter dem Sächsischen Hause* (3 vols., Berlin, 1837–'40), and several other historical works.

RANKIN, a central co. of Miss., bordered W. and N. W. by the Pearl river and drained by its branches; area, about 800 sq. m.; pop. in 1860, 13,637, of whom 7,105 were slaves. Its surface is covered with pine forests, and its soil is generally fertile. The productions in 1850 were 217,673 bushels of Indian corn, 68,206 of sweet potatoes, 66,105 lbs. of rice, and 2,675 bales of cotton. There were 15 churches, and 340 pupils attending public schools. It is intersected by the southern Mississippi railroad, which passes through the capital, Brandon.

RANTOUL, Robert, jr., an American statesman, born in Beverly, Mass., May 13, 1805, died in Washington, D. C., Aug. 7, 1852. His father, who survived him for several years, was long a member of the state legislature. The son was educated at Phillips academy, Andover, and at Harvard college, where he was graduated in 1826. He studied law with John Pickering in Salem, was admitted to the Essex bar in 1827, and for several years practised in Gloucester, from which town he was in 1834 and in 3 succeeding years elected a member of the legislature, where he distinguished himself as a reformer and as an advocate of the rights and interests of the common people. He exerted himself for the abolition of capital punishment, and made a report to the legislature on that subject, which is still one of the standard authorities of the opponents of the practice. In 1837 he was appointed a member of the Massachusetts board of education, and gave much time and attention to the advancement of the system of public instruction. In 1843 the president appointed him collector of the port of Boston, and in 1845 he was made U. S. district attorney. In 1851 he was elected U. S. senator to succeed Daniel Webster for the short remainder of his term; and in the same year, having taken his position prominently among the opponents of the extension of slavery, the freesoilers of his district united with the democrats in electing him to the U. S. house of representatives, of which he was a member at the time of his sudden death. A volume of his speeches and writings, with a memoir, was published in Boston in 1854.

RANUNCULUS (Lat., a little frog), the botanical name of certain herbaceous plants with more or less divided leaves and showy flowers, which grow in places frequented by the frog. The ranunculi are either perennial or annual, with mostly radical leaves, and flowers either solitary or somewhat corymbed, the prevalent color yellow, though sometimes white; the calyx has 5 sepals, and the corolla 5 petals, with a scale or pit inside each petal at base; the stamens are numerous; the fruit (*achenes*) many, compressed, ovate, pointed, and disposed in roundish or cylindrical heads. They bear the names of spearworts, crowfoots, buttercups, kingcups, and the like, in reference to the form of the foliage or the bright hue and shape of the blossoms. The ranunculus is the type of the natural order *ranunculaceæ*, which embraces herbs, woody vines, and subshrubby plants, all conspicuous for the beauty of their flowers and the acridity of their juices, found growing for the most part in northern frigid and temperate regions. The number of species of ranunculus, according to Persoon's *Synopsis* in 1807, is 85; but in the *Hortus Britannicus*, published in 1830, there are 95 enumerated; the number found in the United States alone, according to Torrey and Gray's "Flora of North America," is 44, including a few that are considered doubtful; several are regarded as adventitious from Europe. A few are remarkable for beauty, such as the alpine crowfoot (*R. alpestris*, Linn.), a little plant 3 to 8 inches high, with thickened fibrous roots, smooth leaves with 3 to 5 lobes, flower stems either solitary or several; flowers 1 or 2 at the summit, white; petals recurved, heart-shaped. It is found on the highest summits of the Austrian Alps, and on the Jura, blooming in June and July. The fair maids of France (*R. aconitifolius*, Linn.) is of a different style, having a stem 2 or 3 feet high, palmipartite, toothed, and incised leaves, and white blossoms of 5 or 6 petals and pubescent sepals. There is a multiplex-petalled variety much cultivated in Europe, under the above fanciful name, as a choice border perennial; and another variety is known in the wild state, in which the leaves differ permanently in their shape. Several aquatic species with finely cut leaves have very pretty white flowers, which rise just above the surface of the water. But perhaps the most remarkable of all the crowfoots is the common garden ranunculus (*R. Asiaticus*, Willd.), from the fact that it is the original type and parent of innumerable superb forms with double and multiplex-petalled flowers of every shade and hue. This species, indigenous to the Levant, is a low plant with ternate or biternate radical leaves, an erect, simple or branched flower stalk, variously colored, 5-petalled flowers, and a cylindrical spiked fruit. Maddock, a celebrated florist, enumerates 800 sorts with proper names and ranged in groups according to their several colors, as purple, gray, crimson, red, rosy, orange, yellow, white. These have some characteristic mark by which they are known, and were produced by sowing the seeds of the finest semi-double varieties. Whatever is the parent plant, none of its offspring, however numerous, resemble it. Thus an endless variety can be expected, and out of a large number only the very best are selected. To increase these, the roots are carefully divided, each division flowering in the second year. There are two distinct sorts known as the Turkey and the Persian, both of which require a rich loamy soil that is well manured. They are planted in the autumn, by placing their small, forked, tuberous roots 6 or 8 inches apart in beds of soil free from stones, it being found that stronger blossoming is thereby secured.—Three species of ranunculus, known as buttercups or kingcups, adventitious from Europe, are common weeds in our pastures, fields, and meadows. They are conspicuous for their large, cup-shaped, golden-hued blossoms, and are attractive plants in the garden when in their double-flowered form, requiring only occasional taking up of the roots and transplanting. They are the bulbous crowfoot (*R. bulbosus*, Linn.), with a solid fleshy root, acrimonious and almost caustic; the tall crowfoot (*R. acris*, Linn.), with a fleshy, fibrous root; and the creeping crowfoot (*R. repens*, Linn.), with a prostrate stem and numerous runners. A widely distributed species, ranging from extreme arctic America to the Rocky mountains, and appearing in other parts of the United States, is Pursh's crowfoot (*R. Purshii*, Richardson), and the *R. Sabinii* of R. Brown is one of the few plants that constitute the scanty flora of Melville's island. The early crowfoot (*R. fascicularis*, Muhlenberg) is one of the first harbingers of a New England spring; its flowers are small and yellow. The small-flowered crowfoot (*R. abortivus*, Linn.) blossoms early in shady places, and ventures into the garden as a weed. A curious variety known as the *R. a.* var. *micranthus* is by no means common. The sea crowfoot (*R. cymbalaria*, Pursh) prefers the seaside or the vicinity of salt springs; it has been found from the Arctic sea, in lat. 68°, and met with on saline spots across the continent to the Pacific ocean.—The order *ranunculaceæ* comprises many other beautiful flowering plants, such as the *anemone*, *clematis*, *adonis*, *caltha*, *trollius*, *delphinium*, and *aquilegia;* and many useful in medicine, such as *helleborus*, *coptis*, *aconitum*, and *podophyllum*. In geographical distribution, the largest proportion is found in Europe, which contains more than ⅓ of the whole; very few are found in Africa, and North America possesses about ⅐.

RANZ DES VACHES, the name applied to certain simple melodies played by the mountain shepherds of Switzerland upon the Alpine horn.

nd which are identified with the scenes and ursuits incidental to pastoral life. The term, hich is rendered in German by *Kuhreihen*, means literally cow rows, and is so called from he fact that the cattle, when answering the musical call of the shepherd, move toward him n a row, preceded by those wearing bells. The character of these melodies, which are scarcely such in fact, as they are not governed y the ordinary rules of music, varies in different parts of Switzerland. They are in general without words. A collection of the various *Ranz des Vaches* and other Swiss airs was published in 1818 under the title of *Sammlung von Schweizer Kuhreihen und Volksliedern* (Bern). They are also incorporated in the *Allgemeines Schweizer Liederbuch*, published in 1851.

RANZANI, Camillo, an Italian naturalist, born in Bologna, June 22, 1775, died there, April 23, 1841. At the age of 22 he became professor of philosophy in the university of Fano, where he received holy orders, and taught until 1798. Political disturbances compelling him then to return to Bologna, he was appointed keeper of the botanical garden of that city, and in 1803 professor of natural history in the university, of which he became rector in 1824. In 1836 he introduced a course of lectures on geology, a study which had received little favor in Italian schools. His principal work is his *Elementi di zoologia*, of which 19 volumes were published, and which his death left incomplete.

RAOUL-ROCHETTE, Désiré, a French archæologist, born at St. Amand, department of Cher, March 9, 1790, died July 5, 1854. He was educated at the college of Bourges, repaired to Paris at the age of 21, and in 1813 obtained a prize at the institute for a work upon the "History of the Greek Colonies." In 1815 he succeeded M. Guizot in the professorship of history at the faculty of letters. He became a member of the academy of inscriptions, and one of the contributors to the *Journal des savants* in 1816; succeeded Millin as keeper of the cabinet of medals in the royal library in 1818; held the office of royal censor of newspapers in 1820; and was assistant of Quatremère de Quincy in the chair of archæology in 1824, and succeeded him in 1826. In 1828 he was one of the scientific commission sent by the French government to the Morea. He was admitted in 1838 to the academy of fine arts, of which he became perpetual secretary in the following year. The government of 1848 deprived him of his office as keeper of the cabinet of medals. His works on archæological subjects are extremely numerous.

RAPE (law French, *rapt*; law Latin, *raptus*), the violation or carnal knowledge of a woman, forcibly and against her will. Early English statutes, which have perhaps in the United States the force of common law, extend this to the case of a woman child under the age of 10 years carnally known either with or against her will. Every civilized nation, ancient and modern, has declared by its criminal code its abhorrence of this offence, and affixed to its commission the severest punishments. By the Mosaic law, to ravish a damsel who was betrothed to another was a crime punishable with death; and in case of one not betrothed, the offender was compelled to take the damsel to wife and pay her father a fine of 50 shekels. By the civil law rape was punishable with death and confiscation of goods. Unlike our law, however, the civilians made no distinction between rape as defined by us, of which force is the characteristic element, and seduction without force, of which the criminal law of England and of the United States takes no cognizance; and by the civil law the unlawful carnal knowledge of a woman with her consent was subject to the same severity of punishment as if obtained forcibly and against her will. This, we are told, was because the Roman law entertained so high an opinion of the virtue and chastity of woman, that it would not presume her to be capable of a violation of those qualities, unless induced thereto by the evil arts and solicitations of man; and in order to secure her the more effectually from the danger of these, it made such a violation of chastity, however consummated, equally a crime in him, and visited its penalties upon him alone. By the Saxons, rape was also esteemed a felony and punished with death, though the woman ravished (if single) might redeem the offender from execution if she were willing to accept him as her husband, and he were willing to be so redeemed. But William the Conqueror, probably deeming the punishment of death too severe, altered it to castration and loss of the eyes. In the reign of Edward I. the law was still further modified, and rape was declared to be, and was punished as, a misdemeanor only; but the consequences of this amelioration proving disastrous and inducing a fearful increase of the crime, 10 years afterward, during the same reign, it was restored to the rank of felony and punished as before with death; but by 9 George IV. and 4 and 5 Victoria it was made a non-capital felony, punishable by transportation for life, instead of death, as formerly. In the United States, although by statute the punishment varies somewhat in different states, it is by all treated as felony and punished either with death or imprisonment for life.—It was for a long time an unsettled question what was requisite to constitute this offence, and proof of the full accomplishment of the act was once considered indispensable in order to secure a conviction. As far as the wrong and outrage to the individual is concerned, the crime is perhaps equally entire where the offence is imperfectly committed. But the physical completion of the offence is not now necessary, in law, to complete the guilt of the offender; for it is not the degree of gratification to the lust of the ravisher which gauges the degree of criminality, but the injury done to the person and feelings of the victim, and the dastardly violation of that mod-

This, the first work executed by Raphael in Rome, is also the last of his large compositions which contains traces of his early religious, Peruginesque manner. The influence of the antique, which he here first felt in its fulness, the proximity of Michel Angelo, who was then painting his sublime frescoes in the Sistine chapel, and the importance and grandeur of the subjects upon which he was engaged, gave a new impulse to his genius, and he reached almost at a single step the limit of his style. His next work in point of date, "Poetry" or "Parnassus," representing an assembly of Greek, Roman, and Italian poets on Mount Parnassus, with Apollo and the Muses in the centre, marks perhaps the transition period; but in "Philosophy" or the "School of Athens," which followed, the Roman style is matured. The composition represents a grand hall or portico, in which are characteristically grouped the great philosophers and sages of antiquity. The remaining fresco in this *stanza*, "Jurisprudence," owing to the peculiar construction of the wall, is divided into 3 compositions, Gregory delivering the ecclesiastical law and Justinian promulgating his code of civil law, above which are female personifications of prudence, fortitude, and temperance. These frescoes were finished in 1511, and appear to have been immediately succeeded by those in the *stanza* of Heliodorus, so called from the story of the expulsion of Heliodorus from the temple, as related in the 2d book of Maccabees, which is painted on one of its walls. In this composition the group of Heliodorus and the pursuing angels is especially noticeable for its supernatural power. The "Mass at Bolsena," "Attila terrified by a Celestial Vision," and "St. Peter delivered from Prison" occupy the remaining walls of this *stanza;* and on the ceiling are representations of the promises of God to the four patriarchs, Abraham, Isaac, Jacob, and Moses. Julius died during the progress of the work, but his successor, Leo X., directed its completion, as also that of the other works in the Vatican on which Raphael was engaged, beside intrusting him with new ones. Before this time, however, commissions multiplied so greatly upon the painter's hands, that he was obliged to commit to the best of the numerous scholars who now resorted to him from all parts of Italy the execution of portions of the frescoes in the remaining *stanze* from his cartoons and designs. In this manner was painted the *stanza dell' incendio*, which takes its name from the principal subject illustrated, the "Fire in the Borgo," and in which are represented the prominent events in the lives of Popes Leo III. and IV. The frescoes in the *sala di Costantino*, the last of the series, were executed after his death under the direction of Giulio Romano, his most eminent pupil. They all suffered from neglect after the removal of the popes to the Quirinal palace, and were cleaned and in some instances restored by Carlo Maratti in the 18th century. While engaged on these works Raphael executed in fresco for Agostino Chigi, a banker of Rome, the 4 grand figures of the Sibyls in the Chigi chapel of Sta. Maria della Pace, and the well known "Triumph of Galatea," beside many Madonnas and other easel pictures. His fortune kept pace with his celebrity, and he lived in princely magnificence, honored by the chief statesmen and authors of the day, and admired and beloved by all contemporary artists, excepting Michel Angelo, whose haughty spirit ill endured the fame of his young rival. During the progress of the later works in the *stanze* Leo X. employed Raphael on two other important undertakings, the decoration of the *loggie*, or open galleries running round 3 sides of the court of St. Damasus (the older portion of the Vatican), and the designs for the tapestries of the Sistine chapel. For the *loggie* he furnished a celebrated series of designs from the Old Testament, known as "Raphael's Bible," and which were executed in 13 small cupolas on the gallery on the 2d story by Giulio Romano, Francesco Penni, Pellegrino da Modena, Perino del Vaga, and others of his pupils. A variety of beautiful arabesque ornaments and stuccoes in the same gallery were executed from his designs by Giovanni da Udine. The cartoons for tapestries, prepared probably between 1513 and 1516, represent the highest efforts of Raphael's genius in historical composition. They are from 14 to 18 feet in length by 12 in height, and are colored in distemper. The subjects illustrated are the "Death of Ananias," "Elymas the Sorcerer struck with Blindness," "The Healing of the Lame Man at the Beautiful Gate of the Temple," "The Miraculous Draught of Fishes," "Paul and Barnabas at Lystra," "Paul preaching at Athens," and "The Charge to Peter;" these cartoons, at the suggestion of Rubens, were purchased by Charles I. of England, and are now deposited in Hampton Court palace. The remaining cartoons of the series, representing the "Stoning of Stephen," the "Conversion of St. Paul," and "Paul in the Prison of Philippi," are lost. The original tapestries, for which the pope paid the manufacturers in Arras 50,000 gold ducats, after various mutations of fortune, are now in the Vatican, but are so injured and faded that the general effect of the coloring is destroyed. Raphael also furnished the designs, but not the cartoons, for a second series of 10 tapestries, which are also in the Vatican. Amid these great undertakings he did not neglect the subjects which had first inspired his pencil, and the numerous Madonnas and holy families produced during his residence in Rome include some of the most characteristic and admirable of his works. Distinguished among them is the wonderful *Madonna di San Sisto* (painted between 1517 and 1520) in the Dresden gallery, representing the Virgin standing in a majestic attitude with the child in her arms. It is said to have been painted at once on the canvas, without any preliminary study, and has been engraved in a style not unworthy of the original by Friedrich Müller. Other celebrated Madonnas of this period are the Aldobrandini Madonna, in the possession of Lord Garvagh, that known as the Bridgewater, the *Vierge au diadème* in the Louvre, the lovely *Madonna della sedia* or *seggiola* in the Pitti palace, the *Madonna di Foligno* in the Vatican, that called the "Pearl" at Madrid, and the *Madonna del pesce* in the Escurial, the two last mentioned being altar-pieces with saints assembled around the Virgin. Of several of these duplicates exist, and all of them have been repeatedly engraved. Among his remaining easel pictures are the St. Cecilia, now in Bologna; the "Archangel Michael overcoming the Devil," in the Louvre; "Christ bearing the Cross," known as *Lo spasimo di Sicilia*, in Madrid; and his last, and by many considered his grandest work, the "Transfiguration," in the Vatican, painted in competition with Sebastian del Piombo's "Raising of Lazarus," of which Michel Angelo is said to have furnished the design. Of his portraits, of which he executed upward of 50, the most famous are those of Julius II. and Leo X., the originals of both of which are in Florence, Cardinals Bibbiena, Bembo, de' Medici, and de' Rossi, Joanna of Aragon, and the "Fornarina," which was long supposed to represent one of his mistresses, but which Passavant considers to be the portrait of a celebrated improvisatrice named Beatrice Pio. The last named picture is in the Barberini palace in Rome. To this list of works must be added the fresco of "Cupid and Psyche" in the villa Farnesina, and numerous drawings in chalk, from which Marc' Antonio Raimondi, who engraved many of Raphael's best works, executed several of his finest plates. If in addition we mention that he directed the construction of St. Peter's from his own plans subsequent to the death of Bramante in 1514, beside executing several other architectural works; that in the latter part of his life he had commenced important researches into the architectural remains of Roman antiquity; and that he executed at least one statue in marble, beside designing others, we have the record of a life which, considering its brevity, is without a parallel in the history of art. He died of a fever caught in superintending some subterranean excavations, and was buried in the Pantheon, near the remains of Maria di Bibbiena, niece of the cardinal of that name, to whom he had been betrothed. Through some doubt as to the place of his sepulchre, his remains were exhumed in Sept. 1833, and on Oct. 18 reinterred with great ceremony. Of his private character Mrs. Jameson says: "There was a vulgar idea at one time prevalent that Raphael was a man of vicious and depraved habits, and even died a victim to his excesses; this slander has been silenced for ever by indisputable evidence to the contrary, and we may now reflect with pleasure that nothing rests on surer evidence than the admirable qualities of Raphael; that no earthly renown was ever so unsullied by reproach, so justified by merit, so confirmed by concurrent opinion, so established by time." His life has been written by Quatremère de Quincy and Passavant, the work of the latter being the latest and fullest; and more briefly by Mrs. Jameson in her "Memoirs of the early Italian Painters." See also Kugler's "Handbook of Italian Schools."

RAPHALL, Morris Jacob, Ph.D., a Jewish rabbi and author, born in Stockholm, Sweden, in Sept. 1798. Being designed by his parents for the ministry, he was sent at an early age to the Jewish college at Copenhagen, where, when but 12 years old, he received the degree of *chabir* or *socius*, which entitled him to the designation of rabbi. In 1812 he went to England, and there acquired so complete a mastery of English as to speak it with the fluency of a native. In 1818-'20 he made a tour of the continent, and in 1821 entered the university of Giessen, where he remained nearly 4 years. In 1825 he returned to England, where he married and took up his residence, distinguishing himself as a lecturer on Hebrew biblical poetry. In 1834 he commenced a weekly periodical, "The Hebrew Review, or Magazine of Rabbinical Literature," the first Jewish periodical ever published in Great Britain; but in 1836 impaired health compelled him to relinquish it. Between 1834 and 1837 he translated into English some writings of Maimonides, the *Sepher Ikkarim* or "Book of Principles" of the rabbi Joseph Albo, and the *Yain Lebanon*, a work on ethics, of Rabbi Naphtali Hirtz Wessely. In 1839 he published "Festivals of the Lord," a series of essays on Jewish festivals. The persecution of the Jews at Damascus in 1840 brought him into intimate relations with the chief rabbi of England, Dr. S. Hirschel, for whom he acted as secretary, and at whose instance he drew up an expurgatory declaration, in Hebrew, English, French, and German. During that year he again visited Germany, and soon after his return published, jointly with the Rev. D. A. De Sola of London, a translation of 18 treatises of the *Mishna*. Soon afterward he commenced, in connection with Messrs. De Sola and Lindenthal, a translation of the Hebrew Scriptures, with copious notes, of which only Genesis has yet been published. In 1841 he was appointed rabbi preacher to the synagogue at Birmingham, where he devoted his energies to the founding of a Hebrew national school, the first created by the provincial Jews of England. He was also engaged in several controversies in regard to Judaism, and published 3 or 4 polemical works on the subject. He was a frequent contributor to periodicals, and lectured with success on biblical poetry, the post-biblical history of the Jews, and on geography and statistics. He also advocated publicly the removal of the civil disabilities of the Jews. In 1849 he determined to remove to the United States, and on his departure the mayor and principal inhabitants of the city of Birmingham, of all denominations, united in an address thanking him for his efforts in the cause of public education, and in behalf of the public institutions of the city. The address was accompanied by a purse of 100 sovereigns. On his arrival in New York, he accepted a call from the first Anglo-German Hebrew congregation of the city, known as the "Great Synagogue," to serve them as rabbi preacher. In 1852 he published "Devotional Exercises for the Daughters of Israel;" in 1856 his lectures on the "Post-Biblical History of the Jews," carefully revised, in 2 vols.; in 1859 a small pamphlet entitled "The Path to Immortality;" and in 1861 a discourse under the title, "The Bible View of Slavery."

RAPIDES, a W. parish of La., separated from Texas on the W. by the Sabine river, bounded N. E. by Little river, and intersected by the Red and Calcasieu rivers; area, about 2,000 sq. m.; pop. in 1860, 25,360, of whom 15,358 were slaves. The surface is nearly level and the soil generally fertile. The productions in 1855 were 610,645 bushels of Indian corn, 15,084 hhds. of sugar, 49,546 bbls. of molasses, and 22,285 bales of cotton. Capital, Alexandria.

RAPIN-THOYRAS, Paul de, a French historian, born in Castres in 1661, died in Wesel, May 16, 1725. He was of a Protestant family which came originally from Savoy, and became an advocate, but subsequently turned his attention to the profession of arms and to literary studies. Obliged to leave France by the revocation of the edict of Nantes, he first went to England, where he arrived in 1686, and from that country passed over to Holland, and there joined a company of French cadets, and followed the prince of Orange (William III.) to England. He was present at the battle of the Boyne, and was severely wounded in the siege of Limerick, and in consequence forced to quit the army. He afterward became tutor of the young earl of Portland, and in 1707 settled in Wesel, on the Rhine, where he composed his works. Of these the most important is his *Histoire d'Angleterre* (9 vols. 4to., the Hague, 1724), in which the narration of events is carried down to the death of Charles I. It was translated by N. Tindal, with a continuation to the death of George I., and often printed (2 vols. fol., 1722; 5 vols. fol., 1743; 21 vols. 8vo., 1757). The work is generally marked by accuracy of statement and clearness of expression, and forms a complete body of English history which had no competitor till the work of Hume; as a careful and trustworthy compilation it is scarcely yet superseded.

RAPOPORT, Solomon Jehudah, a Jewish antiquary and rabbi, born in Lemberg, Austrian Galicia, in June, 1790. He first attracted attention among his coreligionists by notes to a Talmudical work of his father-in-law, Rabbi Löw Neller, and subsequently rose to the highest rank among the Hebrew writers of the age by critico-biographical and other contributions to the periodicals *Bikkure haittim* (Vienna, 1820–'31) and *Kerem hemed* (Vienna and Prague, 1833–'45), and numerous minor dissertations in Hebrew and German inserted in various other publications. He translated into Hebrew verse Racine's "Esther," entitled *Sheerith Jehudah* (Vienna, 1827). His principal work is *Erech millin* (1st vol., Prague, 1852), which is to form part of a comprehensive historico-critical dictionary of rabbinical knowledge in two divisions. Having officiated for some time as rabbi at Tarnopol, he was elected in 1840 to fill a similar office at Prague, a position which he still holds. His 70th birthday, in 1860, was the occasion of salutatory addresses from numerous Jewish congregations of the European continent, England, and America.

RAPP, Georg, founder of the sect of the Harmonists, born in Würtemberg in 1770, died at Economy, Penn., Aug. 7, 1847. In his younger days he believed that he had experienced a divine call, and that he was charged with the restoration of the Christian religion to its original purity. He did not long confine himself to spiritual matters, but formed the plan of a community organized on the model of the primitive church with goods in common. As in the promotion of this object he was hindered by the state, he removed in 1803 with his followers to America. (See Harmonists.)

RAPP, Jean, a French general, born in Colmar, April 29, 1772, died in the grand duchy of Baden, Nov. 18, 1821. He entered a cavalry regiment in the French army as a private in 1788, distinguished himself during the wars of the revolution, became an aide-de-camp of Desaix during the campaigns in Italy, and went with that general to Egypt. After the battle of Marengo he was promoted by Napoleon, and attached to his staff. When Napoleon became emperor Rapp was raised to the rank of brigadier-general. At the battle of Austerlitz he decided the victory by precipitating his force upon the Russian imperial guard, driving all before him, and taking Prince Repnin prisoner; for this he was made general of division. He distinguished himself highly in the succeeding campaigns, especially at the battle of Golymin, where he was wounded for the 9th time. To enable him to recruit his health he was intrusted with the government of Thorn, and subsequently with that of Dantzic. He was in the campaign against Russia, receiving at the Moskva his 22d wound; and after the disastrous result of that invasion he threw himself into Dantzic, where he was blockaded by the Prussians and Russians. He held out 12 months, but was finally compelled to surrender, and was carried to Russia as prisoner of war. Returning to France upon the first restoration, he was intrusted by Louis XVIII. with the command of the first army corps, charged with the duty of resisting the march of Napoleon. But, following the example of others, he soon went over to his old leader, and was appointed by being commander of the 5th division, member of the chamber of peers, and commander-in-chief of the army of the Rhine. There, pressed by an Austrian army far superior to his in numbers, he retired to Strasbourg, and after the second restoration betook himself to Switzerland. In 1818 he returned to France, and was received with favor and reinstated in the army. When the news of Napoleon's death reached France, Rapp burst into tears in the presence of the whole court. He wrote a description of the siege of Dantzic, and also left a volume of "Memoirs," published in 1823.

RAPPAHANNOCK, a river in the E. part of Virginia, formed by the confluence of the North fork and other small streams, which rise in the Blue ridge and unite on the N. E. border of Culpepper co. At the S. E. extremity of that county it receives the waters of the Rapidan, its largest tributary; thence flowing about 40 m. in a devious course, it reaches tide water at Fredericksburg, where by a fall it supplies valuable power; thence it becomes navigable, and enters Chesapeake bay by an estuary about 70 m. long. The whole length in a straight line from its sources to Chesapeake bay is about 140 m., but with its numerous and intricate windings its real length must be nearly twice as much. Its general course is S. E.

RAPPAHANNOCK, a N. E. co. of Va., bordered N. E. by the North fork of the Rappahannock, and drained by others of its head waters; area, about 250 sq. m.; pop. in 1860, 8,850, of whom 3,520 were slaves. It is bordered on the N. W. by the Blue ridge, and has a generally fertile soil. The productions in 1850 were 157,699 bushels of wheat, 218,216 of Indian corn, 3,273 tons of hay, 2,785 lbs. of tobacco, and 24,946 of wool. There were 15 grist mills, 11 churches, and 137 pupils attending public schools. Value of real estate in 1856, $2,029,432, showing an increase of 36 per cent. since 1850. Capital, Washington.

RARATONGA, or RAROTONGA, an island of the S. Pacific ocean, Cook's group; lat. (of centre) 21° 15' S., long. 160° 7' W.; pop. estimated at 4,000. It is about 30 m. in circumference, is surrounded by a reef, and has no anchorage for ships. It was first seen from the ship Seringapatam in 1814; but Mr. Williams, the missionary, also claims the discovery of it in 1823. The inhabitants have been converted to Christianity, and have made considerable progress in civilization.

RAREY, JOHN S. See HORSE, vol. ix. p. 266.

RARITAN, a river of New Jersey, formed by the confluence in Somerset co. of two branches, both having their sources in the mountains of Morris co.; the North branch flows nearly due S., and the South branch makes a curve S. W. through Hunterdon co., and then forms a circuit to the N. From the junction the course of the Raritan is nearly E. It passes by New Brunswick, whence it is navigable to Raritan bay, which it enters at Perth Amboy. The main stream is about 30 m. long.

RASK, RASMUS CHRISTIAN, a Danish philologist, born in Brendekilde, near Odense, on the island of Fünen, Nov. 22, 1787, died in Copenhagen, Nov. 14, 1832. He was graduated at the university of Copenhagen, was appointed an assistant in the university library in 1808, devoted himself to the study of northern history and literature, and in 1811 published in Danish his first work, an "Introduction to the Study of the Icelandic or Old Norse Language." With Nyerup in 1812 he made a journey to Sweden, and in 1813 went to Iceland, where he remained 2 years studying its history and literature. In 1816 he determined to undertake a journey to the East, and after remaining some time in Stockholm, and during the years 1818 and 1819 in Finland and St. Petersburg, occupied with the study of Finnish, Russian, Armenian, Persian, and Arabic, went to Persia and passed some time in Erivan, Teheran, Ispahan, Shiraz, and among the ruins of Persepolis. Thence he went to India and Ceylon, returned to Copenhagen in 1823, was soon after appointed professor of literary history in the university, and in 1829 was made professor of oriental languages and first librarian. According to Bunsen, Rask anticipated to a certain degree some of the greatest discoveries of Grimm, Bopp, and Burnouf. In his Icelandic, Anglo-Saxon, and Frisian grammars, he expounded the laws of those languages with the greatest possible completeness, first promulgated the law of the transposition of sounds, made the first comparative exhibition of German, Greek, Latin, and Lithuanian grammars, and originated the real knowledge of the Zend language.

RASKOLNIKS (Russ., schismatics, heretics), the collective name given to the religious sects of Russia which have originated by secession from the state church. They call themselves *starovertsi*, that is, adherents of the ancient faith. The origin of the various branches of Raskolniks is assigned to the middle of the 17th century, though some of them were strengthened by the scattered remains of former sects. The occasion for the formation of the Raskolniks was the corrected and altered edition of the Slavic translation of the Bible and the Slavic liturgical books, commenced in 1653 by order of the patriarch Nicon of Moscow, and ratified in 1654 by a synod at Moscow. Against this change of the official church rituals there arose a violent opposition, the leaders of which charged the state church with apostasy from the true faith, and proclaimed the necessity of leaving its communion. As they did not agree among themselves, a number of sects were founded at the same time. The Russian government has generally persecuted them all with the utmost rigor and cruelty, and their history therefore is involved in great obscurity. As they have had to keep themselves concealed, even their principles are very imperfectly known. In general they may be divided into two large classes, the "popish" sects, which have retained the office of priests (Russ. *pop*, priest), and, in general, the ecclesiastical organization of the state church; and the "anti-popish," which have no priests at all, but understand the general priesthood of the faithful in the widest and most literal sense of the word. The most important and best known among the numerous sects are the following: 1. The Duhobortzi, who first made their appearance under the reign of the empress Anna (1730-'40). They have neither churches nor ordained priests, reject oaths, condemn war, and resemble in many other points the society of Friends and the Mennonites. They were cruelly persecuted under Catharine II. and Paul, but obtained toleration under Alexander I. The Cossacks on the Don belong mostly to this sect, and a confession of faith, presented by them to the Russian government, has appeared in print. 2. The Pomorans have become especially celebrated for permitting suicide, for which they cite Mark viii. 35 *et seq.*, and which they generally accomplish by self-burning. The custom seems to have abated somewhat in modern times, but in 1860 an uncommonly large number of cases attracted the attention of the civilized world. They possess a confession of faith in 46 articles, drawn up at a synod in Poland in 1751. 3. The Philippons, called after their founder, a plain countryman named Philippos Pustosviet. A part of this sect, owing to the incessant persecution to which they were exposed, have emigrated from Russia. According to the census of 1858, about 1,200 of them were living in East Prussia, where the free exercise of their religion, ecclesiastical self-government, and exemption of the present generation from military service have been granted to them. 4. A special interest has been of late awakened in the Molokans, part of whom emigrated to Turkey, and there became acquainted with the Protestant missionaries from America, who represent them as agreeing in all essential points with the principles of Protestant Christianity. Their number is estimated at several millions.—About 10 years ago the chief sect of the "popish" Raskolniks prevailed on a Greek bishop of Austria to ordain one of their priests as a bishop, and thus obviated the main objection of the writers of the Russian church to their separate organization, that their connection with the apostolical church was interrupted. In order to relieve them from the necessity of living under the jurisdiction of bishops who, to avoid imprisonment, had to live in foreign countries on the Russian frontier, Alexander II. in 1859 issued an edict which makes it the duty of the bishops of the state church to consecrate the bishops and priests of the Raskolniks. As to the aggregate number of the Raskolniks, it is utterly impossible to obtain any trustworthy information, as every Russian census includes them in the membership of the state church. The statements of the Russian writers vary from 5,000,000 to 15,000,000, but the latter estimate is now generally believed to be nearer the truth, and the best accounts represent them as rapidly increasing. A comprehensive work on their history, with particular reference to the internal condition of the Russian church and civilization during the 17th and the first half of the 18th century, was published at St. Petersburg in 1859 by Shtchapoff.

RASPAIL, François Vincent, a French chemist and politician, born at Carpentras, department of Vaucluse, Jan. 29, 1794. He was educated at the seminary of Avignon with the design of entering the church, and in 1811, though but 17 years old, delivered there a course of lectures on philosophy, and in 1812 one on theology. Refusing to take orders, he went to Paris after the second restoration, and supported himself by private teaching. In 1824 he presented to the institute his first memoir, a treatise upon the classification of grasses, and in 1825 became attached to the *Bulletin des sciences* of Férussac. In 1729 he founded with M. Saigey the *Annales des sciences d'observation*. Becoming involved in a controversy with Cuvier and Geoffroy St. Hilaire, he issued against them in 1830 a work entitled *Coups de fouet scientifiques* ("A Scientific Horsewhipping"). Having from the first participated in the secret political movements of Paris, he took an active share in the revolution of July, 1830, when he was wounded; but he was opposed to the elevation of Louis Philippe, and refused to accept from him the cross of the legion of honor. He aided in the organization of the *amis du peuple* and other secret societies aiming at his overthrow, was the chief editor of the *Réformateur*, was many times prosecuted, and spent altogether 6 or 7 years in prison, where he wrote several of his scientific works, and his experience in which furnished the materials for the *Réforme pénitentiaire* (2 vols. 8vo., 1839). In 1840, on the celebrated trial of Mme. Lafarge for poisoning her husband, he offset the testimony of Orfila to the detection of arsenic in the intestines of the victim, by asserting that that proved nothing, since arsenic was diffused through all bodies, and could be found even in the wood of the judge's chair. This statement he developed at length in the *Mémoire à consulter* published by the defence, which gave rise to considerable controversy. Having adopted the theory that disease is most frequently occasioned by internal or external parasites, he fixed upon camphor as the best general agent for destroying them, which he prepared and sold at first in the form of cigarettes, afterward using it also in other modes and combining with it other remedies, according to circumstances. He published several works in exposition of his system, opened an office for gratuitous consultation, and met with great pecuniary success, though he was several times prosecuted and even imprisoned for illegal practice of medicine. In 1848 he headed the crowd which gathered at the Hôtel de Ville on the evening of Feb. 24, and proclaimed the reublic before the arrival of the provisional gov- rnment. Refusing any public office, he estab- ished the *Ami du peuple* daily newspaper. e was one of the leaders of the insurrection f May 15, and was arrested and confined at incennes till April, 1849, when he was tried nd condemned to 5 years' imprisonment at oullens. Notwithstanding his incarceration, e was, in Sept. 1849, elected by the depart- ent of the Seine a member of the national as- embly, and in December received 36,000 votes r the presidency. On his release in April, 854, he retired to Belgium, and has since pub- ished a periodical entitled *Revue complémen- aire des sciences appliquées.* He has written any valuable works on chemistry and kindred ientific subjects.

RASPBERRY (*rubus*, Linn.), a small edible uit of the natural order of *rosaceæ*. The owers consist of a 5-parted calyx without racteoles, 5 deciduous petals, and numerous tamens and styles. The fruit is a collection f carpels forming a hemispherical berry, hol- w beneath and falling off whole from the ry receptacle when ripe; the styles remain- g in a withered state give it a bristly appear- nce, from which the term rasp is applied to . The raspberry grows readily from seeds, d is widely distributed by the birds which ed upon it. It is liable to variation, especially nder cultivation. The species most generally ltivated is the *R. Idæus*, a native of Europe and f Mt. Ida in Crete, whence its specific name. rom this have originated a great many dis- inct and permanent varieties of much value, uch as the red and white Antwerp, the twice- earing, Barnet superb, red globe, Franconia, astolf, hornet, white transparent, prince of ales, Knevett's giant, Souchetti, imperial, c. Of the American seedling varieties may e mentioned the Allen, Catawissa, Cushing, rench, and Brinkle's orange. All the sorts row freely in any good garden soil, especially f it be moist; if dry, the berries are small and alf-grown. The ground should be kept light nd rich to promote the sending out of the urface roots, and supernumerary suckers hould be removed. Pruning is performed in utumn or early spring, cutting out all the ead stems. The plants do best when secured o firm stakes; they may be trained advan- ageously to fences or walls, a sunny or shaded xposure affecting the time of ripening the uit. The raspberry is well adapted to small ardens, as it will grow readily under the shade f trees; and when raised for the market in pen spaces the yield is abundant and profit- ble.—The wild red raspberry (*R. strigosus*, x.) closely resembles the European species, produces a fine-flavored but tender watery uit, and grows in the greatest profusion upon e hillsides of New England, ripening in ly and August. It even grows well in the ities, and some varieties of much repute ave been observed. The black raspberry or imbleberry (*R. occidentalis*, Linn.) is remarkable for its blue or glaucous stem and foliage, and its purplish black and firm, pleasant-tasted berries, bearing abundantly, and repaying any care bestowed upon it. The cloudberry (*R. chamæmorus*, Linn.) is found in northern New England, on the White mountains and similar elevations, and is the same species which in Lapland is esteemed as a valuable food. The purple-flowering raspberry (*R. odoratus*, Linn.) is a common plant in the northern states, and is conspicuous for its large showy blossoms, which make it a fine ornamental shrub for the garden. It has large, simple, lobed leaves; its fruit is large, flat, dry, and agreeably acid, but rare.

RASSE. See CIVET.

RASTADT, a fortified town of Baden, on the river Murg, about 9 m. S. S. W. from Carlsruhe; pop. 6,500. In 1714 a treaty of peace was signed here by Prince Eugene and Marshal Villars, which put an end to the war of the Spanish succession. The second congress of Rastadt met Dec. 9, 1797, to negotiate a treaty of peace between France and the German empire. It was not dissolved until April, 1799; and when the two French ambassadors, Roberjeot and Bonnier, set out on their return, they were assassinated by Austrian horsemen a short distance from the city. Rastadt is one of the strong places of the German confederation; its defensive works are of great strength and extent. In May, 1849, the garrison having mutinied, the place became the principal and last stronghold of the German republicans; but after a short resistance under Mieroslawski it surrendered to the troops of the prince of Prussia in July.

RAT, a well known rodent, the type of the sub-family *murinæ*. In the murine tribe of this sub-family, confined originally to the old world, belong the common house rats. The brown or Norway rat (*mus decumanus*, Pall.) has a body 8 to 10 inches long, and the tail 6 to 8 inches, scantily covered with hair and with about 200 rings; the color above is grayish brown mixed with rusty, grayer on the sides, and ashy white below; the upper surface of the feet dirty white. This species, originally from India and Persia, entered Europe through Russia, appearing in the central countries about the middle of the 18th century; it was brought to America about 1775, and has since greatly increased in numbers, driving out here as in Europe the black rat which had been previously introduced; it is now generally distributed over the world, having been transported in ships, and most abundantly near the sea coasts. Its haunts are well known to be cellars, sewers, canals, docks, and similar dirty places, wherever it can make a burrow or find abundant food; it is a great household pest, and so prolific that its devastations are sometimes very great; it breeds from 3 to 5 times a year, having 12 to 15 at a birth, the males always being the most numerous. Not only the black rat, but other species indigenous to the old world, are driven off or destroyed by it; the dead and even living persons are attacked by it when hard pressed; it is not only pursued by man, dogs, and cats, but the stronger will kill and devour the weaker of its own species. The black rat (*M. rattus*, Linn.) is 7 or 8 inches long, with a tail of 8½; the color is very dark, often nearly black, with numerous long hairs projecting from the short and soft fur, plumbeous beneath, and the feet brown; it has a slighter form than the brown rat, with the upper jaw more projecting, the ears larger, and the tail much longer in proportion. It is not very strong, but exceedingly active; being rather timid, it is exterminated by the larger and fiercer brown rat; the habits of the two species are much the same, but the black rat is less a burrowing animal, and prefers the upper parts of houses to cellars and low dirty places. It used to be the common house rat in Europe and warm countries, until driven off by its congener; it appears to have been brought to the new world about the middle of the 16th century; it came originally from central Asia; like the preceding species it is omnivorous. The roof or white-bellied rat (*M. tectorum*, Savi) is about 6½ inches long, and the tail about 8, with 240 rings; it is colored above like the brown rat, the lower parts and upper surface of feet yellowish white; the head is rather blunt, the eyes large, whiskers long and black, ears very large, and the thumb rudimentary. It came originally from Egypt and Nubia, thence passed to Italy and Spain, and from the last to America in the 15th century; it is common in Mexico and Brazil, and in the southern states, but is rarely found above North Carolina; it is fond of inhabiting the thatched roofs of houses, whence its name; it is the same as the *M. Alexandrinus* (Geoffr.) and *M. Americanus* (Seba). Some of the East Indian rats are far larger than any of these; the giant rat of Bengal and the Coromandel coast (*M. giganteus*, Raffles) has a body 13 inches long and a tail as much more; this is very destructive in gardens and granaries, devouring chickens and ducks, undermining houses, and piercing the mud walls; this is the largest of the sub-family, a male weighing as much as 8 lbs.; it is often eaten by the lower caste Hindoos.—All these rats are very fond of fighting, and with their omnivorous habits are decidedly murine cannibals, eating not only their conquered brethren but their young. Though living in the filthiest places and in the foulest air, they always have a sleek coat, and take the greatest pains to clean themselves, licking the paws in the manner of a cat; during mastication the jaws move very rapidly; they drink by lapping; when asleep the body is coiled in a ball, with the nose between the hind legs, and the tail curled around the outside, leaving only the ears out ready to catch the least sound of danger; as food fails they migrate in companies from one place to another. There are more muscles in a rat's tail than in the human hand; this most useful appendage, with its chain of movable bones and numerous muscles, is covered with minute scales and short stiff hairs, rendering it prehensile, and capable of being employed as a hand, balancer, or projecting spring. The teeth are long and sharp, but there is nothing specially dangerous in wounds made by them; their strength enables them to gnaw ivory, as dealers in this article well know; in fact, even in Africa, elephants' tusks are found gnawed by rats, squirrels, porcupines, and perhaps other rodents, as long as any gelatine is contained in them. They are very subject to tumors of the skin, which often end fatally; they also perish soon without water. Persecuted as these animals are, they have their uses, especially as scavengers for devouring refuse matters which would otherwise engender disease, as in tropical climates or in large cities, in the sewers of which they live in legions; their skins are employed for various purposes, as in the manufacture of the thumbs of gloves, but are too delicate for any article requiring much strength. The Chinese and other Asiatic nations, and many African tribes, consider the flesh of rats a great delicacy; and arctic travellers have often found them a welcome addition to their bill of fare.—In the sigmodont tribe of the *murinæ*, belonging entirely to the new world, beside the genera noticed under MOUSE, may be mentioned *neotoma* (Say and Ord); in this the fur is soft and full, the form rat-like, the tail long and more or less hairy; ears very large and nearly naked; molars rooted; heels hairy. It is peculiar to North America, and found in the United States except New England; some of the species are much larger than house rats, and are rather handsome animals. The Florida or wood rat (*N. Floridana*, Say and Ord) is about 8 inches and the tail 6, the short stiff hairs of the latter not concealing the scaly rings; the color above is plumbeous mixed with dark and yellowish brown, lighter on the sides, beneath and the feet white; tail dusky above, below white; the head is sharp. It is abundant in the southern Atlantic and gulf states, and is found occasionally in the west; the habits vary much in different localities, living in some places in the woods, in others under stones or in the ruins of buildings; in swampy districts it heaps up mounds 2 or 8 feet high, of grasses, leaves, and sticks cemented by mud; sometimes the nest is made in the fork or the hollow of a tree. It is crepuscular, very active and an excellent climber; the food consists of corn, nuts, cacti, crustaceans, mollusks, and various roots and fruits; the disposition is mild and docile; from 3 to 6 young are produced twice a year. The bush rat (*N. Mexicana*, Baird) is rather smaller, light brown above, fulvous on the sides, under parts and feet white; tail hairy. Larger species are found west of the Rocky mountains, very destructive to the furs, blankets, and stores of the trappers; for an account of these see vol. viii of the "Reports of the Pacific Railroad Expedition." In the bone caves of Pennsylvania have been found the remains of a species whose body must have been at least 15 inches long.—In the genus *sigmodon* (Say and Ord) the general appearance is that of a large field mouse; the body is stout, the hair long, the muzzle blunt and hairy except on the septum; the upper lip slightly notched; thumb rudimentary; soles naked, with 6 granular tubercles; incisors stout, the upper much rounded; ears and tail moderate; molars rooted, with a plane surface, the last 2 lower with the enamel in the form of an S, whence the name. The genus is confined to the southern parts of the United States. The best known species is the cotton rat (*S. hispidus*, Say and Ord), about 5 inches long with a tail of 4; the color above is reddish brown, brightest on the sides, lined with dark brown, and under parts grayish white; the hair is long and coarse, and the claws very strong. It is more abundant in the southern states than the meadow mice in the north, living in hedges, ditches, and deserted fields, and consequently doing but little damage to the planter. It is gregarious, feeding on seeds of grasses and leguminous plants, and also on flesh; it picks up wounded birds and small mammals, crawfish, and crabs; it is very fierce and pugnacious, the stronger killing and devouring the weaker, and the males often eating the young; it is also very fond of sucking eggs. Nocturnal in habit, it is seen by day in retired places; it digs very extensive galleries, not far from the surface, a family in each hole; very prolific, it breeds several times a year, having 4 to 8 in a litter; it swims and dives well. It received its name not from any injury it does to the cotton plant, but from its lining the nest with this substance, which it is said to collect in large quantities. It is preyed upon by foxes, wild cats, hawks, and owls; it is not found north of Virginia.

RATAN. See Rattan.

RATAZZI, Urbano, an Italian statesman, born in Alessandria, Piedmont, June 29, 1808. He settled as an advocate in Turin, and afterward distinguished himself by his learning and his eloquence at the court of appeal in Casale. After the revolution of 1848 he was elected from the college of Alessandria to the chamber of deputies at Turin, in which body he took his place among the liberals. After the defeat of Custozza (July 25) Charles Albert called him into the ministry, which was obliged to resign 8 days afterward. Ratazzi then joined the opposition under Gioberti, on whose triumph, Dec. 16, he received the post of minister of the interior and subsequently of justice. He however separated from Gioberti on the proposition to send a Piedmontese army to Rome for the purpose of restoring the pope; and this project, sharply rejected by the parliament, hastened the fall of Gioberti. Ratazzi however retained his position in the ministry until the abdication of Charles Albert, when he found himself again in the ranks of the opposition. He afterward joined the party of moderate reformers, and became vice-president and in 1852 president of the chamber; and in 1854 he reentered the ministry with the portfolio of justice, under the presidency of his former opponent, Count Cavour. On Cavour's retirement after the peace of Villafranca Ratazzi became minister of the interior, but resigned in July 1860 when Cavour returned to office.

RATEL, a plantigrade mammal of the badger family, and genus *mellivora* (Storr), named honey badger from its fondness for honey. The size is about that of the badger, but rather heavier, and with less projecting nose; the cheek teeth, according to Owen, are premolars $\frac{3-3}{3-3}$ and molars $\frac{1-1}{1-1}$, with no tuberculate tooth in the lower jaw; the feet are short and plantigrade, the anterior with large claws; the hair is long and rigid, and the skin tough. The African ratel (*M. Capensis*, Storr) is gray above and black below, the two colors separated by a white line. It inhabits the Cape of Good Hope, the Mozambique coast, and other parts of southern Africa, burrowing in the ground for its dwelling and also in search of the nests of wild bees, against whose stings its loose and leathery hide is ample protection; according to the Hottentots it is guided to these nests by the honey guide, a bird of the cuckoo family and genus *indicator* (Vieill.). It also eats birds, rats, snakes, and flesh of almost any animal, living or dead. The Asiatic ratel (*M. Indica*, Storr) much resembles the African, but has a shorter tail and no white lateral stripe; it is found in India, in the high banks of the Ganges and Jumna; it is nocturnal in habit, prowling around in search of food, and often preying upon imperfectly buried human bodies. It is a strong and bold animal, and a good but slow climber on walls or trees; it burrows with great facility, throwing the earth backward with the fore paws like a dog.

RATIO. See Proportion.

RATIONALISM. See German Theology.

RATISBON (Ger. *Regensburg*; anc. *Ratisbona*), a town of Bavaria, capital of the Upper Palatinate, situated on the right bank of the Danube, opposite its junction with the Regen, 65 m. N. N. E. from Munich; pop. in 1858, 26,656. The Danube is here crossed by an old stone bridge about 1,100 feet long. Ratisbon is a very ancient town, surrounded by dilapidated ramparts and entered by 6 gates. The cathedral is one of the finest Gothic churches in Germany; it was founded in 1275, but the greater part of it appears to have been constructed in the 15th century. Adjoining the cathedral there are two older churches, one, now used as a baptistery, is supposed to date from the 10th or 11th century, and the other to be still more ancient. A massive square tower stands near the cathedral, supposed to be a remnant of an ancient Roman fortress. The manufactures are of considerable importance, and include cotton, paper, earthenware, steel, iron, &c. Ship building is extensively carried on. Ratisbon formerly enjoyed the exclusive right of the navigation of the Danube between Ulm and Vienna, but this privilege has been abolished. At Donaustauf, on the Danube, about 6 m. from Ratisbon, is the Walhalla, a Doric marble temple built after the model of the Parthenon at Athens, for the reception of statues and busts of distinguished men of Germany. King Louis of Bavaria founded it in 1830, and it was completed in 1842.—Ratisbon was a town of importance in the 2d century, and at a later period became the capital of the dukes of Bavaria. In the 12th century it became a free imperial city, and from 1663 to 1806 it was the seat of the German diet. In 1803 it was given to the archbishop of Mentz, and in 1810 it became a possession of Bavaria.

RATTAN, or **Ratan** (Javanese, *rottang; Malay*, *rotan*), the long slender leaf stalk of various species of the *calamus*, of the natural order *palmæ*, a product of the forests of the eastern archipelago, especially of the islands of Sumatra and Borneo, and the Malayan peninsula. The palm which furnishes most of the rattans of commerce is the *calamus rotang*, a bush, the slender whip-like shoots of which find a support among the foliage of other adjacent plants by means of the prickles with which their extremities are armed. The canes are largely collected for numerous useful purposes, and are exported in great quantities to almost all parts of the world, and particularly to China. Their peculiarity consists in great flexibility and strength, uniform size in lengths of 16 feet or more, and the evenness with which they may be split up into small strips, qualities which adapt them for a singular variety of uses. The eastern nations make them into chairs and other articles of furniture, baskets, sieves, &c., and also into hats and shoes. They answer as a substitute for ropes, and the Chinese thus use them with much neatness for securing tea chests, &c. They also plait them together to form mats of many varieties and serving many purposes. In the United States and Europe rattans are largely employed for the bottoms of chairs, being split into narrow strips and woven together in open work. They are also a cheap substitute for whalebone. As imported they come in bundles of 50 canes, each one about 16 feet long and bent double in the middle. The leaves and the natural epidermis or bark are stripped from them when they are collected in the forests, the method being after cutting them to draw each one quickly through a notch made for the purpose in a tree. The stems are thus left clean and naked, and protected by the hard silicious glazing with which they are coated. The best have a bright pale yellow color, of size less than a man's little finger, and cannot be broken without great difficulty. They are obtained so cheaply in Borneo, that they are sold to the Chinese junks for about 5 cents per hundred. In Bengal and in China they are disposed of by the picul or by weight at a large advance.

RATTLESNAKE, a well known American venomous serpent, the type of the family *crotalidæ*, which includes several species, all characterized by a deep pit lined with small plates on each side, beneath and usually a little behind the nostrils. In the genus *crotalus* (Linn.) the head is very large, flattened above and triangular, scaly on the crown, with small shields on its sides and the nose; eyes large and brilliant; teeth very small, but the true maxillaries, which are small and attached to the cranium by a small pedicel and by ligamentary union, have a single pair of long curved fangs, laid flat during inaction, but erected when the mouth is opened; these fangs are channelled for the conveyance of the poison secreted by a gland on each side of the head, beneath and behind the eyes; behind the fangs are the rudiments of others, which are developed as occasion requires; there are also 2 rows of small fixed teeth on the palate; the belly is covered with broad shields; the trunk and tail are scaly above, and nearly all the subcaudal scutes simple. The last 3 to 8 caudal vertebræ coalesce to form a single terminal conical and compressed bone, covered by muscle and a thick spongy skin which secretes the pieces of the rattle, an appendage of loosely articulated horny segments, whose rattling noise has given the popular name to this genus; the rattle may consist of 20 or 30 pieces, the smallest at the end; they are securely strung together, each consisting of 3 annular portions, the basal ring of one grasping the 2d of the preceding, and this again enclosing the 3d of the joint next the one preceding, all that is visible of the rattle externally being the surface of the basal projecting ring of each joint; the first only has a vital connection with the skin; this apparatus is made to vibrate by the muscles of the tail, with a quivering motion and a sound resembling that of peas shaken in a dry pod. It is popularly but erroneously believed that the age of the snake can be estimated by the number of the rattles; though these may increase with age, their fragility is such that many may be lost from accident; and moreover more than one may be added annually, according to the vigor, food, state of captivity, &c., of the animal; 20 are not unfrequently seen in large specimens, but it would be incorrect to conclude from these that the snake was neither more nor less than 20 years old. As the bite of these reptiles is speedily fatal to small animals, it has been generally believed that the use of the rattles is to warn animals and man of its vicinity; but, as other equally and even more dangerous species have no such apparatus, it is more likely that its use is to startle the squirrels, birds, and other creatures upon which it preys from their retreats, and bring them within the reach of its spring, or for some other purpose for its own welfare rather than the safety of man. Dangerous as they are, they rarely attack man unless provoked, and are fortunately sluggish in their movements, unable to spring except from a coil, and are disabled by slight blows. They are viviparous, the eggs being retained until hatched, and the young expelled alive; in winter they retire to holes in the ground, and there remain torpid, several intertwined with each other; they are unable to climb trees in pursuit of prey, and do not follow a retreating animal which has escaped their spring. They are said to be fond of music, like many other serpents. Some Indian tribes hold them in great reverence, and are afraid to kill them, fearing that the spirit of the slaughtered animal will excite its living relations to avenge its death. They are capable of attaining to a considerable age, and are tenacious of life under circumstances speedily fatal to most other animals.—The most common is the banded rattlesnake (*C. durissus*, Linn.), 4 to 6 feet long, ash-colored above with irregular transverse dusky bars, confluent near the tail; vertebral line yellowish, the sides tinged with the same; the body is thick and robust and the tail short and thick; in a specimen about 4 feet long the head was 2 inches, the body 40, the tail 3½, and 9 rattles 2 inches, the greatest circumference being 6 inches; there were 177 broad abdominal plates, and 25 under the tail; in the young the tail is black. It is generally distributed throughout the United States, from lat. 45° to the gulf of Mexico, and from the Atlantic to the Mississippi and Red rivers; it preys principally on rabbits, squirrels, rats, and small birds, quietly waiting for them to come within its reach, its bite proving fatal to animals of this size in less than a minute, when the snake is in full vigor. It is now rarely met with in the northern states, except in uncultivated and rocky places, remote from dwellings; it is more common in the western states, where its fat is highly prized as an antidote to its bite, and also for rheumatic and neuralgic pains; cattle are often bitten by it, and it is the custom there to cast them and bury the wounded part in the mud, recovery rapidly taking place; this shows the comparatively little danger for a large animal, as there can be nothing curative in the application made. The diamond or water rattlesnake (*C. adamanteus*, Beauv.) is dark brown or dusky above, with a series of large rhomboidal spots continuous from head to tail; abdomen dirty yellowish white; the mouth is large, the neck small and contracted, and the body long and thick; it is the largest of the genus, and may attain a length of 8 feet; in one about 6½ feet long the head was 2¾ inches, the body 60, the tail 2½, and the rattles 3 inches; abdominal plates 172, and 25 subcaudal. It frequents damp and dark places, always near water, though not living in it; it is one of the most hideous and sullenly ferocious of the family; its range is very limited, from North Carolina to East Florida, on the sea coast. The *C. horridus* (Linn.) is a native of the warm parts of South America; it attains a length of 5 or 6 feet and the thickness of a man's wrist; the color is yellowish brown varied with *darker*, on the lower parts lighter; there are wide *lozenge*-shaped spots along the back edged with white, with light stripes and other smaller and less distinct spots on the sides; brownish black bands between the eyes, and from the top of the head along the neck. It is found only in dry, rocky, elevated regions, covered with thorns and bushes; the negroes esteem its flesh a delicacy; it often bites and destroys cattle coming near its retreat, the poison being more virulent in tropical climates. —The genus *crotalophorus* (Gray) seems to connect *crotalus* with *trigonocephalus* (copperhead), having the rattles of the former and the plates on the head of the latter. The small or ground rattlesnake (*C. miliarius*, Gray) is dark gray above, with a brownish red vertebral line interrupted by a row of subquadrate black spots margined with yellow; a double series of black spots on each side, the upper larger but less distinct, and a white streak backward from the eyes. It is generally from 16 to 18 inches long, and is common in the United States as far N. as lat. 35°, in dry places among leaves, preying on field mice and small birds; its bite is fatal to small animals, but not to man. The prairie rattlesnake (*C. tergeminus*, Say) is a little over 2 feet long; it is cinereous above, with a triple series of dark brown spots, and a double series of dusky spots below; it is fond of hiding in the holes of the prairie dog (*cynomys*), on the young of which it chiefly feeds; it occurs in the country near the Rocky mountains and the sources of the Missouri. Other species are described by Dr. Holbrook, and by Baird and Girard.—The poison gland is compressed by the temporal muscle during the act of striking; there is a very extensive communication of the glandular tissue with the vascular system, the blood vessels surrounding the secreting tubes in a capsular manner. Microscopically the poison appears as a limpid hyaline serum, with crystals of ammonio-magnesian phosphate, according to Dr. W. I. Burnett. According to Dr. Mitchell it is yellow, acid, glutinous, of a specific gravity of 1.04; devoid of taste, smell, and acridity; beginning to coagulate at 140° F., and soluble in water. It consists: 1, of an albuminoid substance, coagulable by pure alcohol but not by a heat of 212° F., called by him crotaline, the poisonous element; 2, of a non-poisonous albuminoid compound, coagulable both by heat and alcohol; 3, of a yellow coloring matter and an undetermined substance, both soluble in alcohol, traces of fatty matter and free acid-saline bodies, chlorine, and phosphates. No temperature from zero to 212°, nor acids and alkalies at moderate temperatures, nor alcohol, chlorine, nor iodine, destroy the poisonous property of the venom. This fluid is fatal even to the bitten snake; it destroys the vitality of the blood and its power of coagulation, as by a lightning stroke; it probably acts as a powerful sedative through the blood on the nervous centres; hence the best antidotes are active stimulants, especially alcohol in some form; and, *vice versa*, intoxication may be neutralized by taking this poison into the stomach in the form of pills. The poison varies in intensity according to season, climate, and vigor of the animal, being most active in tropical regions and in warm weather, when it has been long retained or the animal is greatly irritated; cold-blooded animals generally suffer little from its bite, and pigs kill and devour it with impunity and avidity, their covering of fat preventing the introduction of the poison into the circulation; its virulence is soon exhausted by rapidly succeeding bites, as has been proved by experiments on chickens and rats; as its secretion goes on for some time after death, experimenters should be careful in their manipulations about the fangs and poison apparatus. For details on the habits of these serpents, on the anatomy of the parts concerned in the secretion and expulsion of the poison, and in the infliction of the wound, and for a full enumeration of genera and species, with illustrations and copious bibliography, see a memoir in vol. xii. of the "Smithsonian Contributions to Knowledge" (1860), by S. Weir Mitchell, M.D., and an abstract of the same in the secretary's report for 1860 (8vo., Washington, 1861).—The long list of remedies considered efficacious, in various parts of the country, against the bite of the rattlesnake, indicates that the danger is not so great from it as is generally supposed. When the poison is introduced directly into a large vein, especially in the neck, groin, or armpit, the result would probably be fatal, but many cases recover under every variety of treatment; the favorable result in each case, as a matter of course, is attributed to the remedy employed, whether that be whiskey, sweet oil, rattlesnake's grease, ammonia, caustic, snakeroot, or other domestic application; the fact probably is that, though small animals, children, and persons of feeble constitution will die from the effects of the bite, large animals and vigorous men will generally recover, unless the virus be introduced directly into some large vessel near the heart. The indication is to prevent the poison from entering the circulation, by suction with the mouth or by cupping glasses, the former being perfectly safe and always practicable immediately, as the system is not affected through the mucous membranes. Ligatures around the limb, and excision and cauterization of the wound by fire, caustic, or ammonia, should be employed also; these should be practised as soon as possible, and large doses of alcoholic stimulants administered. The antidote of Bibron, a preparation of bromine, has been highly extolled. The American Indians apply cataplasms of chewed tobacco, snakeroot (*polygala senega*), button snakeroot (*liatris spicata*), pleurisy root (*asclepias tuberosa*), rattlesnake root (*prenanthes alba*), western black ash (*fraxinus juglandifolia*), water plantain (*alisma plantago*), tall speedwell (*leptandra Virginica*), and rough hawk weed (*hieracium Gronovii*).

RAUCH, Christian Daniel, a German sculptor, born in Arolsen, in the principality of Waldeck, Jan. 2, 1777, died in Berlin, Dec. 3, 1857. He was of humble origin, studied under Valentin, from whom he learned the art of carving the ordinary bass-reliefs on gravestones, and under Ruhl of Cassel. At Berlin, whither he next repaired, he was induced by poverty to accept a position as a royal domestic, which had been occupied by a deceased brother, and for a time his art studies were laid aside. But aspiring to a higher walk in life than this, he secretly undertook to model from recollection a bust of Queen Louisa. His success gained the queen's attention, and under her patronage he was sent to Dresden, and in 1804 was enabled to go to Rome to complete his education, where, aided by the advice of Canova and Thorwaldsen, he made rapid progress in his art. His first work was a portrait statue in marble of the daughter of Wilhelm von Humboldt, who was one of his earliest friends and patrons; and under the influence of the antique sculpture which surrounded him he executed two admirable bass-reliefs, "Hippolytus and Phædra" and "Mars and Venus wounded by Diomedes," beside busts of the king and queen of Prussia and other notable persons. In 1811 he visited Berlin with other artists to compete for the monument of Queen Louisa, who had died the year previous; and his design having been accepted, he returned to Italy, and for two years was exclusively employed in the execution of the celebrated recumbent statue of the queen now in the mausoleum at Charlottenburg. It made him at once famous throughout Germany, and commissions for portrait busts and statues poured in upon him. In 1815 the king of Prussia commissioned him to execute statues of Generals Scharnhorst and Bülow, and within the next 10 years he wrought with his own hands upward of 70 busts in marble, of which 20 were of colossal size, many of them portraits of eminent Germans. His forte however lay in historical monumental works, and his greatest achievements were the public statues in marble and bronze, of which almost every considerable city in Germany contains one or more. Among these were the statues of King Maximilian at Munich, of Francke at Halle, of Blücher at Breslau, of Albert Dürer at Nuremberg, of Luther at Wittenberg, of the old Polish monarchs Miecislas I. and Boleslas I. at Posen, of Goethe, Schiller, and Kant, the colossal Victory for the Walhalla near Ratisbon, &c. The crowning work of his life, however, was his colossal monument in Berlin to Frederick the Great, commenced in 1830 and inaugurated with great pomp in May, 1851. The statue of the king is an equestrian one, and the 4 sides of the lofty granite pedestal on which it is placed are covered with historical and allegorical representations in high relief—a species of sculpture in which Ranch excelled—and surrounded by detached statues of the distinguished men of his reign. Rauch's last and one of his most impressive works was a model of "Moses Praying between Aaron and Hur," on which he labored until within a few weeks of his death. As a portrait and historical sculptor he stood at the head of his profession.

RAUCH, Frederick Augustus, D.D., a German philosopher and divine, born at Kirchbracht, Hesse-Darmstadt, July 27, 1806, died March 2, 1841. He was graduated at the university of Marburg in 1827, then studied one year at Giessen, after which he was assistant teacher in a literary institution in Frankfort, and still later spent a year in the university of Heidelberg. In his 24th year he became extraordinary professor in the university of Giessen, and soon afterward ordinary professor in the university of Heidelberg. Before, however, he assumed the duties of his new appointment, he incurred the displeasure of the government by too free an expression of his political sentiments, and was obliged to seek safety in flight. He arrived in America in 1831, spent several months at Easton, Penn., in the study of the English language, and in June, 1832, was ordained to the ministry, and called to York, Penn., to take charge of a classical school in connection with the theological seminary of the German Reformed church. In 1836 he was called to the presidency of the newly founded Marshall college, Mercersburg, Penn., acting at the same time as professor of biblical literature in the theological seminary which had been removed to that place. He continued in this double office up to the time of his death. In 1840 he published his "Psychology," which has passed through several editions, and is used as a text book in mental philosophy in colleges. He had in course of preparation a work on "Christian Ethics," which he did not live to finish. A volume of his sermons, edited by the Rev. Dr. Gerhart, was published in 1856 under the title of "The Inner Life of the Christian."

RAUMER, Friedrich Ludwig Georg von, a German historian, born in Wörlitz, near Dessau, May 14, 1781. He was educated at the universities of Halle and Göttingen, began to practise law in 1801, and after having filled several offices obtained in 1810 the place of counsellor in the cabinet of the chancellor Hardenberg. He had begun his literary labors in 1806 by the publication of a work entitled "Six Dialogues on War and Commerce," and this was followed by "The British System of Taxation" (1810), "The Speeches of Æschines and Demosthenes upon the Crown" (1811), and *CCI. Emendationes ad Tabulas Genealogicas Arabum et Turcarum* (1811), which procured for him a professorship in the university of Breslau. He next published a "Manual of remarkable Passages from the Latin Historians of the Middle Ages" (Breslau, 1813), and "Autumn Journey to Venice" (2 vols., Berlin, 1816); and in 1819 he was made professor of political economy and history in the university of Berlin. He was for a long time a member of the board of censors and a member and secretary of the Berlin academy of sciences until 1847, when, in consequence of the unfavorable reception of a eulogium delivered by him upon Frederic II., he was forced to withdraw from both positions. The city of Berlin, however, elected him to the municipal council, and in 1848 sent him to the parliament at Frankfort, after which he was for a short time ambassador to Paris. In 1853 he retired from active life, and received the title of professor emeritus in the university of Berlin. Among his historical and political works are "Lectures on Ancient History" (2 vols., Leipsic, 1821); the "History of the House of Hohenstaufen and its Times" (6 vols., 1823–'5); and "History of Europe from the End of the 15th Century" (vols. i.–viii., Leipsic, 1832–'50). His "England in 1835" was translated by Mrs. Austin (3 vols., London, 1836). A collection of his minor works appeared under the title of *Vermischte Schriften* (3 vols., Leipsic, 1852–'4). He travelled in America in 1843, and wrote "America and the American People," translated by W. W. Turner (New York, 1846).

RAVAILLAC, François, the assassin of Henry IV. of France, born in Angoulême about 1578, executed May 27, 1610. He was first employed as a lawyer's clerk, and then as a schoolmaster; but having been cast into prison on account of some offences, he fell into a gloomy fanaticism. He went to Paris, and there became a member of the order of the Feuillants, but was expelled from it as a fanatic and fool, and afterward returned to Angoulême, where his unhappy state of mind manifested itself in the most intense hatred of Protestantism. With this feeling he determined to undertake the murder of Henry IV., whom he was taught to consider the great enemy of the Catholic faith. He went to Paris, but for some time had no opportunity of meeting with the king. On May 14, 1610, however, about 4 P. M., the king drove to the arsenal in order to visit Sully, who was sick, and to inspect the preparations for the crowning of the queen. When in the narrow street La Ferronnerie the carriage was obliged to stop, as the way was blocked up by market wagons. The king was sitting on the left side next to the duke of Epernon, when Ravaillac, throwing himself upon the right hind wheel, struck twice at him with a dagger. The first time he failed, but the second he plunged the knife into the heart of the king. The assassin fled, but was immediately caught with the knife in his hand, acknowledged his deed, and after a trial before the parliament of Paris was torn to pieces by horses with unexampled tortures.

RAVEN, the largest of the *corvidæ* or crow family, and the type of the genus *corvus* (Linn.). In this genus the bill is long and very strong, and arched; the nasal feathers are lengthened and reach about to the middle of the bill, and the nostrils are large, circular, and overhung behind by membrane; the gape without bristles; wings long and pointed, when closed reaching nearly to the tip of the tail and far beyond the under coverts; the 2d quill longer than the 1st, and the 3d and 4th the longest; primaries 10, the outer 4 sinuated on the inner edge; tail short and nearly even; tarsi longer than middle toe, scaled in front. The American raven (*C. carnivorus*, Bartram) is about 25 inches long with an alar extent of 50, and the bill 3 inches; the female is a little smaller, but in other respects like the male. The plumage is compact, glossy black with violet and greenish reflections; the feathers of the chin and throat, as in all ravens, are elongated, stiffened, narrow, lanceolate, and with very distinct outlines. It is found over the entire continent of North America from Labrador to the gulf of Mexico, in some places migratory, but in others (as at Lake Superior and in Canada) braving the cold of the severest winters; it is most abundant in rocky districts, near the banks of lakes and rivers, and in thinly peopled regions. It is generally seen alone or in pairs, but sometimes in small flocks after the breeding season; the flight is rapid, elevated, and protracted, often sailing for hours at a time at a great height; on the ground the gait is grave and dignified, with frequent opening of the wings. It is truly omnivorous, but by preference carnivorous, eating small animals of all kinds, eggs and young birds, carrion, dead fish, mollusks, crustaceans, insects, nuts, and berries. It is very wary and cunning, and is rarely caught in traps or shot by the hunter, but it often falls a victim to the poisoned baits set by the trappers for the fur-bearing animals. It breeds, according to latitude, between January and June, making a rude nest on inaccessible cliffs, repairing the same for years in succession; the eggs are 4 to 6, 2 inches long, light greenish blue with numerous light purple and yellowish brown blotches, especially at the larger end; incubation lasts about 3 weeks, and the young remain in the nest several weeks before they are able to fly, fed at first on the half digested food disgorged by the parents; only one brood is raised in a year, and this is bravely and successfully defended against the largest birds of prey. It is easily domesticated by kindness, and becomes much attached to its master, following him like a dog; it can be taught to imitate the human voice and to pronounce a few words with great distinctness; when irritated or wounded, it strikes savagely with bill and claws. Its flesh is tough and unfit for food; it disgorges indigestible substances, as bones, hair, and feathers, like birds of prey. Like others of the genus, this species varies much in size and proportions according to locality, those of the south, contrary to the general rule, being larger than the northern individuals of the same species; this fact has led some to think that the Colorado raven (*C. cacalotl*, Wagl.) is only a southern variety of the *C. carnivorus*, the chief differences being a slightly larger size, longer wings and tail, and a western and southern habitat exclusively. The white-necked raven (*C. cryptoleucus*, Couch), from Mexico and Texas, is about 21 inches long, with the feathers of the neck all round, back, and breast, snow-white at the base.—The European raven (*C. corax*, Linn.) very much resembles the American in size and proportions, and the two have been regarded by Audubon and others as the same; most modern naturalists, however, consider them distinct; it is about 26 inches long and 52 in alar extent. It is a very interesting bird on account of its habits, and its historical, economical, and superstitious relations; it is very grave and dignified, sagacious, courageous, and powerful; its beak is as well adapted for tearing flesh as is that of rapacious birds; though wary and distrustful, it is docile and affectionate when domesticated; it possesses an excellent memory, and a decidedly thievish disposition. The color is black, with steel-blue and purplish or violet reflections; its form is symmetrical and its proportions fine. It is proverbially long-lived, and has been known to attain the age of about 100 years; it is spread extensively over Europe, and allied species are found in Africa and Asia. It is voracious and omnivorous, but particularly fond of carrion, whether of flesh, fish, or fowl, dead from disease or accident; it will attack an animal of the size of a sheep when in a helpless or dying condition; it is said to destroy young lambs, and certainly makes great havoc among half-grown hares and rabbits, young and full-fledged birds, and eggs; on finding a carcass the first attack is upon the eyes and tongue, and then upon the abdomen to drag out the intestines; in autumn it sometimes commits serious depredations upon barley fields. The flight is at times very high, enabling them to see to a great distance, and to watch for and follow any companions which have chanced to spy their favorite food, explaining the rapid collecting of a large number in a short time; they have no special acuteness of smell, but are guided to their food by the sense of sight; the voice is a harsh and disagreeable croak. They are usually seen alone or in pairs, except when drawn together by a large carcass in the field or on the shore; the nest is made in lofty trees or in holes of inaccessible cliffs, and the same one is used year after year; a fetid odor issues from the body, probably on account of their carrion food. Farmers and shepherds like to have them breed on their premises, as they keep off eagles, cats, dogs, and similar unwelcome visitors. This was considered a bird of ill omen by the ancients, and was one whose movements were watched by the augurs with great attention; and it has been generally looked upon with superstitious fears, on account of its black hue, mournful croak, fetid odor, and disgusting habits. It by preference inhabits the most desolate places. In America, at least, there seems to be a natural antipathy between the raven and the crow; where the former abounds, as about Lake Superior, the latter is very rarely seen, and *vice versa*.

RAVENNA, a legation of the Papal States, forming part of the Romagna, which was annexed to the kingdom of Sardinia in March, 1860. It is bounded N. by the legation of Ferrara, E. by the Adriatic, S. E. by the legation of Forlì, S. and S. W. by Tuscany, and N. W. by Bologna; area, 674 sq. m.; pop. 175,994. It has a fertile soil, abounds in pasturage, and produces grain, wine, oil, and silk.—Ravenna, the capital, is situated in a marshy plain on the river Montone, a few miles from the Adriatic; pop. 24,000. The principal buildings are the cathedral, the church of Santa Maria della Rotonda, formerly the mausoleum of Theodoric, king of the Ostrogoths; the basilica of San Vitale; the churches of St. John the Baptist and St. John the Evangelist, built in the 5th century by the empress Galla Placidia; and the remains of the palace of Theodoric, occupied after him by the exarchs. Ravenna is the seat of an archbishop. The chief pursuits are the culture of the vine and the rearing of silkworms, with the spinning and weaving of silk. Ravenna was once situated on the Adriatic in the midst of marshes, but it is now some distance from the sea, the alluvial deposits and the sand thrown up by the sea having filled the lagoons and canals which surrounded and intersected the city. Between Ravenna and the sea is the *Pineta*, a remarkable forest of pines extending for many miles along the coast. This existed as early as the 6th century, and has been spoken of by Dante, Boccaccio, Dryden, and Byron.—The city appears to have been founded by the Umbrians. It is not mentioned in history until a late period of the republic, but during the civil wars between Julius Cæsar and Pompey and between Antony and Octavius it held a prominent position. Augustus raised it to still greater importance by building a new port called Portus Classis, or simply Classis, capable of containing 250 ships of war, and making it the station of the fleet guarding the Adriatic. The natural strength of its position contributed to render it an important military post, and in A. D. 404 Honorius made it the abode of the western emperors. It remained the imperial residence until the fall of the western empire, then became the capital of the Gothic kings, and was subsequently the residence of the exarchs of the Byzantine emperors, from whose title the whole province under their jurisdiction was called the exarchate of Ravenna. The city itself remained in the possession of the Greek emperors until taken by Luitprand, king of the Lombards, in 728, and again after a recapture by Astolphus, one of his successors, in 752. Luitprand destroyed the ancient port of Classis, the site of which at present is about 2 m. distant from the sea. When Pepin had conquered the Lombards he made a present of Ravenna to the pope, and with occasional interruptions it continued to belong to the states of the church until 1860. From 1440 to 1508 it was in the hands of the Venetians, but the league of Cambray placed it again under papal power. It is celebrated for the great victory gained under its walls by the French under Gaston de Foix over the Spaniards and the troops of Pope Julius II., April 11, 1512.

RAVENSCROFT, John Stark, an American clergyman, and bishop of the Protestant Episcopal church, born near Blandford, Prince George co., Va., in 1772, died March 5, 1830. Shortly after his birth his father removed to Scotland, where and in the north of England the son was educated. When 17 years old he returned to Virginia, and with the design of studying law entered William and Mary college. In 1792 he revisited Scotland, and after his return lived for 18 years in Lunenburg co., Va., and while there he never even opened a Bible. In 1810, however, he joined a society called "Republican Methodists;" and in 1816 he was licensed as a lay reader in the Protestant Episcopal church. In 1817 he was ordained as priest, and became minister of St. James parish in Mecklenburg co. In 1823 he was elected bishop of the diocese of North Carolina, and with it took the pastoral charge of the congregation at Raleigh, which he gave up in 1828 and took charge of the church at Williamsborough. In 1829 he was relieved from all parochial care, but died soon after. He published during his lifetime several sermons, which after his death were republished, along with 61 others selected by him for publication, in 2 vols. 8vo., with a memoir of his life.

RAVIGNAN, Gustave Xavier de, a French preacher and author, born in Bayonne, Dec. 1, 1795, died in Paris, Feb. 26, 1858. He sprang from an illustrious family, and after completing his studies at the *lycée Napoléon* at Paris, was offered a place at the emperor's court, which he refused. He studied law until the schools were closed in consequence of political events, after which he went to Bordeaux (1814), espoused the cause of the Bourbons, and on the reappearance of Napoleon joined the army. Having distinguished himself at the battle of Behobie by his efforts to save the life of his commanding officer at the risk of his own, he received the rank of lieutenant of cavalry. At the close of the war he returned to Paris, resigned his commission, and resumed his legal studies. His admission to the bar was soon followed by his appointment as assistant auditor of the supreme court of Paris, and a brilliant career was just opening before him when in 1822 he resolved to devote himself to the church, entering for this purpose the seminary of St. Sulpice at Issy. In the same year he became a member of the society of Jesus. After having taught dogmatic theology for several years to the younger Jesuits, at first in France and afterward in Switzerland, he succeeded the Dominican preacher Father Lacordaire in the pulpit of the cathedral of Notre Dame at Paris in 1837. The sermons or "conferences" which he delivered there during Lent from 1837 to 1846 gave him a great name as a preacher, and many of them have been published. In 1837 he also opened a house of his order at Bordeaux, and was its superior for 5 years, after which he resided permanently in Paris. He took an active part in the struggle between the Jesuits and the university, chiefly on the subject of education, and to defend the society from the attacks of Michelet, Quinet, and others, wrote his little work *De l'existence et de l'institut des Jésuites* (8vo., 1844; 7th ed. enlarged, 1855), which led to an animated controversy. During the latter 10 years of his life he was engaged in a very extensive correspondence with many of the leading men of Europe. He preached on Sundays in the chapel of the Tuileries, and in 1851 visited London and preached in French during the great exhibition. After that he lived chiefly in retirement, his health forbidding a continuance of the active labors in which he had been engaged. Beside a series of articles in a religious journal in defence of the immaculate conception, he published *Conférence prêchée à Toulouse* (8vo., 1845) and *Clément XIII. et Clément XIV.* The last named work is a history of the suppression of the Jesuits, written to counteract the book of the Theatine Father Theiner on the same subject.

RAWDON, Lord. See Hastings, Francis.

RAWLE, William, an American lawyer, born in Philadelphia in 1759, died April 12, 1836. He was educated at the academy of the society of Friends in his native city, studied law in New York, London, and Paris, and commenced practice in Philadelphia in 1783. In 1789 he was elected to the Pennsylvania legislature, and was subsequently appointed U. S. district attorney for that state by President Washington. He was the first president of the Pennsylvania historical society, to whose published collections he made frequent contributions. In 1822 he was chosen chancellor of the associate members of the bar of Philadelphia, which body published several discourses delivered by him. He wrote "A View of the Constitution of the United States" (1829).

RAWLINSON, Sir Henry Creswicke, an English archæologist, born in Chaddington, Oxfordshire, in 1810. He was educated at Ealing in Middlesex, and at the age of 16 entered the military service of the East India company, and served with the troops of the Bombay presidency until 1833, when in common with several English officers he joined the army of the shah of Persia, holding in it the rank of major. In 1835, while stationed at Kermanshah, he began his study of the cuneiform inscriptions, visited Bagdad in 1836, travelled in Luristan and Susiana, went with the Persian army to the frontier, and subsequently returned to Kermanshah. In 1837–'8, while stationed at Teheran, he communicated to the royal Asiatic society of London announcements of his cuneiform discoveries, and published an account of his travels in Susiana in the "Geographical Society's Journal." While at Bagdad in 1839 he wrote for the same journal a paper on Ecbatana, and at the next anniversary meeting obtained for it the gold medal of the society. In the same year he also forwarded a translation of most of the Behistun inscriptions, a part of which were published in Sept. 1846, and the remainder in Dec. 1847. The breaking out of the Afghan war occasioned his recall, and after travelling through Sinde to Candahar and thence to Cabool, where he was associated with Capt. Arthur Conolly in the mission to Khiva, Bokhara, and Kokand, he was transferred to Candahar, in which place he remained as political agent until the end of 1842. In 1843 he went to Bagdad as political resident, and in 1844 was made British consul, and in 1851 consul-general, and was also promoted to the rank of lieutenant-colonel. With the exception of a visit to England in 1850–'51, he resided constantly at Bagdad until 1855, prosecuting diligently his study of the cuneiform characters and of the oriental tongues. He published the processes of his investigations in numerous papers in the "Journal of the Royal Asiatic Society," and many of their results are embodied in notes and essays to the translation of Herodotus made by his brother, the Rev. George Rawlinson, of Oxford. Returning to England, he was appointed a crown director of the East India company in 1856, and created knight commander of the bath. In Jan. 1858 he was elected to parliament from Reigate, but on the extinction of the East India company was appointed a member of the council of India, and in consequence was obliged to give up his seat. In April, 1859, he was made envoy extraordinary and minister plenipotentiary to the court of Persia, and is now residing at Teheran. His present rank in the army is that of major-general. Beside his numerous contributions to scientific periodicals, he has published "Outline of the History of Assyria, as collected from the Inscriptions discovered by A. H. Layard in the Ruins of Nineveh; printed from the Journal of the Asiatic Society" (London, 1852), and "Memorandum on the Publication of the Cuneiform Inscriptions" (1855), and edited a collection of cuneiform inscriptions (folio) from the originals in the British museum.—**George,** an English clergyman, brother of the preceding, was graduated at Oxford, and became a fellow and tutor of Exeter college. He was Bampton lecturer in 1859; his lectures were published, entitled "Historical Evidence for the Truth of Christian Records" (London, 1860). He has also published "Christianity and Heathenism" (1861), and, in connection with Sir H. C. Rawlinson and Sir J. G. Wilkinson, has prepared an annotated edition of Herodotus (4 vols., London, 1858–'60). He is now (1861) engaged on a historical work called "The Five Great Monarchies of the Ancient World, Chaldea, Assyria, Babylonia, Media, and Persia," to form 3 vols. 8vo.

RAY, the name of the plagiostome, chondropterygian, or cartilaginous fishes of the sub-order *raiæ*, popularly called skates. The numerous families are characterized by great flatness and width of the body, the latter arising principally from the extreme expansion of the pectoral fins; the skull is flat, the upper wall generally membranous, and movably articulated, as in sharks, by 2 condyles and an intervening space with the spine; anteriorly the head ends in a tapering cartilage which supports the snout; spout holes and eyes on the dorsal aspect, the latter without lids or with an upper adherent one; on the ventral surface are 5 slit-like gill openings, before the ventrals and under the pectorals; the scapular arch is complete above and below, supporting the long, jointed, cartilaginous rays of the pectorals; between this and the pelvic arch, supporting the ventrals, lie the abdominal viscera, and between it and the narrow skull are the branchial apparatus and the vascular centres. In the torpedos the cellular galvanic batteries occupy the spaces between the skull and the pectorals; and a homologous rudimentary apparatus has been found in the tail of common skates, showing the adherence to a general plan of structure irrespective of function. The tail in some is fleshy and tapering, in others slender and cartilaginous, in others elongated like a whip lash, and in others armed with lancet-shaped spines on the upper surface, forming a very formidable weapon. The gills consist of membranous folds on plane surfaces, and the arterial bulb has from 3 to 5 transverse rows of semilunar valves. The reproductive secreting organs are of a compact and oblong form, the efferent tubes communicating with the ureters and ending in a rudimentary organ in the cloaca; the claspers are present in the males, as appendages to the posterior edge of the anal fin, furrowed toward the end, leading to a blind subcutaneous sac well lubricated with mucus and the secretion of a glandular body; the ovaries are comparatively small, and the ova are larger and fewer than in common fishes, and more as in birds; most of the genera are viviparous, but some of the genus *raia* are oviparous. The claspers are probably something more than organs of prehension; they may be so rotated as to bring an opening in them opposite to the spermatic duct, and may, according to Agassiz ("Proceedings of the Boston Society of Natural History," vol. vi. p. 377, May, 1858), be introduced into the oviducts, and reach the glands there situated for the formation of the egg case. The egg cases of the skate are often seen on our beaches after a storm; they are of a quadrangular form, about two inches by one, of a brown color and leathery consistence, each corner prolonged into a tubular process; they look somewhat like pillow cases, and are often called sailors' purses (being usually found empty) and skates' barrows. The young within the egg has no investing membrane, and the yolk seems to bear no relation in size to that of the embryo; water for the purpose of respiration is admitted and ejected through the corner prolongations, and the young fish escapes through a transverse fissure at one end. The horny egg case may be formed by each oviduct, and is surrounded by a glandular enlargement which secretes its materials; it is formed before the egg descends into it, in the shape of a pocket open above for the reception of the egg, which must be impregnated in the ovary, contrary to the usual order of things, in which the yolk is enclosed before the shell is formed; as the eggs are found to be of different sizes and various degrees of development in the ovary, it is probable that several years are required for their maturity; these peculiarities show the propriety of placing the skates (with the sharks forming the division of selachians of Aristotle and Agassiz) in a class by themselves. The teeth of the rays are generally tubercular, in close quincunx order like a mosaic pavement. Disgusting as is the form of the rays, their flesh is esteemed a delicacy in England and France, though it is rarely eaten in America except by those of European origin; it is tough when first caught, but becomes tender by being kept several days; with us it is most commonly used as bait for lobster pots, or for manure. Of the families of rays, the *pristidæ* and *torpedinidæ* will be described under SAWFISH and TORPEDO respectively; the *cephalopteridæ* have been noticed under DEVIL FISH.—The family *rhinobatidæ* are intermediate between sharks and rays, having the form of body, position of fins, thick fleshy tail, and smallness of pectorals of the former; the anterior part of the body forms a disk by the union of the pectoral fins with the snout, the latter divided from the former by a furrow, whence these have been called beaked rays; the 1st dorsal is over the ventrals; the caudal bilobed, with the upper lobe the larger, and the keel of the sides continued along it; margins of mouth generally undulated, 3 protuberances of the under jaw fitting into corresponding indentations in the upper; nostrils longitudinal near the mouth, with flaps.—In the family *raiidæ* or the typical rays, the snout is more or less pointed, the disk of the body and pectorals usually of a rhombic figure; tail slender, with 2 small dorsals near the end and sometimes a caudal; spout holes near the eyes; mouth curved, with the convexity forward; teeth of males with a central cusp in spawning time; skin either smooth or studded with prickles pointing backward, sometimes with spines on the dorsal ridge and sides of tail. This family includes the genus *raia* (Cuv.), with about 30 species, embracing the best known in America and in Europe, and such as are commonly eaten in the latter. The smooth ray or common skate of the northern coast of America is the *raia lævis* (Mitch.); it is of a uniform light brownish color above, and dingy white below; the female is marked above with blackish spots; it attains a length of from 3 to 5 feet, and a weight of 200 lbs.; it is found from New York to the British provinces; the body is generally smooth, but there are small spines about the orbits, on the anterior edge of the pectorals, and on the tail; the snout is blunt, and the teeth in compact rows, 6-sided and nearly smooth. Its flat form is peculiarly adapted for life on or near the bottom; the usual mode of progression is by a gentle undulating movement of the pectorals, intermediate between flying and swimming; when in pursuit of prey or escaping from its enemies, the motions are rapid. The young are produced twice a year, in spring and in autumn, deposited in thin, horny, nearly quadrangular cases. Its flesh is said by Mr. Perley to be extensively consumed, and the fleshy part of the pectorals to be beautifully white and delicate; it is usually dressed in long thin slips, rolled like ribbon. On the coast of New England, Nova Scotia, and New Brunswick, it is frequently taken, and of large size, by the cod fishers, being generally hooked by its pectorals; it is pulled up like a dead weight to near the surface, unless caught by the mouth or head, and struggles violently on being drawn out. It feeds on fish, crustaceans, and mollusks, and is very voracious; it digs up clams with its powerful spade-like snout, crushing them easily with its rolling flattened teeth. The skin is covered with an abundant tenacious slime, so dirtying their boats that fishermen ordinarily bring them to the surface, beat them over the head, and cut them loose to sink. There are 8 or 9 species in European waters, some attaining a weight of 200 lbs. The sharp-nosed ray (*R. oxyrhyncha*, Linn.) attains a length of 6 feet; this is the favorite species in the French markets. The common skate or ray (*R. batis*, Linn.) is a large species, with a granulated skin above; the color is brown above, cinereous below or grayish white with black specks. Several species are common in the London market, where the females are known as maids.—In the family *trygonidæ* or sting rays the tail is slender, often whip-like, naked or bearing one or more barbed spines; no caudal fin; pectorals large, uniting in front of the head; spout holes large and close behind the eyes; teeth small, transversely elliptical, and ridged; skin either smooth or prickly, but without prickles on the pectorals. The genus *trygon* (Adans.) is the most numerous in species. The American whip sting ray (*T. hastatus*, De Kay) occurs on the coast of the middle states, in Long Island sound, and sometimes on the coast of Massachusetts; it is olive brown above, and white below; it attains a length of 5 to 8 feet, including the tail. It is not uncommon on the shores of New Jersey, where it is caught both by hook and seine, varying in size from a breakfast plate to a width of 4 feet and a tail of 5; the fishermen always cut off the tail at once, to prevent wounds from its spines, which, being serrated, produce extensive lacerations accompanied by severe inflammation. The principal use made of this species, and indeed of all the rays in this country, is to extract the oil from the liver, which, with that from this organ in sharks, is employed for various domestic and medicinal purposes. The European sting ray (*T. pastinaca*, Bonap.) is common in the Mediterranean and on the southern Atlantic coast; it was well known to the ancients, who thought it capable of inflicting poisoned wounds; it twists its long tail around its prey or its enemies, causing very severe lacerated wounds; its flesh is not eatable. The spines of some of the species of this genus are employed by savages as arrow and spear heads.—In the family *myliobatidæ* or eagle rays, the head is more elevated than in the other families, projecting as far as the gills, without fin rays on its sides, but with a kind of cephalic fin in front of the skull making the point of the disk; the pectorals are very large and wing-like; the tail is long and slender, with a small dorsal and strong spine; the mouth is transverse, with the dental plates reaching far back into the cavity of the mouth; the teeth are like a mosaic pavement, large and even, in several rows forming a convex surface; the eyes and spout holes are on the sides of the head, and a broad ridge runs between the two; the interrupted pectorals on the sides of the head are a family character. In the genus *myliobatis* (Cuv.) the nasal membrane is square, and the pectorals end in an angular projection; the teeth form long hexagonal plates in the middle, with 2 or 3 short or equal rows on the sides. The *M. acuta* (Ayres) is found on the Massachusetts coast and in Long Island sound and attains a length of about 4 feet; the body is smooth and reddish brown above, whitish below; tail very slender and armed with spines. The eagle ray of the Mediterranean (*M. aquila*, Risso) grows to a large size; the wounds made by its spines are so dreaded by the fishermen that the tail is cut off as soon as possible. Several species are found in the seas of the warm parts of the globe. In *rhinoptera* (Kuhl) the nasal membrane is notched; the central teeth are the largest, the 3 lateral rows growing smaller and smaller externally. In *aëtobatis* (Müll.) the nasal membrane is lobed, which would embrace many species of *rhinoptera* as usually defined, and the pectorals are rounded; the teeth form a single row of simple arched plates, without lateral rows. In *zygobatis* (Ag.) the nasal lobes and the pectorals are as in the preceding genus; the central rows of teeth are much the longest, the 1st lateral about half as large, and the 2 external very much smaller. In *goniobatis* (Ag.) the palate is broadest behind, and the plates are obtusely angular, with their rounded edges forward.—There is hardly a family of fishes in the classification of which more confusion reigns than that of the rays; naturalists see them only in rare instances, and almost always single specimens at a time; there can be little doubt that the two sexes of the same species have in some instances been made into distinct species. Even our most common rays are very imperfectly known, and the genus *raia* embraces many species which are not congeners.

RAY, a N. W. co. of Mo., bordered S. by the Missouri river; area, about 570 sq. m.; pop. in 1860, 14,091, of whom 2,047 were slaves. It has an undulating surface, covered by forests and prairies, and a generally fertile soil. The productions in 1850 were 605,020 bushels of Indian corn, 46,003 of wheat, 138,641 of oats, 216,000 lbs. of tobacco, 27,277 of wool, 185,137 of butter, and 431 tons of hemp. There were 8 saw mills, 2 tanneries, 8 churches, and 500 pupils in public schools. Capital, Richmond.

RAY, Isaac, M.D., an American physician, born in Beverly, Mass., in Jan. 1807. He was graduated at the Harvard medical school, Boston, and commenced the practice of medicine in Portland, Me., in 1827. In 1829 he removed to Eastport, Me., where he studied the science and literature of insanity, and prepared his treatise on the "Medical Jurisprudence of Insanity" (1838). In 1841 he was appointed superintendent of the state insane hospital at Augusta, where he remained till 1845, when he was chosen superintendent of the newly established Butler hospital for the insane, at Providence, R. I. He is still the head of that institution. Dr. Ray has been a frequent contributor to medical and literary periodicals.

RAY, John (or Wray, as he at one time spelled his name), an English naturalist, born near Braintree, Essex, in 1627, died in 1704. He was the son of a blacksmith, and was graduated at Trinity college, Cambridge, in which he obtained a fellowship in 1649, the professorship of Greek in 1650, and a mathematical tutorship in 1652. His health being impaired, he travelled over the greater part of England, Wales, and Scotland, studying their botany and zoology. At the restoration he took orders, but never held any church preferment, and two years later resigned his fellowship, as he could not conscientiously subscribe to the act of uniformity. After this he resided chiefly with one of his former pupils, Francis Willughby, at Middleton hall, in Warwickshire, devoted to the study of natural history. From 1663 to 1666 he travelled with Mr. Willughby on the continent, and published an account of this tour in 1673. In 1667 he was elected a fellow of the royal society. Among his most important works are: *Catalogus Plantarum Angliæ* (1670), the foundation of all English floras; *Methodus Plantarum Nova* (1682), in which he proposed a new method of classification, which, as subsequently altered and amended by himself, formed the basis of the method of Jussieu; and *Historia Plantarum* (3 vols., 1686-1704), his largest botanical work. He edited Willughby's works on the animal kingdom, and published several of his own, which were regarded by Cuvier as "the foundation of modern zoology." Of his other writings, his "Collection of English Proverbs" (1671) has passed through many editions, and was reprinted with additions by H. G. Bohn (London, 1850).

RAYMOND, Henry Jarvis, an American journalist, founder of the "New York Times," born in Lima, Livingston co., N. Y., Jan. 24, 1820. His father was the proprietor of a small farm, in the labors of which the son was early employed. While still young he entered the academy of Lima, and in the winter of 1835-'6 taught a district school. He was graduated at the university of Vermont in 1840, and repairing to New York, studied law for a year in the office of Mr. Edward W. Marsh, maintaining himself by teaching the classics in a young ladies' seminary, and by contributions to the "New Yorker," a literary journal. When, in April, 1841, the "New York Tribune" was established, Mr. Raymond became connected with it as assistant editor, and in that capacity greatly distinguished himself by extraordinary success in reporting, an art then comparatively little practised in America. In 1843 he accepted an offer from Mr. James Watson Webb of a position on the staff of the "New York Courier and Enquirer," which he relinquished in 1851, in consequence of a political disagreement with Mr. Webb. He had also, some 4 years before, formed a literary connection with the publishing house of Harper and brothers, which continued 10 years. During this period he had a prolonged controversy with Mr. Horace Greeley, in the columns of their respective journals, upon the principles of socialism, especially as taught by Fourier, Mr. Raymond attacking and Mr. Greeley defending them; the successive articles on each side attracted much attention, and were afterward published in a pamphlet. In 1849 Mr. Raymond was elected by the whigs of his district to the state legislature, where he soon became prominent as a debater and a practical legislator. He was reëlected in 1850, when he was chosen speaker of the assembly, and during this session manifested special interest in the common school system and the canal policy of the state. After its adjournment he sailed for Europe for the benefit of his health, returning in August, and publishing a little later (Sept. 18, 1851) the first number of the "New York Times" daily journal. In 1852, in the capacity of substitute for a regular delegate to the whig national convention at Baltimore, he addressed that body at length, in spite of a very violent and stormy opposition, in exposition of northern sentiment. In 1854, under nominations by the whig, anti-Nebraska, and temperance conventions, he was elected lieutenant-governor of the state by a large majority over two opponents. He took an active share in the organization of the republican party, consequent on the repeal of the Missouri compromise, and drew up the "Address to the People" promulgated by its first national convention, held at Pittsburg in Feb. 1856; and during the succeeding presidential canvass he made numerous public speeches in support of its candidate, Mr. Fremont. Since the close of his term as lieutenant-governor, Dec. 31, 1857, Mr. Raymond has held no office, having declined in that year to be a candidate for governor of the state. In the presidential canvass of 1860 he again took a prominent stand, both in his journal and in public addresses, in favor of the republican candidate, Mr. Lincoln; and by the same modes he has in 1861 warmly supported the war against the seceding states.

RAYNAL, Guillaume Thomas François, known as the abbé, a French philosopher and author, born at St. Geniez, Guienne, in March, 1711, died in Paris, March 6, 1796. He was educated at a college of the Jesuits, became a priest, and for some time taught theology and preached in his native province. Ambition and restlessness of temper induced him in 1747 to repair to Paris, where he became an assistant clergyman at the church of St. Sulpice. His provincial accent was an insuperable obstacle to his success in the metropolitan pulpit, and, disappointed in his anticipations, he soon gave up the ministry, associated with the "philosophers," and became director of the *Mercure de France*, then a very successful periodical. He published various historical works, and, with the assistance of Diderot and others, prepared anonymously a *Histoire philosophique et politique des établissements et du commerce des Européens dans les deux Indes* (4 vols. 8vo., 1770), which was favorably received and for about 10 years circulated freely without being noticed as objectionable. In a second edition, however, he introduced attacks upon religion and government so openly that the work was interdicted on Dec. 19, 1779; and when the edition appeared under his name at Geneva (10 vols. 8vo. and 5 vols. 4to. with an atlas, 1780), a warrant was issued for his arrest, which he avoided by leaving France; and the parliament ordered his book to be burned by the hand of the executioner (May 25, 1781). In the same year he published his *Tableau et révolutions des colonies Anglaises dans l'Amérique septentrionale* (2 vols. 12mo.), which was immediately translated into English. Its blunders were at once pointed out in a pamphlet by Thomas Paine. For several years Raynal wandered in foreign countries, and was finally permitted to return home in 1788. He was elected a deputy to the states-general by the city of Marseilles, but declined the honor on account of his age. His friend Malouet, who was chosen in his place, succeeded in 1790 in having the sentence of the parliament against his *Histoire philosophique* reversed. The next year Raynal addressed to the president of the constituent assembly an eloquent letter recanting his former principles, and insisting upon the necessity of investing the king with more ample powers than were left to him by the new constitution. His chief work is now fallen into oblivion. The English translation by Justamond was published in 1776 (3 vols., London) and in 1783 (8 vols.).

RAYNOUARD, François Juste Marie, a French dramatic and miscellaneous author, born in Brignolles, Provence, Sept. 18, 1761, died at Passy, near Paris, Oct. 27, 1836. He was by profession a lawyer. Elected an assistant deputy to the convention, he sided with the Girondists, and on their fall was thrown into prison, from which he was released by the revolution of Thermidor. In 1803 he obtained a prize at the French academy for a poem entitled *La vertu nécessaire dans les républiques*, and in the following year another for *Socrate dans le temple d'Aglaure.* In 1805 his 5-act tragedy *Les templiers* created an unparalleled sensation; the piece was recommended by the institute for one of the decennial prizes, but Napoleon, being displeased with the author's *États de Blois*, played at St. Cloud in 1810, disregarded their advice. The academy meanwhile elected him a member in 1807. In 1806 he had been elected by his native department a deputy to the legislative body, where in 1813 he was chosen one of the committee of 5 to whom were referred some demands made by the emperor. The report, mostly drawn up by Raynouard, though presented by Lainé, severely condemned Napoleon's warlike policy, and, instead of recommending subsidies, insisted upon the grant of enlarged political liberties. Napoleon caused the report to be suppressed, and immediately adjourned the chambers. During the Hundred Days Raynouard was offered the title of councillor of the university and the post of minister of justice, both of which he declined. He now applied himself to the study of the Provençal language, and published *Choix des poésies originales des troubadours* (6 vols. 8vo., Paris, 1816–'24). His *Lexique Roman, ou Dictionnaire de la langue des troubadours, comparée aux autres langues de l'Europe Latine*, was posthumously published (6 vols. 8vo., 1838–'44). He was elected perpetual secretary of the French academy in 1817.

RAZOR. See Cutlery.

RAZOR FISH (*xyrichthys*, Val.), an acanthopterygian genus belonging to the family of *cyclolabridæ*. The body is compressed and covered with large scales, the lateral line interrupted; the profile is almost vertical, the forehead trenchant, and the eyes high up; the sharpness of the head is not owing to the interparietal crest as in *coryphæna* (the dolphin of sailors), but to the ethmoid and intermaxillaries growing directly downward, the lower jaw being horizontal and of ordinary length; the cheeks are scaleless, and the snout smooth and blunt; the dorsal is long and of uniform height; the teeth are in one row, conical, largest in the middle; the palate and tongue are smooth, but the pharynx is furnished with small and pavement-like teeth; the intestinal tube is simple, without stomachal dilatation and pancreatic cæca; the air bladder is large, pointed in front. The type of the genus is the razor fish of the Mediterranean (*X. cultratus*, Val.); it is about 8 inches long, of a reddish color, variously striped with bluish; its flesh is highly esteemed as a delicate food; it lives solitary, on sandy bottoms near the shores, feeding on such fish and mollusks as its very small mouth enables it to swallow.

About a dozen other species, of the same size, are found in the East and West Indies, among the Pacific islands, and on the coast of South America, where their flesh is eaten; in some the 3 anterior rays of the dorsal are detached and placed far forward, forming 2 dorsals.

RAZOR SHELL (*solen*, Linn.), the type of the lamellibranchiate family of *solenidæ*. The genus is characterized by 2 adductor muscles, the mantle open anteriorly and produced into 2 short united siphons, the branchiæ attached to the lower; the foot is long and club-shaped; the shells are elongated, equivalve, and gaping at both ends; the hinge has 2 or 3 compressed teeth in each valve, and is nearly terminal; the ligament is long and external. The common razor shell of our coast is the *S. ensis* (Linn.), of a scabbard shape, about 6 inches long and one inch high, with rounded ends, white within and covered outside by a glossy yellowish or brownish green epidermis. It is found on sandy beaches near low water mark, where it burrows beneath the surface, whence it is sometimes displaced by storms; it descends into the sand with astonishing rapidity; the animal is cylindrical, longer than the shell, and is often used as food under the names of long clam, knife handle, and razor fish. The *S. siliqua* and *S. curtus* of Europe have similar habits, sinking vertically in the sand, foot downward; their burrows are sometimes 2 feet deep, and they ascend and descend in them very quickly by widening or narrowing the foot. They are used as food, and as bait for cod and haddock; their burrows may be known by small orifices like keyholes, into which the fishermen put a little salt; this so irritates the tubes that the animal ascends near the surface, and is dragged out by an iron hook; when taken from their holes, they will, if possible, again rapidly bury themselves. They are found in almost all known seas.

RAZZI, Giovanni Antonio, called Il Sodoma, an Italian painter, born in Vercelli, Piedmont, in 1479, died in 1554. He formed his style on that of Leonardo da Vinci, and in the early part of the 16th century was employed by Pope Julius II. to execute a series of works in the Vatican, which were afterward in part obliterated to make room for the frescoes of Raphael.

REACH, Angus Bethune, a British journalist and author, born in Inverness, Scotland, Jan. 23, 1821, died Nov. 25, 1856. He became about 1850 a reporter on the staff of the London "Morning Chronicle," and was afterward for several years a fertile writer for that journal. He composed much for the stage and for the magazines, and published several works, among which are "Claret and Olives: from the Garonne and the Rhone," an account of a journey in the south of France, and two romances, "Clement Lorimer" and "Leonard Lindsay," a story of a buccaneer.

READ, George, one of the signers of the declaration of independence, born in Cecil co., Md., in 1734, died in 1798. He was the son of a planter, studied law at Philadelphia, was admitted to the bar at the age of 19, commenced the practice of his profession at New Castle, Del., and in 1763 was appointed attorney-general for the 3 lower counties on the Delaware, the designation by which the present state of Delaware was then known. In 1774 he was elected to congress, of which he continued to be a member, with a brief interval, till near the close of the revolution. When the question of independence was first agitated, Mr. Read opposed it as premature, but was afterward among its most zealous supporters. In 1776 he was president of the convention that formed the first constitution of Delaware, under which he was chosen vice-president, and served for a short time as president during the captivity of the regular incumbent. In 1782 he was made judge of the U. S. court of appeals in admiralty cases. He represented Delaware in the convention that framed the constitution of the United States, and was the first senator chosen under it for that state. He retained his seat in the senate till, in 1793, he was made chief justice of Delaware.

READ, Nathan, an American inventor, born at Warren, Worcester co., Mass., July 2, 1759, died near Belfast, Me., Jan. 20, 1849. He was graduated at Harvard college in 1781, and was tutor there for 4 years. In 1796 he established, with others, the Salem iron foundery, and invented a machine, patented in Jan. 1798, for cutting and heading nails at one operation. In 1800 he became a member of congress. In 1807 he removed to Belfast, Me., and for many years was chief justice in the court of Hancock co. In 1788 Mr. Read's attention was directed toward adapting the steam engine for propelling boats and carriages, by devising some lighter and more compact machinery than Fitch was then experimenting with. Pursuing substantially the same course which Fulton afterward followed, he first invented, as a substitute for the great working beam, the cross head, running in guides, with a connecting rod to communicate the motion, which was adopted by Fulton in his second boat, the Car of Neptune. The "new invented cylinder," as he calls it, to which this "working frame" was attached, was a double-acting cylinder, like Watt's last improvement, with which Read does not seem to have been acquainted. To render the boiler more portable, Read invented the multitubular form, which was patented with the cylinder, chain wheel, &c., Aug. 26, 1791. This boiler was either horizontal or upright, cylindrical, and contained the furnace within itself. A double cylinder formed a water jacket, connecting with a water and steam chamber above, and a narrow water chamber below. A number of small straight tubes parallel to the axis of the boiler, and about ⅔ its length, also connected these chambers; while the central tubes, being closed at the bottom, and not reaching quite to the bottom of the boiler, left a space for the fire, which passed around instead of through the tubes. The smoke pipe passed through a reservoir above the boiler, partly heating the water before it entered the boiler. The rise of the heated water would create a constant current through the tubes. Although this form of boiler is perhaps inferior to those with fire tubes, in cases where, as in locomotives, a very strong draught is attainable, it is yet coming into extensive use in marine engines, being recommended by its small consumption of fuel and greater freedom from incrustration. Read also invented another form of boiler, in which the fire passed through small spiral tubes on the principle of the present locomotive boiler, an arrangement which, he remarks, would have the advantage of consuming the smoke. Beside these, he had several other forms, with numerous apartments, to which the water was to be gradually admitted, as fast as evaporated. As a means of communicating motion to his steamboat, his first plan was to use paddle wheels; but finding that these had been used before, he substituted a chain wheel of his own invention. He regarded the former however as the best, and to try their power he caused a small boat to be fitted with paddle wheels and cranks, with which he made experiments on Porter's river at Danvers, Mass., in 1789. Read also planned a steam carriage, which, with his tubular boiler, he asserted could be made to move at the rate of 5 miles an hour with a load of 50 tons. He also invented a method of equalizing the action of wind mills, by accumulating the force of the wind by winding up a weight; a plan of using the force of the tide by means of reservoirs alternately filled and emptied in such a way as to produce a constant stream; different forms of pumping engines and threshing machines; and a plan for using the expansion and contraction of metals, multiplied by levers, for winding up clocks and other purposes.

READ, Thomas Buchanan, an American painter and poet, born in Chester co., Penn., March 12, 1822. At the age of 17 he went to Cincinnati, and entered a sculptor's studio, but soon after devoted himself to painting. In 1841 he removed to New York, and a little later to Boston, where he continued the study and practice of his art, mostly in portrait painting. He took up his residence in Philadelphia in 1846, visited Europe in 1850, returned to Cincinnati, and since 1853 has resided in Florence. His first volume of poems was published at Boston in 1847, and was followed by a collection of "Lays and Ballads" (Philadelphia, 1848). In the same year he edited a collection of "Specimens of the Female Poets of America," and in 1853 published an illustrated collection of his poems. His first long poem, "The New Pastoral," was published in 1855, and "The House by the Sea" in 1856. A new edition of his poetical works in a collected form was published in 1860 (2 vols., Boston). Of his pictures, the "Lost Pleiad" and the "Water Sprite" are perhaps best known.

READE, Charles, an English novelist. He was educated at Magdalen college, Oxford, and first became a popular favorite by his novel of "Peg Woffington," which immediately brought him into notice. Following up this success, he has produced a number of works of fiction, among which are "Christie Johnstone;" "White Lies" (1855); "Never Too Late to Mend" (3 vols., 1856); "A Good Fight and other Tales;" and "Love me Little, Love me Long." His last work is entitled "The Eighth Commandment" (1860), and is an attack on the English system of dramatic copyright. Mr. Reade has dramatized several of his novels, and is a frequent writer for the stage and for magazines.

READING, the capital of Berks co., Penn., on the left bank of the Schuylkill, and on the Philadelphia, Reading, and Pottsville railroad, 58 m. N. W. from Philadelphia, and 52 m. E. from Harrisburg; pop. in 1860, 23,165. It is very pleasantly situated on an elevated and ascending plain, backed on the E. by Penn's Mount, and on the S. by the Neversink mountain, from both of which flow streams of pure water, with which the city is abundantly supplied. It is regularly laid out, well built, and kept neat and cleanly. The streets cross each other at right angles, and in the centre is a square. The court house is a very handsome edifice, with a fine portico, and there are several other public offices. Reading contains also a gaol, 2 banks, 8 public libraries, a number of newspapers, 2 market houses, and about 20 churches, of which the German Lutheran and the German Reformed are the most conspicuous. There are various manufactories, including 3 anthracite blast furnaces, one of which is first class in style and capacity, 2 large rolling mills, 4 founderies, a nail factory, cotton factory, woollen mill, steam saw mill, and 2 flour mills. It has an active trade by means both of the railroad and of the Schuylkill and the union canals, the first of which gives it communication with the coal regions to the N., the other with the rich agricultural districts to the W.

READING, the county town of Berkshire, England, situated on the river Kennet, near its junction with the Thames, 36 m. by railroad W. by S. from London; pop. in 1851, 21,456. Silk, velvets, iron, &c., are manufactured. Reading returns two members to parliament.

REALGAR. See Arsenic, vol. ii. p. 165.

REALISM. See Nominalism.

REALTY (Lat. *res*, a thing), in law, rights or property in lands, tenements, and hereditaments. The common law of real property is distinctively and almost entirely English, being founded on the rules and customs which in the feudal period governed the tenure of lands. It is the theory of the English law, that no occupant of lands, not even a freeholder, has absolute ownership of them. He has only an estate. The king is lord paramount, and all the land in the realm is holden mediately or immediately of him. The chief estates in lands of the present time originated no doubt in the various forms of feudal tenure. Life feuds were probably earlier than feuds of inheritance; for as feuds were granted in consideration of a return of military services, and as this consideration was to be furnished by a certain individual whose already known valor or fidelity induced the gift, lands were without doubt primarily limited to the first donee; that is to say, they could neither be aliened by him to a stranger nor transmitted to his heirs. As the lords however became strong in their possessions, or when the times were more secure, it became safe and possible to grant estates of inheritance in feuds; namely, to the first taker and certain of his heirs or to his heirs in general. From these modes of tenure came the modern estates respectively, for life, in tail, and in fee. Each of these is a freehold and a real interest, but no estate less than one for life (and a lease to A for 1,000 years is, in the contemplation of the law, a smaller interest than a grant for the term of his life) is a freehold or an estate in realty. But beside lands, things real, as the tautological phrase of the law is, comprise also tenements and hereditaments; and these are embraced in this term, because they possess some of the characteristic qualities of lands, as they may be holden on tenure or are inheritable. These terms may include things incorporate. Land includes only tangible or corporeal property. It applies not only to the ground or soil, but to every thing which is attached to it naturally, as trees, stones, or herbage, or by art, as houses or other structures. Growing timber, therefore, and standing grass or grain, so long as they are rooted in and supported by the soil, are parts of the realty, though they become personalty immediately on severance. Yet contracts for the sale of things annexed like timber to the land, in prospect of their immediate separation, or for the sale of fruits of the earth already ripe, but not yet gathered, are not contracts for any interest in land, and so are not within that clause of the statute of frauds which requires that a contract for the sale of an interest in lands should be in writing. (See FRAUDS, STATUTE OF.) The criterion of realty or personalty in these cases is, whether the things sold are dependent for any part of their value on the land, or whether, in other words, the growing surface is to contribute any thing to their value before the things are severed. And it is well established that corn or any other annual product of the soil, if ripe and fit to be gathered, is personal property, and may be attached, as such, while standing in the field, and sold on execution. A permanent building erected on one's land becomes his property, even though the materials for it were wrongfully taken from another. But a building erected on another's land, by his permission, may remain the personal property of the builder. So temporary structures like bathing and fish houses, as they are not substantially fixed to the soil, may be personal property.—Things which have been incorporated with or firmly fixed to the realty, and cannot be removed without injury to it, or even those things which, though not so firmly fixed, have yet been attached and so adapted to the building or land as to be essential to its value and use, regarding the purposes for which it is employed, also become a part of the realty. (See FIXTURE.) —Beside the incidents and elements of land which we have already mentioned, and which are examples of corporeal hereditament, there may be also incorporeal hereditaments, that is, rights annexed to and issuing out of lands, as rights of common and of way, easements, and rents. These rank next in dignity and extent to lands. Rights of common are not much known in the United States. They are rights which one has in the lands of another to pasture his cattle, to take fuel for the use of his family, or timber for repairing his implements of husbandry. A right of way is the right of passage over another man's ground. It may be founded in an actual grant by the owner of the soil, or may be claimed by prescription, which supposes a grant, or it may arise immediately from necessity; as where one sells a lot surrounded by other land of his, here, as a right of passage is necessary to the enjoyment of the lot granted, the grantor is conclusively presumed to have granted it to the purchaser. If the way thus granted and ordinarily used become impassable, it seems just that the purchaser shall have the right, founded on the same presumption, of passing over the adjacent lands of the grantor. Not so, however, if the way be a private one, lying in actual grant, for here the grantor presumptively bound himself to repair. The right of the public in the highway is, ordinarily, only an easement. The fee in the soil belongs to the abuttors, and the complete use of the ground returns to them whenever it becomes discharged of the easement. The road bed of railways is generally subject to the same rules. The right of soil in land bounded by navigable rivers where the tide ebbs and flows, belongs to the owner of the land as far as low water mark. The right to navigate such waters belongs, in all states of the tide, to the public. Grants upon streams above the flow of the tide convey not only the banks but the beds of the streams and the islands in them to the middle line of the water, or *ad filum medium aquæ*. But the right of the grantee is qualified by the right of the public to use the stream as a highway if it be navigable.—An easement is well defined to be a liberty, privilege, or advantage in land, without profit, existing distinct from an ownership of the soil. It is a real interest, is within the statute of frauds, and so can be created only by deed. It differs materially in these and the like respects from license. (See LICENSE.) Among the more *common* forms of easement may be mentioned that *of support*, where the owner of a house allows his neighbor to rest timbers on the walls of his house; the easement of drip, by which one is bound to allow water to fall from his neighbor's house upon his land; rights of way or of drainage which give to their owners, respectively, the privilege of passage or of conducting water over the estate of another. Important rights are those which vest, in respect to running streams, in the proprietors of lands abutting thereon. Every owner of such lands is entitled to the use of the water as it usually flows. His neighbor higher up the stream cannot unduly obstruct the water, nor direct it altogether from its usual channel. He is bound, for the benefit of all proprietors below him, so to use the stream that its natural flow shall be unobstructed, and the enjoyment of it be undiminished.—An exclusive and uninterrupted enjoyment of any easement, in any particular way, for 20 years, or for any less period which by positive statute makes the period of limitation, founds an adverse interest sufficient to raise a presumption of title. Rent is a yearly return out of the profits or value of land in consideration of its use. (See LEASE.)

REAPING MACHINES. See MOWING AND REAPING MACHINES.

RÉAUMUR, RENÉ ANTOINE FERCHAULT DE, a French natural philosopher, born in Rochelle in 1683, died Oct. 18, 1757. He was educated at the Jesuit college in his native town, and studied law at Bourges; but repairing to Paris in 1703, he gained distinction by his philosophical researches, and in 1708 was admitted to the academy of sciences. He contributed in establishing in France or improving various manufactures, and in his treatise, *L'art de convertir le fer forgé en acier, et l'art d'adoucir le fer fondu* (1722), first made known the process of manufacturing steel. He received for his discovery a pension of 12,000 livres, which he applied to the encouragement of that branch of industry. He invented a process for tinning iron, and made experiments with less success in the manufacture of porcelain; an opaque white glass which he made is known as "Réaumur's porcelain." He also discovered the means of preserving eggs, and was the first in France to make successful experiments in artificial incubation. In 1731 he invented the thermometer which is called after him, and is still used in France; taking as the extremes the freezing and boiling points of water, and the former being zero, he divided the interval into 80 equal parts or degrees. He investigated many curious topics in natural history, especially the mode of formation and growth of the scales of fishes, the development of the shells of testaceous animals, and the reproduction of the claws of lobsters and crabs. He ascertained the nature of the singular substance that gives brilliancy to the scales of fishes, and discovered a species of mollusk that furnishes a purple dye nearly equal to that used by the ancients. His most thorough investigations were in the department of entomology, to which he devoted several years. He left *Mémoires pour servir à l'histoire naturelle des insectes* (6 vols. 4to., 1734–'42), besides a variety of papers in the transactions of the academy of sciences.

REBECK, an Arabic word signifying an instrument of the violin kind, which originally had but two strings and was played with a bow. It was introduced by the Arabs into Spain, where a third string was added, and was a favorite at rural festivals. Milton speaks of the "jocund rebeck."

REBOLLEDO, BERNARDINO, count of, a Spanish soldier and author, born in León, 1597, died in 1676. He was of noble family, and at the age of 14 embraced the profession of arms, serving in Italy and against the Turks and the powers of Barbary. He afterward took part in the 30 years' war, was created by Ferdinand II. a count of the Germanic empire, and received the government of the Lower Palatinate. In 1647 he was made by Philip IV. ambassador to the court of Denmark, and from 1662 till his death was minister of state at Madrid. He wrote *Selvas militares y politicas*, poems on the arts of war and civil government (Copenhagen, 1652); *Ocios* ("Leisure Hours," 16mo., Antwerp, 1660); *La constancia victoriosa y Trinos de Jeremias* (4to., Copenhagen, 1665), a paraphrase of the book of Job and the Lamentations of Jeremiah; and *Selvas Dánicas* (4to., 1665), a compendium of the history and geography of Denmark. The best edition of his works is that of Madrid (3 vols. 8vo., 1778).

REBOUL, JEAN, a French poet, born in Nîmes, Jan. 23, 1796. He was the son of a locksmith, and to support his mother, who had been left a widow with 4 young children, established himself as a baker. He composed songs circulated among his friends, but was totally unknown to the public until 1828, when a few lines of his, entitled *L'ange et l'enfant*, addressed to a mother upon the death of her child, appeared in the *Quotidienne* newspaper. In 1836, under the title of *Poésies*, he printed a small volume of poems which was received with great favor, and in 1840 a biblical poem, *Le dernier jour*. He has written a few tragedies, one of which, *Le martyre de Vivia*, was performed in 1850 without particular success. In 1857 he published a new volume of poems, *Les traditionnelles*. In 1848 he was elected to the constituent assembly by the department of Gard, but gained no political distinction.

RÉCAMIER, JEANNE FRANÇOISE JULIE ADELAÏDE, a celebrated French woman, born in Lyons, Dec. 3, 1777, died in Paris, May 11, 1849. She was the daughter of a post office contractor named Bernard, and in April, 1793, married a rich banker of Paris many years older than herself, and by the brilliancy of her conversation and the charm of her person and her manners made his residence a great place of resort for men of education and genius. Under the rule of the directory and during the consulate and empire her house was constantly frequented by distinguished personages, among whom were Lucien Bonaparte, Moreau, Bernane, La Harpe, Benjamin Constant, and Ba- l.; but as the society there took on a form of position to the government, she was obliged Napoleon to leave Paris. She resided for me time in Lyons, then went to Italy, and did reënter France until after the fall of Na- leon, when she returned to Paris and re- ened her saloons. In consequence of a re- rse of fortune, she retired in 1819 to the bbaye-aux-Bois near Paris, but her house nev- theless continued to be the resort of eminent en, among whom was Châteaubriand, who as her devoted admirer. Through her con- ction with that literary circle which regard- Mme. de Staël as its chief, she exercised, though herself producing nothing, a consid- able influence upon French literature. Mme. écamier was considered one of the most beau- ful women of her day. *Souvenirs et correspon- ance tirés des papiers de Mme. Récamier* have en published (2 vols. 8vo., Paris, 1860).

RECIFE. See PERNAMBUCO.

RECITATIVE (Lat. *recito*, to recite), called the Italians *musica parlante*, speaking music, species of artificial declamation adapted to usical notes, and forming a medium between dinary recitation or speaking, which it nearly sembles, and measured air or song. It was st introduced at Rome by Emilio del Cava- ere in 1600, and is now a recognized and in- ed an essential form of vocal composition in e grand Italian opera, oratorios, and canta- s, serving to express some action or pas- on, to relate a story, or to connect scenes and uations, without injuring the effect of the rformance by resorting to spoken words. lthough written in common time, the recita- ve may be delivered by the singer according his fancy, subject of course to the laws of osody, the lengths of the notes as given by e composer being mere approximations. The companiment generally consists of a few oc- sional chords struck by the pianoforte to in- cate the harmony, although sometimes the olonecellos take the chords in *arpeggio*. hen the recitative is interrupted by inter- ated passages performed by the orchestra, is said to be *obbligato*.

RECKE, ELISABETH CHARLOTTE CONSTANTIA n DER, a German authoress, born in Courland, ay 20, 1754, died in Dresden, April 13, 1833. he was the daughter of the count of Medem, nd in 1771 contracted a marriage with Von er Recke, which turned out unhappily, and 7 ears afterward separated from him. This cir- mstance, along with the death of her daugh- er in 1777, and of her brother in 1778, gave to er religious feelings, naturally strong, a mys- cal direction. When Cagliostro came to Mitau Courland, where she was then residing, she ave implicit belief to his claim of the pos- bility of holding communion with the spirits f the dead. In 1784, on a journey to Carls- ad, she became acquainted with Spalding, aller, Zöllner, Nicolai, Bürger, the brothers tolberg, and others, and through association with them was freed from some of her mystical ideas. Upon this she wrote "The Unmasked Cagliostro" (Berlin, 1787), which was translated into Russian by order of the empress Catharine, on whose invitation she visited St. Petersburg in 1795. She left various works, principally religious. Her *Reise nach Italien* (4 vols., Berlin, 1815 *et seq.*) is the description of a journey to that country made in 1804 in company with her friend Tiedge, who afterward wrote her life.

RECOGNIZANCE (law Fr. *reconisaunce*; law Lat. *recognitio*), an obligation of record entered into before a *court of record* or magistrate duly authorized to take it, with condition to perform some specified act; as to appear at the assizes or criminal court, to keep the peace, to pay a debt, or some other thing of a like description, upon the performance of which condition the obligation is to become null and void. The state or person in whose favor or to whom the recognizance is made is called the cognizee, and the person who enters into it the cognizor. The word *recognizance* is given to this kind of obligation, because, generally, the form of it is this: the clerk or other proper officer says to the cognizor: "You acknowledge yourself bound to," &c.; to which the cognizor assents; and it is then made matter of record.—Recognizances are of several kinds and descriptions, and are used for various purposes both civil and criminal. Of the former kind was a recognizance of debt at common law, in the nature of a deed to charge or incumber lands. This was very similar in form and effect to an ordinary bond, the main distinction being that while a bond is the creation of a fresh debt or obligation, a recognizance was the acknowledgment of a debt already existing upon record. It was certified to or taken by the officer of some court, and witnessed only by the record of such court, instead of having the cognizor's seal affixed to it. It was not strictly a deed, though in effect it was of greater force and obligation, and was allowed a priority of payment, and bound the lands of the cognizor from the time of its enrolment on record. It operated as a lien upon all the lands which the cognizor possessed at the time he acknowledged it, and also upon all those which he afterward acquired, so that no alienation of them made by him while his recognizance remained in force would defeat the claim of the cognizee or prevent his extending such lands. Recognizances for debt may still be taken in this country under statutory provisions, but they operate merely as evidences of debt in the nature of a judgment, upon which execution may issue, and do not generally create a lien upon the cognizor's land or other property.—There were also, at common law, two other recognizances of a private sort, said to be in the nature of a statute staple and a statute merchant. The undertaking of special bail in a civil action, of which the bail piece (a slip of parchment so called, on which it was transmitted to court) was a memorandum, was a recognizance entered into by the cognizors before the court or judge for a sum equal (or in some cases double) to that which the plaintiff had sworn to, by which they undertook that if the defendant was condemned in the action he should pay the costs and condemnation, or render himself a prisoner, or that they would pay it for him.—In criminal practice recognizances are used both as a means of securing the proper administration of justice by compelling the appearance of a party accused before a magistrate for further examination, or for trial at some superior court, and of securing the attendance of witnesses by binding them, with sufficient sureties, to appear and testify. They are used also as a means of preventing the commission of crimes, by obliging the persons suspected of an intent to commit them to recognize in some penal sum, with pledges or sureties, to keep the peace and be of good behavior for a certain time. A recognizance to keep the peace may be taken by any justice of the peace, from any one who creates an affray or disturbance in his presence, or goes about with unusual attendance or weapons to the terror of the people, or is brought before him by a constable for a breach of the peace; and he is bound to grant it in favor of any person who can show just cause to believe that he is in danger of bodily harm at the hands of another. A recognizance for this purpose is an obligation in the nature of a bond with one or more sureties, entered of record, with condition that if its requirements are fulfilled, and the cognizor keeps the peace for the time therein specified, it shall be void and of no effect. If on the contrary it is broken by any breach of the peace, it becomes forfeited or an absolute debt, and the cognizor and his sureties may be sued for the sums in which they are respectively bound. If it is a special recognizance, as to keep the peace toward any particular person, it may be forfeited by any actual violence, or even an assault or menace, to such person and to such person only. If it is a general recognizance, it is forfeited by any act which tends to break the peace, done to any person or thing in general.—A recognizance may be discharged by the death of the principal party bound thereby (if not before forfeited), or by the order of the court to which it is certified by the justice, if they see sufficient cause, and in England by the death of the king to whom it is made. If granted upon private account, it may be discharged if the person at whose request it was granted will consent to release it, or does not make his appearance to pray that it may be continued.—At the common law a peer or peeress could not be bound to recognize in any other place than the courts of king's bench or chancery; but a justice of the peace had power to require sureties from any person, not a lunatic and under the degree of nobility, whether such person were a fellow justice or other magistrate or merely a private man. Wives may demand it against their husbands, and husbands, if necessary, against their wives; but married women and infants should find security by their friends and not be bound themselves, because they are incapable of engaging themselves to answer any debt. The statutes of Massachusetts make a recognizance to appear as a witness, to the amount of $[illegible] binding upon married women and infants notwithstanding the disability of coverture or minority.—In old practice the verdict of an assize, or strictly the act of the jury in hearing and inquiring into the case in order to the making up of their verdict, was called a recognizance.

RECOLLECTS. See FRANCISCANS.

RECORD (Lat. *recordari*, Fr. *recorder*, to remember), an official contemporaneous memorandum in writing, drawn up by the proper officer of a court of justice, and containing a summary statement of the proceedings in an action at law brought before that court. This statement comprises a short history of the case and the proceedings consequent thereon; as the nature of the action, the names of the parties and the time of their appearance in court, and the acts of the court itself during the progress of the pleadings, arranged in the order of their occurrence, and sometimes connected together by entries of a peculiar nature called continuances, the whole concluding with the judgment of the court with respect to the question at issue. These continuances were adjournments of the case from one day or term to another, which the law allowed for certain purposes, and which were entered with the pleadings and other proceedings on the roll or record, and gave the whole a complete and connected form. These records were always written upon rolls of parchment, which indeed was an essential characteristic of a record. In the United States paper is universally used as a substitute for parchment, and the roll form has consequently been abolished, but otherwise the forms of the English records have been generally adopted. Records in this technical sense are peculiar to the common law; and as they form the only strict and proper proof of the proceedings of the courts in which they are preserved, they are regarded with particular consideration, and are generally a proof of such a high and absolute nature as to admit of no contradiction. In Sir Edward Coke's words, they "import in themselves such uncontrollable credit and verity, as they admit of no averment, plea or proof to the contrary." The existence of a record can only be tried by itself; that is, if in any action the existence of any matter on record is alleged, and the adverse party pleads *nul tiel record*, or that there is no such record, the issue arising thereon is determined merely by the inspection of the record itself by the court, without witnesses or jury, because no issue can be joined upon it to be tried by a jury as upon matters of fact; and the record is conclusive proof without further evidence. The peculiar privilege of some courts to have these memorials has of itself created the great leading distinction, equally recognized in English and American law, between courts of record and courts not of record. Though courts not of record may keep minutes or memorials of their proceedings, such minutes are not properly records. Legally, the term records applies to the rolls of such only as are courts of record, and not to the rolls of inferior or any other courts which proceed not *secundum legem et consuetudinem Angliæ*, or according to the laws and customs of England. During that term of the court in which any judicial act is to be done, or before the case pending is concluded, the record is said to remain in the breast of the judges of the court, and in their remembrance, and therefore it may be altered during that term, in such manner as the judges shall direct. But as soon as that term is ended, the record is closed, and admits of no change, alteration, or proof to the contrary.—The practice of recording is said to be of Norman origin. It existed in the French law, generally, as early as the time of the conquest, if not earlier, and in the same form as that which it bore in Normandy. In the *Assises de Jérusalem*, which was a code of feudal jurisprudence compiled as early as 1099, and intended for the kingdom of Jerusalem then newly established, litigants were directed to collect as many of their own friends as possible in court, and request them to attend to what was said, so that they might retain and record it properly at the time of judgment or trial. They were further directed, if there should be an adjournment or further day appointed for the hearing, that both plaintiff and defendant should put down in writing the nature of the claim and other particulars, in order that they might testify to them at the adjourned meeting if necessary, and thereby assist or confirm the recollection of the judges. This practice finally became developed, from the mere private memoranda of the pleaders, into an official contemporaneous minute of the proceedings. "Whether this change," says Mr. Stephens, "had fully taken place at the date of Glanvil's treatise (in the reign of Henry II.), that work does not enable us accurately to decide. However, we find, at least very shortly after that period, the practice of recording, in the present sense of the term, was in full operation." Next to Domesday Book, which, though not a legislative record, has all the validity of one, is the "Exchequer Register" (Pipe Roll) of 31 Henry I. The series of legal records in the court of king's bench, now extant, reach from the reign of Richard I. to the present day, and were edited by Sir Harris Nicolas (*Rotuli Curiæ Regis*, 2 vols. 8vo.) for the record commission. The peculiar construction of the record, showing as it did every proceeding in the action precisely as it took place, gave it at a very early period the highest authority as a judicial memorial; and its importance in this particular led to a suitable degree of care in framing and preserving it. Its language gradually reached the highest degree of precision and uniformity, and the whole instrument settled at last into a fixed form of expression, which neither admitted of nor required any variation. When written pleadings took the place of oral, they were framed in the same manner as they had previously appeared on the record, and were in fact simply extracts from it, the same concise and technical forms of expression being always used. From this arose a leading principle of practice, viz., that every proceeding in an action intended or required to appear on the record, must be framed in the language of the record, and with the same exactness as the record itself. Two other circumstances united to give the record the unchangeable character which has accompanied it down to modern times, and almost to the present day. One was, that it was kept in Latin, a language which admitted of no variation; and the other was its inviolable character, which preserved it from the slightest alteration after being once made up. The substitution of the English for the Latin language, and of ordinary writing for the "ancient and immutable court hand," took place in the reign of George II., and was considered by competent judges of that time as a dangerous innovation. It has been certainly followed by other important alterations and modifications, which have greatly impaired its original character as a complete and immutable memorial of all the proceedings in an action. The old continuances and the formal commencements and conclusions of the pleadings are now omitted, the language of the pleadings themselves is greatly modified, and the present tendency undoubtedly is to deprive the record in a great measure of the high dignity and importance which it anciently possessed.—Recording, as the title, or rather evidence of title to real estate, by the record or register of title deeds, is of American origin. The usage has prevailed from the early settlement of New England, and is now universal throughout the United States. By the laws of Massachusetts in 1641 all deeds of conveyance, whether absolute or conditional, were required to be recorded, that "neither creditors might be defrauded nor courts troubled with vexatious suits and endless contentions." The statutes of the various states differ in some immaterial respects as to the time and manner of registry, and as to what deeds or instruments must be recorded; but the principle in all is the same, and all make such record absolutely necessary in order to complete the purchaser's title, and render it valid against creditors and subsequent *bona fide* purchasers. If the deed is not recorded, the sale is nevertheless good and the title passes as between the immediate parties and their heirs and devisees, but it is void as against subsequent *bona fide* purchasers and mortgagees whose deeds are first recorded. In some of the states a specified time is allowed in which the deed may be recorded, as one year in Delaware, Georgia, Indiana, and Tennessee, and shorter periods in other states; and in yet others where no time is fixed by statute a reasonable time is allowed, and the deed when recorded within such reasonable time has relation back to the time of its execution, and takes effect according to priority of execution and not according to priority of registry. In 1830 the real property commissioners in England recommended the establishment in that country of a general registry of deeds and instruments relating to land, as contributing to the security of title and the cheapness and facility of transfers of land, and supported their recommendation by referring to the successful operation of the system in the United States and elsewhere. But it has as yet been adopted to a limited extent in England, and its application is restrained to special localities. Freehold but not leasehold property is recorded in Scotland in a public register, and the deed must be recorded within 60 days to render it valid against creditors and purchasers.—It has sometimes been a question whether notice of the transfer of property to a subsequent purchaser was equivalent to a record of the prior deed, and whether the deed of a subsequent purchaser with such notice, duly recorded, would be valid against the prior unrecorded conveyance. The record of a title deed is not considered as conferring title in itself, but merely as evidence of notice or as constructive notice to the public of the title passed by the deed of conveyance of which it is an official and certified copy; and it is therefore a general rule that notice, actual or implied, to a subsequent purchaser of a prior conveyance, is as effectual to defeat his claim as a *bona fide* purchaser as a due record of such conveyance would be; for so long as he receives notice of the prior incumbrance, it makes no difference whether such notice is derived from a record, or from any other authentic source, and he purchases thereafter at his peril. In other words, if he knows that the land he buys has already been conveyed to another person who has neglected to record the deed, he cannot claim the rights of a *bona fide* purchaser.

RECORDE, Robert, an English physician and mathematician, born in Tenby, Pembrokeshire, about 1500, died in 1558. He entered Oxford university in 1525, was elected a fellow of All Souls' college in 1531, and taught rhetoric, mathematics, music, and anatomy. In the latter part of his life he resided in London, and was physician to Edward VI. and to Queen Mary. He wrote the "Gate of Knowledge," and the "Treasury of Knowledge," both of which are lost. His extant works are: "The Urinal of Physic;" "The Castle of Knowledge;" "The Whetstone of Wit," a mathematical work; "The Ground of Arts, teaching the Work and Practice of Arithmetic;" and "The Pathway to Knowledge," a compendium of geometry.

RECORDER, an old-fashioned instrument resembling the flute, with which it has sometimes been confounded, but more akin to the flageolet. Its tone was soft and piercing; whence Milton speaks of "flutes and soft recorders."

RECTOR (Lat. *rego*, to rule), literally, a ruler or governor. The term is used: 1, in the church of England, to designate the clergyman who possesses the tithes of a parish, and who is properly a parson; 2, as the title of the chief elective officer in a college, or of the head of a high school; 3, by the Jesuits for the superiors of their seminaries or colleges.

RECTORY, the office of rector; and, comprehended as a whole, a parish church with its rights, tithes, &c. The name is also given to the residence of a rector.

RECUSANT (Lat. *recuso*, to refuse), a term of frequent occurrence in English ecclesiastical history, and used to designate those persons in general, who refused or neglected to attend divine service on Sundays or holidays in the established church, or to worship God according to its forms. The use of the word in temporal courts is traced to the first year of Queen Elizabeth, when it was enacted that all persons who, without reasonable excuse, failed to attend some usual place of prayer, should be censured and fined for every omission 12 pence. In 23 Elizabeth the fine or forfeiture was raised for every month 20 pounds; and in 35 Elizabeth it was enacted that if recusants failed to submit within 3 months after conviction, they might, upon the requisition of 4 justices of the peace, be compelled to abjure and renounce the realm; and if they did not depart, or if they returned without license of the crown, they were guilty of felony and should suffer death without benefit of clergy. In the case of recusants who professed the Roman Catholic religion, and who were designated popish recusants, the laws were more severe; in addition to the above general penalties, they were disabled from taking lands, either by descent or purchase, after the age of 18, until they renounced their errors, and were incapacitated for several minor rights of the subject. "Popish recusants convict," as they were called, after having been once convicted, were virtually outlaws. Protestant dissenters were relieved from the penalties of recusancy at the revolution by the toleration act; and in 1829, by the Catholic relief act, Popish recusants were exempted from prosecution; but the statutes against recusancy still exist, though they are but seldom enforced, against persons who absent themselves from church, being neither Roman Catholics nor Protestant dissenters.

RED, the most brilliant of the colors of the solar spectrum, seen in nature in the arterial blood, which is of a medium hue between crimsons that partake of blue, and orange—the color of flame, that borders on yellow. Beside these shades of red a number of others are recognized, as scarlet, vermilion, and Indian red; the first of a brilliant hue lighter than crimson, the second a very bright red, and the ed of a dark shade. The color often results from slight modifications of the manner in which the light is reflected from the surface of bodies, as in the colors of fruits, flowers, insects, &c., the hue changing with the movement of these bodies. So, too, apparently insignificant modifications in the chemical composition of bodies, as a slight accession or diminution of oxygen, determines a red, blue, brown, yellow, or black color. In nature brilliant reds are seen in the plumage of birds of tropical climes, and in insects and fishes. Infusions of the cochineal insect furnish the rich carmine; and from those of the safflower are prepared the beautiful vegetable rouge. (See Carthamus, and Rouge.) Many ripe fruits and berries display rich red colors; and in the mineral kingdom they are seen in the highest perfection in the ruby and in the peroxides of iron or ochres, which with red lead or minium (see Lead, vol. x. p. 289) furnish the materials for the common red paints. The red oxides of copper and of silver, cinnabar (sulphuret of mercury), the chromate of lead, and a variety of other metallic ores and minerals, display beautiful red colors. In the depths of the sea the corals and shells of the mollusca assume brilliant shades of red; and some of the crustaceans, as the lobster, become red on being boiled in water. The peculiar qualities of the color are referred to in the article Color; and some special preparations of it in the articles Carmine, Cochineal, Rouge, &c.

RED BIRD. See Grosbeak.

RED JACKET, a North American Indian, chief of the Senecas, an Iroquois tribe, born about 1759, died near Buffalo, N. Y., Jan. 20, 1830. His Indian name was Sagoyewatha or Saguwatha (the keeper awake). His English name was due to a richly embroidered scarlet jacket given him by the British during the revolution, which he constantly wore. He won distinction in his tribe as an orator, and boasted that he "was born an orator." There is reason to believe that he was among those Senecas who during the revolution distinguished themselves by their ravages on the frontiers of New York, Pennsylvania, and New Jersey. At a council held at Fort Stanwix, in 1784, to negotiate a treaty between the United States and some of the Six Nations, for the cession of lands, he spoke very eloquently against the treaty. It was nevertheless ratified; but Cornplanter, who was then chief of the Senecas, and advocated it, lost his popularity in consequence, and was ultimately supplanted by Red Jacket. A few years later, Red Jacket had an interview with Gen. Washington, who gave him a silver medal which he wore ever afterward. In 1810 he gave information to the Indian agent of the attempt made by Tecumseh to draw the Senecas into the western combination; and in the war with England of 1812 he offered the service of his tribe to the United States. They took part in several skirmishes, and the courage of Red Jacket was particularly conspicuous in an action near Lake George on Aug. 19, 1812. He always strenuously resisted the advances of civilization, but gradually became in his later years a confirmed drunkard.

RED LEAD. See Lead, vol. x. p. 289.

RED RIVER, a tributary of the Mississippi, and the last of considerable size which it receives. It is formed by the confluence of two principal branches, of which the southern and larger rises in New Mexico, a little beyond the W. boundary of Texas, lat. 34° 42' N., long. 100° 7' 10" W.; the northern in Texas, lat. 35° 35' 3" N., long. 101° 55' W. After the junction, near lat. 34° 30' N., long. 100° W., it flows nearly E., separating the Indian territory from Texas; a little beyond the extremity of the latter, at Fulton, Ark., it bends to the S. and enters Louisiana; thence flowing S. E., it enters the Mississippi 341 m. from its mouth. Capt. Marcy, by whom the river was explored, estimates its entire length, including the south fork, at 2,100 m., of which the main stream is 1,200 m. He states that the main or southern branch has its sources in the fissures of an elevated and barren plain, the Llano Estacado, at an altitude of 2,450 feet above the sea. For about 60 m. the banks rise perpendicularly from 500 to 800 feet. After leaving the Llano Estacado it flows for 500 m. over a broad bed of light shifting sands through an arid prairie country. It then enters a most fertile country, covered by gigantic trees. "Here the borders contract, and the water for a great portion of the year washes both banks, carrying the loose alluvium from one side and depositing it on the other, in such a manner as to produce constant changes in the channel, and to render navigation difficult. This character continues throughout the remainder of its course to the delta of the Mississippi; and in this section it is subject to heavy inundations, which often flood the bottoms to such a degree as to destroy the crops, and occasionally, on subsiding, leaving a deposit of white sand, rendering the soil barren and worthless." The principal tributaries are the Big and Little Washita, from the N. It is navigable for 8 months of the year to Shreveport in the N. W. of Louisiana, and continually to Alexandria, about half the distance. The Great Raft, a very serious obstruction to the navigation of the river, consists of an immense collection of trees and drift wood, which commences about 30 m. above Shreveport and extends 60 or 70 m. up the river, spreading out to a width of from 20 to 30 m., and dividing the main body of the river into a great many channels, which are not all united until near Natchitoches, a distance of nearly 100 m. After a short distance a large portion of the waters is again diverted, supplying a great number of lakes, channels, and bayous along its banks. The raft was partially removed by the U. S. government in 1834-'5, at an expense of $300,000, but another has since been formed, interrupting navigation about as much as its predecessor.

RED RIVER, a N. E. co. of Texas, separated from the Indian territory by Red river, and bounded S. by Sulphur river, one of its branches; area, about 1,200 sq. m.; pop. in 1860, 8,534, of whom 3,039 were slaves. It has an undulating surface and fertile soil. The productions in 1850 were 95,510 bushels of Indian corn, 16,090 of oats, 7,338 of sweet potatoes, and 579 bales of cotton. There were 2 churches, and 257 pupils attending public schools. Capital, Clarksville.

RED RIVER of the North, a river which has its source in a collection of small lakes lying in central Minnesota, the largest being Otter Tail lake. The main stream flows for about 50 m. S. W., then makes a turn to the N. W., receives the Bois des Sioux, and inclining more nearly N., passes through Minnesota into the Hudson's Bay territory, falling into Lake Winnipeg after a course of about 500 m. A great number of streams from the lakes abounding near its source contribute to its waters, and throughout its whole length its tributaries succeed each other at short intervals. The largest of these are the Shayuen, Buffalo, Manomin or Wild Rice, Red Lake river, and Pembina.

RED SEA, anciently known as the Arabian gulf, a large sea lying between Africa and Asia, separating Egypt, Nubia, and Abyssinia in the former from Arabia in the latter. It extends in a straight course nearly N. N. W. and S. S. E. from lat. 12° 30′ to 30° 2′ N., having a total length according to Dr. Buist of 1,230 m., measured from the straits of Bab-el-Mandeb at the S. to Suez at its N. termination. Its greatest breadth of 192 m. is in lat. 17°, and toward each extremity the sea narrows; at lat. 14° it is 72 m. wide, and about the same in lat. 27° 20′ From this point N. the sea is divided into two narrow branches. The principal one is the western, called the gulf of Suez, and is the proper continuation of the Red sea; it is 167 m. long, and its width is usually about 20 m. The other, called the gulf of Akabah, extends about 100 m. N. by E. with a maximum width of 16 m.; at the mouth the width is 7 m. This branch occupies a deep depression between mountainous regions on each side, and beyond its N. extremity this is continued in the long narrow valley, Wady-el-Arabah, which runs toward the Dead sea. The depth of water in the gulf of Akabah for ⅔ of its length is about 700 feet, and at one spot no bottom was found at 1,200 feet. The gulf of Suez is about 125 ce t deep, and the greatest depth found is 300 dep In the Red sea a depression of 5 to 10 at 2, width is reported to occur down the 6,000 fe portion of from 1,000 to 1,500 feet in across th lat. 25° 20′ no bottom was found depth near t, and also at another spot at tween this and ear the outlet a shoal extends over 700 feet. from Mocha, the maximum hannel being 240 feet. Between straits the water deepens to nall island, called Perim, recently taken possession of by the English, lies in the mouth of the Red sea, dividing the passage into the great straits on the W. side and the little straits on the E., the former about 13 m. wide, and the latter 1¾ m.; vessels usually pass by the narrower channel. The total area of the Red sea is estimated at 108,15[illegible] sq. m., of which the gulf of Suez includes [illegible] sq. m., and the gulf of Akabah 800. No large islands are met with, but many groups of small islands and of coral reefs and islands lie near the shores, especially in the S. portion of the Red sea. To the S. of lat. 16° the islands are volcanic, and on Gibel-Teer in lat. 15° 30′ is an active volcano rising 900 feet above the sea. On both coasts of the S. portion ranges of volcanic hills extend parallel with the shore, in Africa about 14 m. distant from it. N. of lat. 16° on the African side isolated hills form a considerable part of the coast, and the mountain ranges are further in the interior. All around the Red sea mountains are everywhere in sight, and the region lying between the two gulfs at the N., known as the peninsula of Mt. Sinai, is a district of mountains and deserts. Mt. Sinai itself is midway between the gulfs, about 50 m. N. of the extremity of the peninsula. As no rivers run into the Red sea and the region has but little rain, while the evaporation from the surface of the sea is estimated to amount to a depth of 8 feet annually, it has been supposed that the water must be exceedingly salt. It is found, however, to contain only 39.2 to 41 grains of saline matter in 1,000, which is even less than that of sea water in some places; and it is therefore probable that the waters most charged with salt form an under current which flows out through the straits as the lighter and less saline upper current flows in. The waters of the sea are remarkable for their high temperature, particularly in the volcanic region between lat. 1[illegible] and 21°. Even in the winter months they seldom fall below 80°. In March and April their temperature is sometimes 84°, and in May 90°. In Nov. 1856, at a time when the air was at 82°, the water was observed to be at 10[illegible]. This explains the occurrence of coral reefs in the Red sea in more northern latitudes than they are elsewhere found. They are very numerous about a quarter of a mile off the shore, and seriously obstruct the navigation. A channel for small vessels is commonly found within the reefs, but the shores are in great part inaccessible to large vessels. Some of the huge specimens of *meandrina* and *favia* observed by Ehrenberg, of 6 to 9 feet diameter, from the rate of growth of these species are regarded as several thousand years old, and must have been growing in the time of the Pharaohs. The winds are either up or down the sea. From October to May or June they blow from the S. S. E., being strongest in February; the rest of the year they are from the N. N. W. and strongest in June and July. Light showers occasionally fall from November to March.

he tides at the head of the sea rise to the ight of 5 feet, and the spring tides to 7 feet. he winds, however, greatly affect the height f the water, as is felt especially in the shoaler arts near Suez, where the gulf is sometimes orded by the Arabs at low tide, and after the revalence of northerly winds. It was forerly supposed from the measurements of M. epère that the surface of the Red sea at high ide was about 30 feet higher than that of the editerranean near Alexandria; but the survey f Mr. Robert Stephenson, a report of which as made to parliament in 1851, shows no difrence in the elevation of the two seas. The istrict between the head of the gulf of Suez nd the gulf of Pelusium, the nearest point f the Mediterranean, is low, much of it not ore than 6 feet above the level of the seas, nd a portion of this tract is composed of kes ranging along from one sea toward the ther, all together indicating that a communiation formerly existed between the two seas. o open this communication by a ship canal has ong been regarded as most desirable, and was a avorite project of Napoleon I. In 1859 the enerprise was undertaken by a French engineer, M. F. de Lesseps, who had acquired in 1854 rom the viceroy of Egypt the exclusive right, nd up to Nov. 1858 had obtained subscriptions or carrying out the enterprise amounting to 8,000,000. The canal is to be 90 miles long, 20 feet wide at the water line, and its bottom 29 feet below low water level in the Mediteranean. The difficulties to be encountered in his work, and in constructing the harbors at ach end, are so great that the successful issue of the undertaking is still considered doubtful. The importance of such a connection ither with the Mediterranean or the Nile was appreciated even in the time of the ancient Egyptian kings; and, as stated by Humboldt: "The execution of a canal was begun, f not by Sesostris, to whom Aristotle and Strabo ascribe the undertaking, at any rate by Neku, although the work was relinquished in consequence of the threatening oracular denunciations directed against it by the priests. Herodotus saw and described a canal completed by Darius Hystaspis, one of the Achæmenidæ, which entered the Nile somewhat above Bubastes." This canal was kept in operation at the time of the Roman dominion under Marcus Aurelius, or even as late as Septimius Severus. It was by the Red sea in ancient times, before the discovery of the passage around the cape of Good Hope, that the trade between the countries on the Mediterranean and India was carried on; and upon this sea and the other inland gulfs and seas of this part of the old world the earliest commercial operations were conducted and the first experience in navigation was gained. The Egyptians and Phœnicians established this trade with India, and so important was it to the former people, that, as recorded by Herodotus and Diodorus, Sesostris had upon the Arabian gulf a fleet of 400 long vessels or ships of war, by means of which he efficiently protected it and subjugated the people on the borders of the sea that interfered with it. Two important ports, Berenice and Myos-Hormos, were established on the African side, from which communication was opened with the Nile; from the former by an admirably constructed road of 258 miles. Over this the transportation was by camels, and from Coptos by boats to Alexandria on the Mediterranean. The Phœnicians also seized from the Idumeans some important places near the N. E. extremity of the Arabian gulf, and from these sent their ships in the one direction to India and the S. coast of Africa, and in the other to the N. W. head of the gulf, whence their cargoes were transported over land to the harbor of Rhinocolura on the Mediterranean, of which they had also obtained possession, and thence by sea to their own ports. In the middle ages the Genoese and Venetians were largely engaged in this trade, until the Portuguese destroyed it by their adoption of the more economical route to India round the cape of Good Hope. The Red sea thus lost entirely its commercial importance; but this has been in part revived by the establishment by the English of what is known as the overland route to India, which is the old route by the Mediterranean and the Red sea, the only land passed over being from Cairo to Suez, a distance of 84 m., traversed by a railroad recently completed. The principal ports on the Arabian side are Jiddah, Hodeida, and Mocha. The export trade in coffee has now almost forsaken Mocha for the neighboring port of Hodeida. Massowah is the principal town on the African side, and its exports of coffee, myrrh, incense, hides, gum, ivory, senna, slaves, and gold dust are estimated to amount to the value of about $2,000,000 annually.—The Red sea is often referred to in the Old Testament, under its Hebrew name of *Yam Suf*, the sea of weeds. It was thus called, it is supposed, from the abundant plant-like growth of corals seen upon the bottom. The name Red applied to it is variously explained. It is a translation of the Latin *Rubrum* and Gr. Ἐρυθρά, which were applied to this sea in common with the Persian gulf and Indian ocean by Herodotus and other ancient writers. The original name, some suppose, was derived from that of an ancient monarch of Arabia, Erythras, and was not intended to refer to the color, which this name means; this is the explanation of Pliny, Strabo, Curtius, &c. Others suppose it is from Edom, the ancient name of the neighboring country, which in Hebrew and Phœnician means red. It is also believed that the abundance of red coral found in the sea suggested the name; and Dr. Buist and others assert that it comes from the multitudes of animalcules that in the spring cover the surface of large portions of the sea in patches sometimes several miles square, and give to the water an intensely blood-red color. The most interesting historical incident connected with the Red sea is the passage of the Israelites across its bed in their escape from Egypt, as recorded in the Old Testament; and much controversy has grown out of the question as to the point where this passage was made, some contending that it was 18 m. S. of Suez, where the sea is 12 m. wide, and others that it was in the immediate vicinity of this town, where the sea is now fordable at low tide, and its breadth is only about 3,500 feet. Here, the waters being kept down by the strong E. or N. E. wind, as described by Moses, the passage of the immense hosts may have been completed on the ebb tide, and the returning flood, which still comes in with considerable rapidity, must have overwhelmed the armies that pursued them. This appears to be the only place where the strong east winds, which from the scriptural account the Lord made the active cause of the miraculous removal of the waters, could have produced this effect, and where the passage of a great multitude could have been made in a single night.

REDBREAST. See Robin.

REDDING, Cyrus W., an English journalist and author, born in Penryn, Cornwall, in 1785. In 1805 he went to London, was engaged upon the staff of an evening newspaper called "The Pilot," and subsequently established and conducted for several years the "Plymouth Chronicle." From 1815 to 1818 he resided in France, where he edited "Galignani's Messenger." In 1820 he became editor, in conjunction with the poet Campbell, of the "New Monthly Magazine," and during 10 years remained in that position, having in his hands almost the entire executive control of the magazine. In 1830, in consequence of a quarrel between Campbell and the publisher Colburn, the former left the "New Monthly," taking with him Redding, and began the publication of the "Metropolitan," which proved unsuccessful. Subsequently he edited for two years a liberal political newspaper, called the "Bath Guardian," and in 1836 established the "Staffordshire Examiner," a journal advocating similar political views. After editing this sheet for 5 years he returned to London in 1840, and is now connected with the "Examiner." He has written much, but is most widely known by his "History of Wines" (1833).

REDEMPTION, Equity of. See Equity of Redemption.

REDEMPTORISTS, or Congregation of the Most Holy Redeemer, the name of the youngest among the great monastic orders of the Roman Catholic church. It was founded in the year 1732 by Alfonso de Liguori at Scala, in the province of Benevento, on nearly the same basis on which, about a century before, St. Vincent de Paul had established the congregation of the priests of the mission. At first the new congregation had to overcome the opposition of several priests of high position, as the archbishop of Naples; but in 1749 it was confirmed by Pope Benedict XIV., who bestowed upon its members many favors and privileges, and induced them, for fuller distinction from the canons of the Most Holy Redeemer, to adopt the name Redemptorists. After their founder they frequently were and still are called Liguorians. The rule of the Redemptorists prescribes, beside the three usual monastic vows, a fourth, which obliges the members to accept outside of the order no dignity, office, or benefice, except upon an express order of the pope or the superior general, and not to leave the order unless by special permission of the pope. The principal sphere of action of this order has been the conducting of what is called a "mission," lasting one, two, or sometimes even more weeks, during which time the missionaries endeavor to prevail upon all the members of a church to devote their time principally to religious exercises and a thorough reformation of their lives. These missions frequently attract immense crowds from the neighboring congregations. On account of their great similarity of object and action with the Jesuits, they have been sometimes confounded with the latter; the names of both orders have been often linked together, and in more than one European country the names of both stand side by side in the same decree of proscription. The order spread early from Naples into Sicily and the Papal States; but even before the death of the founder all the houses in the kingdom of Naples were excluded from the order, because they had procured the ratification by the government at the expense of important and unauthorized alterations of their rule. The division lasted until 1790, when a reunion was effected. The first German members established missions in Courland and at Warsaw, but both succumbed to the wars arising out of the French revolution. In Austria they have had since 1808 many influential patrons, and it has ever since remained one of the most important provinces of the order. In France they suffered some losses from the interference of the government in 1830, and again in 1861. They have found an important sphere of action in the United States of America, where they principally labor among the German population. A number of American members, among whom Fathers Hecker and Hewitt are best known, left the order by special permission of the pope, in order to found an independent organization for missionary purposes, better suited to this country, called the Paulists, who established their first house in the city of New York in 1858. In 1860 the Redemptorists had 30 houses in Italy, 21 in Germany, 9 in France, 9 in Belgium and Holland, 4 in the British islands, and 10 in the United States (at Annapolis, Baltimore, Buffalo, Cumberland, Detroit, New Orleans, New York, Philadelphia, Pittsburg, and Rochester). Altogether they had in these establishments about 1,300 members.—A congregation of Redemptorist nuns, which was likewise founded by Liguori in 1732, has never extended itself widely; it counted in 1860 only 1 house in

Italy, 4 in Germany, 2 in Belgium and Holland, and 1 in Third street, New York.

REDEN, Friedrich Wilhelm Otto Ludwig, baron, a German statistician, born in the principality of Lippe-Detmold, Feb. 11, 1804, died in Frankfort-on-the-Main in Nov. 1857. He was graduated as doctor in law at the university of Göttingen in 1814, and entered the public service in Hanover. In 1832 he was elected a deputy in the first chamber, assisted in framing the constitution of 1833, and in 1834 became secretary-general of the minister of finances. Upon the accession of King Ernest Augustus in 1837, and his arbitrary restoration of the constitution of 1819, Reden retired from office, travelled in various parts of Europe, and made a large collection of statistical documents. In 1841 he was made special director of the railroad from Berlin to Stettin, established himself at Berlin, and shortly after received the chair of economical and administrative sciences in the university of that city. He represented a Hanoverian district in the national assembly at Frankfort, and sat in the assembly of the states of Hanover in 1849. By his course in the latter body he incurred the displeasure of the Prussian government, and was deprived of his several positions under it. He left many works on statistical subjects.

REDFIELD, William C., an American meteorologist and geologist, born in Middletown, Conn., March 26, 1789, died in New York, Feb. 12, 1857. At the age of 14 he was apprenticed to a saddler at Upper Middletown, now Cromwell, but studied diligently by the firelight in the winter evenings. At the close of his apprenticeship, Mr. Redfield set out on foot to visit his mother in Ohio, following nearly the present course of the New York central railroad, and keeping a daily journal of his observations. Spending the winter in Ohio, he returned in the spring by a more southern route, nearly that of the Baltimore and Ohio railroad, and labored at his trade in Upper Middletown for nearly 14 years, keeping also a small country store. In Sept. 1821, a violent hurricane, long known as the "great September gale," passed over the Atlantic states. It was then universally believed that in hurricanes or wind storms the wind blew in right or straight lines. In a journey which Mr. Redfield made soon after the gale into Massachusetts, he found that the wind, which at Middletown had blown from the S. E., had, at a point less than 70 m. distant, blown from the N. W. at the same moment; and further observation convinced him that the storm, instead of taking a straight line, had rotated around a central point, and that its movement had been in curved lines. In 1821 or 1822 he had become interested in steamboat navigation, and when the public had been terrified by repeated explosions of steamboat boilers, he devised and established a line of safety barges for passengers to be towed by steamers, at such a distance as not to endanger the passengers in case of explosion. When this terror had died away, he applied the same principle to freight boats, and originated a transportation line of tow boats and barges on the Hudson, to which he gave the appropriate name of the Swiftsure line, and for the remainder of his life was actively engaged in its management, making New York his residence. He investigated thoroughly the whole subject of the connection of steam with navigation, and in pamphlets, essays, and published letters, some of them called out by government inquiries, he discussed the causes of steamboat explosions, the means of safety, the necessity of careful and frequent inspection, the improvement of the law relative to steam navigation, its adaptation to the purposes of national defence, and the simplification and improvement of marine engines. In 1829 he published a pamphlet urging the importance of a system of railways to connect the waters of the Hudson with those of the Mississippi. At the time this pamphlet was published, the Erie canal was but just completed, only a few miles of railway had been constructed in the United States, and locomotives were not yet introduced. The same year he conceived the idea of street railroads in cities, and petitioned the common council for permission to lay the track for one in Canal street, New York. He subsequently explored the route and aided in obtaining the charter of the Harlem railroad, and still later promoted the building of the Hartford and New Haven and the Hudson river railroads. In 1831 he first gave to the public, through the "American Journal of Science," his "Theory of Storms," and 2 years later his elaborate article on the hurricanes of the West Indies appeared in the same journal. These were followed by many other essays, narratives, and tables of particular hurricanes; and the corps of observers who had become interested in the subject through his earlier essays comprised many eminent scientific men, with several of whom he maintained a correspondence for years. (See Hurricane, Meteorology, and Reid, Sir William.) Subsequently to the year 1836 he devoted much time to the investigation of the fossil fish of the Connecticut valley and the sandstones of the Atlantic coast in New Jersey, Virginia, and North Carolina, and had made a very large collection of them. He prepared several papers on these fossils, which were read before the American association for the advancement of science; and in the last of these, read in 1856, and subsequently published in the "American Journal of Science," he demonstrated that the fossils of the Connecticut river valley and New Jersey sandstones, to which he gave the name of the *Newark group*, belonged to the Jurassic period. He published during his life 62 distinct essays, of which 40 pertain to meteorology.

REDHEAD. See Duck, vol. vi. p. 646.

REDING, Aloys von, a Swiss patriot, born in the canton of Schwytz in 1755, died in Feb. 1818. He first entered the Spanish service, but in 1788 returned to Switzerland. On the French invasion of 1798, he summoned the forest and mountain cantons to the succor of Bern, and at the head of the army of the canton of Schwytz, 3,000 strong, held the French army in check for 2 days at Morgarten. Overcome at last by superior numbers, they accepted the convention; and after the formation of the Helvetian republic Reding was one of those who zealously advocated the restoration of the old federal constitution. After the departure of the French almost all the cantons declared themselves against the government, and Reding called at Schwytz a general meeting, which assembled Sept. 27, 1802, and devoted itself to the formation of an independent political system. As head of the provisional government he had in 1801 gone to Paris to impress upon Bonaparte his plan of administration, but had been unsuccessful in his mission, was made prisoner by Marshal Ney, when by Bonaparte's orders that officer interfered in Swiss affairs, and imprisoned at Arbourg. In 1803 he was made *landamman* of Schwytz, then retired to private life, and in 1809 was again called to occupy his old position. In 1813 he conducted the negotiations with the Rhenish confederation, in regard to the neutrality of Switzerland.

REDOUTÉ, PIERRE JOSEPH, a French painter of flowers, born at St. Hubert, near Liége, Belgium, July 10, 1759, died in Paris, June 19, 1840. He belonged to a family of painters, and, having settled in Paris, painted some of the most elegant flowers in the series known as the *Collection des velins*, commenced under Louis XIV. and still continued under the supervision of the academy of fine arts; and in 1822 he succeeded Van Spaendonck as professor of vegetable iconography at the *jardin des plantes*. His magnificent works, *Les liliacées* (8 vols. fol., Paris, 1802–'16), and *Les roses* (3 vols. fol., 1817), are the finest known specimens of botanical illustration. A copy of the former on vellum, with the original drawings, was purchased by the empress Josephine for 84,000 francs.

REDPOLL. See LINNET.

REDSHID PASHA. See RESHID PASHA.

REDSTART, the common name of the warblers of the American genus *setophaga* (Swains.). The bill is as in other flycatchers, and abruptly curved and notched at the tip; the wings rounded, with the 2d to 4th quills longest; tail long, graduated, and broad; tarsi and toes short. There are many species, mostly in South and Central America, brilliantly marked with red, yellow, and black; the South American species have more or less yellow in their plumage, and the Mexican are usually black and red. The best known species in North America is the common redstart (*S. ruticilla*, Swains.); it is about 5¼ inches long with an alar extent of 8; in the male the prevailing color is black, with the base of the wings and tail and sides of breast reddish orange; abdomen, under tail coverts, and central line on breast white; in the female the black is replaced by olive green above and brownish white below, the head is ashy, and the red is changed to yellow. It is found throughout the eastern United States to the plains of the Missouri, and sometimes wanders to the West Indies in winter; it is a very handsome bird, always in motion on the trunks and branches of trees in search of insects and larvæ, jumping quickly from side to side, displaying the brilliant tail at every movement, and now and then darting off after an insect on the wing, or descending to the ground in a spiral or zigzag manner; it also pursues other birds as if in sport, snapping the bill violently. The nest is placed in a low bush, suspended to the twigs, and is of delicate structure; the eggs are 4 to 6, white, with ash-gray and black spots; a single brood is raised in a season.—The European redstart belongs to a different sub-family of the warblers, and to the genus *ruticilla* (Brehm), peculiar to the old world. The *R. phœnicura* (Brehm) is a little more than 5 inches long; in the male the bill, legs, feet, cheeks, and throat are black; the breast, rump, and sides red; forehead white; crown, hind neck, and back deep blue-gray. It occurs all over Europe, and is a visitor to Great Britain from April to September; unlike its American ally, it is a very fine songster, heard the summer long in orchards, hedge rows, gardens, and ivy-covered walls; the male is very affectionate, and sometimes sings to his mate as late as 10 at night and as early as 3 in the morning; it feeds on insects, worms, and berries; the eggs, 4 to 6, are greenish blue, and laid in holes of trees or in a nest on the ground. It is much prized as a cage bird for its beauty and its song; if taken young, it may be taught to imitate the notes of most other birds, and even to whistle a tune. The name in both hemispheres is derived from the constant jerking motions of the bird, displaying the red of the tail.

REDWING. See BLACKBIRD.

REDWITZ, OSCAR, baron, a German poet, born in Lichtenau, near Anspach, June 28, 1823. He spent nearly 5 years in the university of Munich in the study of philosophy and law. In the autumn of 1851 he was called to Vienna as professor of general literary history, but resigned his position in 1852 in order to devote himself to literary pursuits. His works have passed through numerous editions.

APPENDIX.

QUAKERS.* The society of Friends, commonly called Quakers, is a body of Christian professors which arose in England about the middle of the 17th century. Many of those who joined it belonged to families of high respectability, and had been distinguished for their piety. The ministry and labors of George Fox were chiefly instrumental under the divine blessing in convincing them of the Christian principles held by Friends, and his labors contributed largely to their establishment as a regularly organized body. He was born at Drayton, Leicestershire, in 1624, and educated in the Episcopal worship. From childhood he led a religious life, and being apprenticed to a shoemaker who also kept sheep, his occupation was chiefly that of a shepherd. Passing much of his time in retirement and being earnestly engaged for the salvation of his soul, he diligently read the Holy Scriptures, waiting on the Lord to be taught by his Spirit their true meaning. In this state of humble dependence, he was enlightened to see the spiritual nature of the gospel dispensation, and was favored to experience the work of redemption. Receiving a divine call to the ministry, he commenced his labors in the year 1647, and, from a conviction that it was contrary to Christ's command, refused to receive compensation for preaching. The purity of his life and the heavenly unction attending his ministry carried conviction to the hearts of the people, and multitudes embraced the principles he promulgated. Speaking of his mission, he says: "I was sent to turn people from darkness to light, that they might receive Christ Jesus; for to as many as should receive him in his light, I saw that he would give power to become the sons of God, which I had obtained by receiving Christ. I was to direct people to the spirit that gave forth the Scriptures, by which they might be led into all truth, and so up to Christ and God, as those had been who gave them forth. I saw that Christ died for all men, was a propitiation for all, and enlightened all men with his divine and saving light, and that none could be true believers but those that believed therein." In a few years meetings were settled in nearly all parts of the kingdom, and notwithstanding the persecution to which the society was subjected because of its testimony against oaths, a paid and man-made ministry, war, using false and flattering compliments, and the plural pronouns to a single person, &c., its members increased, and manifested a zeal, devotedness, and love of each other, which excited admiration even in their opposers. Numerous ministers, divinely called to and anointed for the work, travelled through Great Britain, and on the continent of Europe, where many meetings were settled, and some went to Asia and Africa. Many came to America, enduring great hardships in their journeys through the wilderness; and a large body of Friends, under the patronage of William Penn, emigrated from the mother country and settled in Pennsylvania.—When it is considered that all who regularly attended the meetings of Friends, as well as their children, were viewed as members, it is obvious that some system of church government was necessary by which their conduct might be regulated and controlled. George Fox early began the establishment of meetings for discipline, and in a few years had the satisfaction of seeing its accomplishment both in Europe and America. The first objects of attention in these meetings were the care of the poor, the maintenance and education of orphans and poor children, the orderly accomplishment of marriages, the registry of births and deaths, the granting of certificates of approval to ministers travelling abroad, and preserving an account of the sufferings of Friends in support of their religion. While it was to be expected that offences would arise, it did not necessarily follow that the erring one must be cut off; and measures were adopted for extending brotherly labor, in the spirit of love and meekness, for the restoration of such. When brought sincerely to condemn his error and amend his way, a brother is gained; and if this desirable result is not attained, the church testifies against his misconduct and declares that he is no longer a member of it. This is the extent of the censure pronounced by the society, and its proceedings are founded on the directions given by our Lord in Matt. xviii. 15–20. The disciplinary care of the society was also exercised to preserve its members from denying or impugning its Christian principles. The records of the monthly meeting held at Haverhill, England, the 9th of first month, 1676, contained a minute disowning Jeffery Bullock for contravening the doctrines of Friends by "affirming that he expects neither justification nor condemnation by that Christ that died at Jerusalem." At London yearly meeting held 1694, a rule was adopted for dealing with persons, if any such there were, professing with Friends, who "held any such gross errors or false doctrines as are against the validity of Christ's sufferings, blood, resurrection, ascension, or glory in the heavens, or any way tending to the denial of the heavenly Man, Christ." The discipline adopted at an early period by the American yearly meetings contains a rule for dealing with and disowning members who persist in "denying the divinity of our Lord and Saviour Jesus Christ, the immediate revelation of the Holy Spirit, or the authenticity of the Holy Scriptures;" and at different periods persons have been disowned for such errors. There are four grades of meetings for discipline: first, preparative, which prepare business for the second or monthly meetings, in which the executive power is chiefly lodged; then the quarterly meetings, consisting of several monthly meetings, and exercising a supervisory care over them; and lastly the yearly meetings, which include the whole society within a prescribed district, possess exclusively the legislative power, and annually investigate the condition of their subordinate meetings. In each preparative meeting there are usually two or more Friends of each sex chosen as overseers to take cognizance of any improper conduct of the members, to admonish them in love, and if necessary report the case to the preparative meeting. From this it generally goes to the monthly meeting, where a committee is appointed to endeavor to convince and reclaim the offender. The women have similar meetings and the like order and care for the help and preservation of their members, but take no part in the legislative proceedings of the society. There are also distinct meetings for the oversight and help of the ministry, composed of ministers and elders, the latter being prudent religious Friends chosen especially to have the care of the ministry. To monthly meetings belong the requisite care for the reception of persons into the society, the application for that purpose being first made to the overseers; also the granting of certificates of membership to Friends moving from their limits, the allowance and oversight of marriages, the free education of the children of the poor, and the maintenance of such members as are unable to support themselves.—When a member believes himself or herself divinely called to speak in the religious meetings of Friends as a minister, after a sufficient time has been allowed to make proof of the call, if the preparative meeting of ministers and elders unite in the judgment that a gift of gospel ministry has been committed to the individual, it so reports to the monthly meeting; and if this comes to a like decision, it forwards the case to the quarterly meeting of ministers and elders; and when it also unites in the conclusion of the others, the person is recorded as an approved minister.—The doctrines of the society may be briefly stated as follows, viz.: They believe in one God, the creator and upholder of all things; and in his Son, the Lord Jesus Christ, by whom are all things; and in the Holy Spirit which proceedeth from the Father and the Son: one God, blessed for ever. In treating of the Three that bear record in heaven, they prefer keeping to the language of Holy Scripture, which sometimes induced their opponents to accuse them of unsoundness. This was the case in the controversy which led to the writing of William Penn's "Sandy Foundation Shaken." He says the question between him and his opposer was, "whether we owned one Godhead subsisting in three distinct and separate persons." The latter words Penn argued against as unscriptural, but, to prevent a misconstruction of his views, says: "Mistake me not, we never have denied a Father, Word, and Spirit, which are one; but men's inventions;" and at different periods of his life he strenuously repelled the charge of Socinianism as regarded himself and the society. The same applies to his argument respecting the doctrine of Christ's satisfaction; for while he rejects the school terms in which his antagonist dressed it, he quotes numerous passages of Scripture proving that our Lord Jesus Christ, in his suffering and death, was a most acceptable sacrifice and propitiation for the sins of mankind. They own and believe in Jesus Christ, who was conceived of the Holy Ghost and born of the Virgin Mary, in whom we have redemption and pardon through his blood, even the remission of our sins; that he was a most satisfactory sacrifice for the sins of the world, being crucified without the gates of Jerusalem, rose from the dead the third day, ascended into heaven, and now sitteth at the right hand of God, our holy mediator, intercessor, and advocate with the Father. They have uniformly believed that he is true God and perfect man in wonderful union, and that the forgiveness of sins which any partake of is only by virtue of his sacrifice. That the Holy Spirit whom Christ said he would send, leads and guides his followers into all truth; that a manifestation of this Spirit is given to every man to profit withal, which convicts of sin, and, as it is obeyed, gives power to overcome and forsake it; that it enables savingly to understand the Holy Scriptures, and gives the livg experience of those things which belong the soul's salvation. Man was created in e image of God, capable of understanding nd obeying the divine law, and of holding ommunion with his Maker. Through trans- ression he fell and lost this heavenly state. is posterity come into the world in the image f the fallen earthly man, and until renewed y the regenerating power of Christ Jesus, they re dead to the spiritual life in which Adam riginally stood, and subject to the power of atan; and their imaginations, words, and deeds re evil. Man therefore in this state can know othing aright respecting God; his thoughts nd conceptions of spiritual things being un- rofitable, until he is renewed and quickened y the Holy Spirit. What was lost in Adam is ade up in Christ; and the guilt of Adam's in is not imputed to any until they make it heir own by transgression. There will be a esurrection of the righteous and the wicked, he one to eternal life and blessedness, the other o everlasting misery; and God will judge the orld by Christ Jesus. That the Holy Scrip- ures were written by divine inspiration, and ontain a declaration of all the fundamental octrines and principles relating to eternal life nd salvation; and that whatsoever doctrine or ractice is contrary to them, is to be rejected s false. The society does not call them the Word of God, this term being peculiarly ap- lied, in them, to the Lord Jesus; yet it be- ieves them to be the words of God, written y holy men as they were moved by the Holy Ghost, and that they are able to make wise unto salvation through faith which is in Christ Jesus. It looks upon them as the only fit out- ward judge and test in controversies among Christians, and is very willing that all its doctrines and practices should be tried by them, freely admitting that whatever any profess or do, pretending to be guided by the Spirit, which is contrary to the Scriptures, be condemned as a delusion. As there is one Lord and one faith, so there is one baptism, of which the water baptism of John was a figure. The baptism which saves the soul is not dipping in or sprinkling with water, but the answer of a good conscience toward God, by the resurrection of Jesus Christ. This answer of a good conscience can only be produced by the washing of regeneration and the renewing of the Holy Spirit, transforming the heart and bringing the will into conformity with the will of God. The communion of the body and blood of the Lord Jesus Christ is inward and spiritual, a real participation of his divine nature, through living faith in him and the power of the Holy Spirit, by which the soul is enabled daily to feed upon him and experience spiritual nourishment; the true Christian supper being that set forth in the book of Revelation: "Behold I stand at the door and knock; if any man hear my voice and open the door, I will come in to him, and will sup with him, and he with me."—Divine worship must be performed immediately between the soul and its Maker. No man can do it for another. It is therefore the practice of Friends to sit down in solemn silence to worship God, that each one may strive to gather inward to the gift of divine grace in order to receive ability to worship the Father of spirits in spirit and in truth, and offer to him, through Christ Jesus our holy Mediator, an acceptable sacrifice, whether in silent mental adoration, the public ministry of the gospel, or vocal prayer and thanksgiving. The call, authority, and qualification for gospel ministry are from Christ Jesus alone, who dispenses them to both men and women, as he sees fit, without regard to rank, learning, or human selection and appointment; and they must be received immediately from him through the revelation of his Spirit in the heart. The command, "Freely ye have received, freely give," is of lasting obligation, and the gospel is to be preached without price; hence the society has borne a constant testimony against a paid ministry, which derives its authority from human learning and ordination, which does not acknowledge a dependence for the performance of it upon the renewed motion and aid of the Holy Spirit. War is wholly at variance with the spirit of the gospel, which continually breathes peace on earth and good will to all men. When the reign of the Prince of Peace is set up in the hearts of men, "nation will not lift up sword against nation, nor will men learn war any more." The words of Christ, "Swear not at all," and of the apostle James, "Swear not, neither by heaven, nor earth, nor by any other oath," forbid all swearing of every kind. The fast to which Christians are called is not the observance of any particular day set apart by man, but a continual fasting from sin; and therefore Friends cannot conscientiously join in public fasts or holy days, so called. They hold that under the gospel there is no inherent holiness in one day more than another, but that all are to be kept holy; and they do not pay a superstitious reverence to the first day of the week, but as it is necessary some time should be fixed to meet to worship God, and that men should be free from outward affairs, and that laborers and beasts should have time for rest, and as the primitive Christians used the first day for these purposes, therefore Friends observe that day as a time of rest, and for religious retirement and waiting on God. The enslaving of the human species is entirely opposed to the commands of Christ and the spirit of his religion, and the society bears a testimony against the system; also against the unnecessary use of intoxicating drinks. It enjoins upon its members plainness and simplicity in dress, language, and behavior; moderation in the pursuit of business; and that they discountenance lotteries and games of chance, music, dancing, stage plays, horse races, and all other vain and pernicious amusements and practices.—In the year 1827 a separation took place in the society, in consequence of which some yearly meetings were organized as new and distinct associations. In a printed document issued at Philadelphia, dated 4th month, 21st, 1827, giving reasons for such separation, it is said: "Doctrines held by one part of the society, and which we believe to be sound and edifying, are pronounced by the other part to be unsound and spurious." These doctrines were opinions preached by Elias Hicks, and regarded as invalidating the miraculous conception, divinity, atonement, &c., of the Lord Jesus, and also the divine authority of the Holy Scriptures. Those who approved of E. Hicks and his sentiments were dissatisfied with opposition made to their promulgation and after the separation both parties maintained yearly meetings of their own, each still claiming the name of Friends.—See George Fox's "Journal," Sewell's "History," Barclay's "Apology," and Penn's "Rise and Progress" and "Key."

---

* Under the title FRIENDS, a general view of the history and discipline of that denomination of Christians has been given; and this article, prepared under the authority of the Philadelphia yearly meeting, presents a more specific statement of their religious doctrines, as held by that portion of the body which claims to be the orthodox representative of its original founders.
